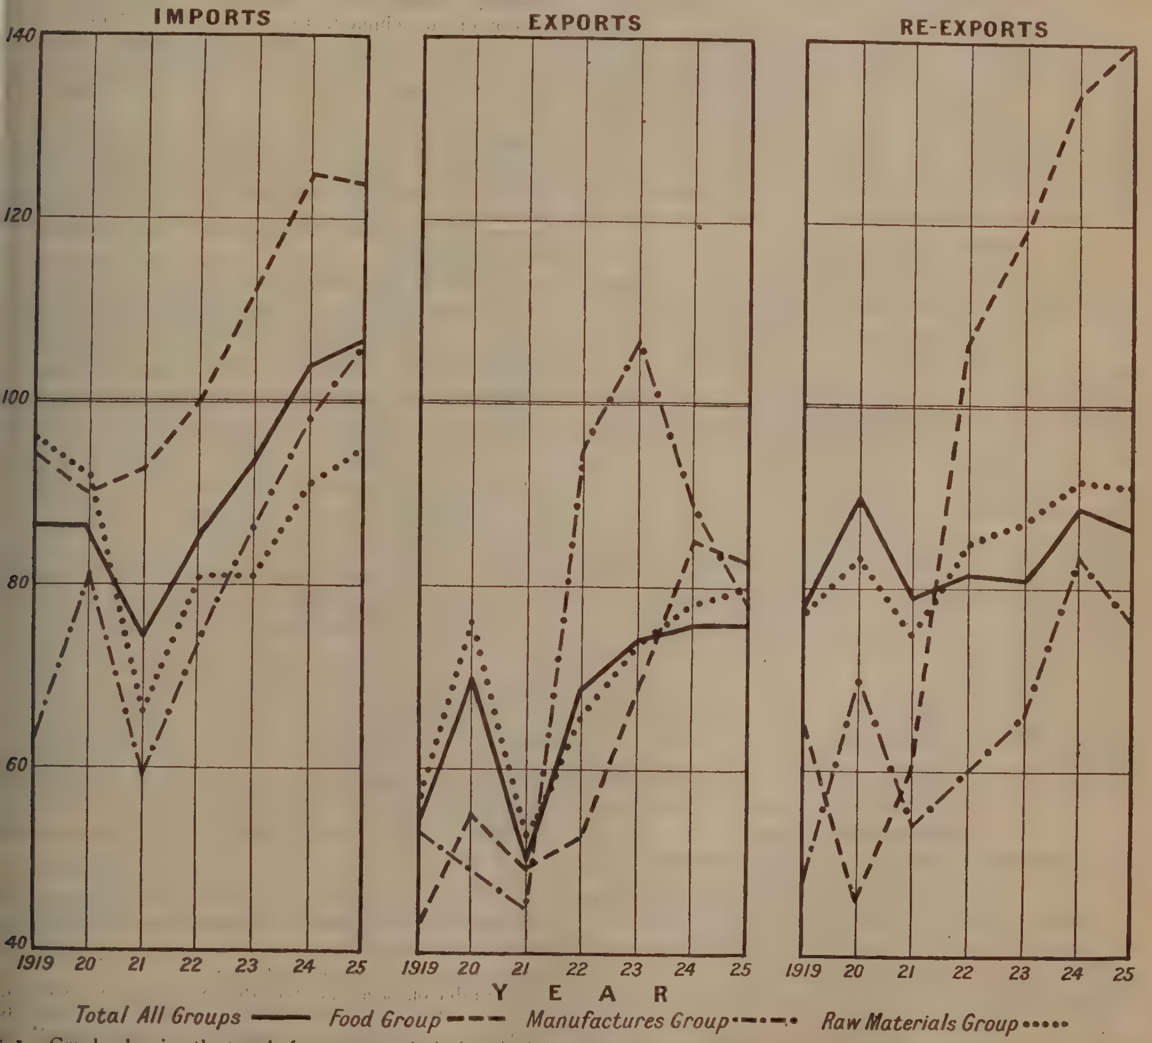
The Slump of 1921.—It will be observed that in the year 1920, in almost every industry, the total value of exports had enormously increased, although the actual quantities exported were



: I.—Graphs showing the trend of overseas trade (volume) of the United Kingdom from 1919 to 1925. The volume in 1913 is taken ual to 100, the volumes for the years 1919 to 1925 being shown as percentages above or below that of 1913.

less than in 1913 by varying degrees, and that this position
suddenly changed in 1921, when the volume of exports fell
fraction of the volume in 1913, though the values continued
be substantially higher. Thereafter quantities gradually
and values fell. The causes of the slump were described as foll
in a report issued by the Federation of British Industries in
year 1922:—

> Although there was, for various reasons, considerable delay in
> resumption of the normal flow of orders for manufactured goods a
> the War, and the intake by the countries normally buying la
> quantities of such goods was during 1919 and 1920 far below
> normal, the demand was more than the capacity of the manufact
> ing countries, hampered and reduced as it was by the effects of
> War, could supply.
>
> At the end of 1918 a boom in manufactured goods was experienc
> in Japan, which passed to the United States, and later in turn
> Great Britain, to France and Belgium and finally to Germany.
> these circumstances, and with Central Europe very largely unable
> import at all, Great Britain was in a relatively fortunate position
> obtaining supplies of food and raw materials. In 1919 the necess
> foreign credit was secured in the first few months by a continua
> of borrowing, and subsequently to a large extent by the very li
> earnings of our shipping and the abnormal prices we were abl
> secure for our coal exports. To the goods we were able to buy in t
> way have to be added the considerable imports on government a
> count ordered during the War, but not shipped till after the Ar
> stice. In 1920 the demand for our manufactured goods was so inten
> that though the tonnage exported was small compared with 19
> the total value was very much larger, the average price being nea
> four times the average pre-War price.
>
> These developments were accentuated by the fact that ma
> countries had heavy accumulated stocks of raw materials which th
> were unable to realise, as these accumulations were largely of ma
> rials normally taken by the Central Empires and other countr
> which were still out of the market. Unable to realise their produc
> these countries in turn were unable to buy the manufactured go
> they required, and the normal circle of commerce was interrupt
> The effect was immediately to prick the bubble of prices. Purchase
> all over the world ceased to buy our goods, and, as prices fell, tend
> to defer purchasing altogether until they could see some sign th
> prices had touched bottom. On the one hand, therefore, man
> facturers were left with high-priced goods for which the dema
> had suddenly ceased, while, on the other hand, there were hea
> accumulations of unsold agricultural products and raw materials
> the hands of potential buyers in distant parts of the world. Th
> has had the result of checking production throughout the world bo
> of agricultural products and manufactured goods.

Another factor which acted as a depressing influence imm
diately the slump commenced (and had, indeed, prevented so
industries from profiting by the boom) was the liquidation
the Government of the enormous stocks of War material held
them at the conclusion of hostilities.

The table on page 273 gives the production of various indu
tries, together with the trend of population in Great Brita
and the outward passenger movement for the periods 1911
1913 and 1919 to 1925.

Production excluding Ireland from 1922. (9) Total wheat retained for home consumption compiled from U.K. trade returns. (10) Estimated population compiled from the annual reports of the Registrar-General. (11) Board of Trade urns.

THE VARIOUS INDUSTRIES

oal.—The story of the coal industry was a particularly un- py one. In 1914, 1,133,746 men were engaged in the coal es of Great Britain, of whom 150,000 approximately joined or war services. At the end of the War there were 1,008,867 in 1924 1,230,248 men in the industry. Immediately after War huge demands for coal arose. During this time due ntion could not be given to maintenance problems, and this, pled with the return of the miners from the armies, created te difficulties in organisation, leading to increased costs with iced outputs. The market showed considerable inequalities, ort prices being extremely high as against home prices. Dur- 1920–1 exports steadily fell, but in 1922–3 there was a sudden sustained improvement, due to the disturbance of conti- tal production through the occupation of the Ruhr. As this or gradually ceased to operate the depression set in again. 1925 the Government appointed a Commission to inquire and report upon the economic position of the industry. ir report was published on March 10 1926 (*see* COAL).

ron and Steel.—The export figures increased very largely in 2, the reason in this case also being the French occupation he Ruhr. When this artificial stimulus was withdrawn the sperity of the industry immediately declined. This decline tinued through 1924 until the last quarter of 1925. The fol- ing statement by the National Federation of Iron and Steel nufacturers summarises the position at the commencement he last quarter of 1925.

last Furnaces in Operation.—There are in the United King- some 480 blast furnaces for the production of pig iron, which he basic material for the manufacture of iron and steel. If demand for pig iron required it, some 360 of these furnaces ld be blowing at one time. In 1913 there was an average of furnaces blowing throughout the year; the maximum number ving at any one time since the War was 303 in Sept. 1920. the present time there are only 129 furnaces in blast, the nber having steadily fallen since May 1923.

ig Iron.—The decrease in the number of furnaces in opera- is naturally reflected in the production of pig iron. Pig reached its maximum production in the year 1913, when 60,300 tons were produced. In 1920 the output amounted ,034,700 tons, but in 1924 this had fallen to 7,307,400 tons n average of 609,000 tons monthly, and this has still further en in the present year, so that the average monthly output the first nine months amounted to only 529,400 tons, the out for Sept. amounting to 448,700 tons.

Steel.—The output of steel ingots and castings in 1913 amounted to 7,664,000 tons, but owing to war needs the steel-making capacity of the country was expanded by approximately 4,000,000 tons per annum, and the country has now the capacity to produce at least 12,000,000 tons annually. In 1920 the output of steel ingots and castings amounted to 9,067,300 tons. In 1924 the output had fallen to 8,201,100 tons, or an average of 683,400 tons monthly, and in the first nine months of 1925 the average was 609,400 tons.

Exports.—The prosperity of the iron and steel industry depends very largely upon the extent of its export trade. In 1913 the total exports of iron and steel amounted to 4,969,200 tons; in 1924 exports were 3,853,100 tons, or an average of 321,100 tons a month, while the average in the first nine months of 1925 was no higher than 300,000 tons a month. In Sept. exports touched their lowest point for 1925 and amounted to 273,200 tons.

Imports.—Imports, on the other hand, have increased in spite of the fact that the increased capacity during the War was sufficient to make it unnecessary for any steel to be imported. Imports of iron and steel in 1913 averaged 186,000 tons a month; in 1924 they had increased to 202,400 tons a month, and in the first nine months of 1925 amounted to 227,000 tons a month.

The decline in this trade has been due to causes which have affected other industries, *i.e.*, depreciated exchanges abroad, lower taxation, lower wages, longer hours in other countries and high foreign tariffs, the difficulties of the steel trade being accentuated by the increase in productive capacity both here and abroad.

Engineering.—In regard to the engineering industry, the same causes were in operation. The year 1925, on the whole, saw an improvement. An unfavourable feature, however, was a rise in the average value of machinery imported in comparison with the average value of machinery exported, showing that the imported goods are of a more highly developed and costly character than those exported. The position of the electrical side of the industry was more satisfactory than that of the other branches, no doubt because of the great increase throughout the world in the consumption of power.

Shipbuilding.—Particularly unfortunate was the experience of the shipbuilding industry. The productive capacity of the world has, since the slump of 1921, been greatly in excess of demand, due to the extension of plant throughout the world necessitated by the rapid wastage of tonnage during the War, and also to the continued depression of international trade which reduced the demand for freight.

otton.—The position of the American section of the cotton
e was continually unsatisfactory. Owing to short cotton
s the price of material was so high that the relatively poor
kets, in which the great majority of sales are made, were
illing to pay the prices which manufacturers were compelled
sk. Here again the year 1925 gave promise of an improve-
t. In regard to the finer side of the trade, that using Egyp-
cotton, the raw material supply was more satisfactory, and
e was consequently better. Moreover, this side of the in-
ry suffered less than the American section from the tendency
cotton-growing countries to install spinning machinery.
ily, reference should be made to the policy of recapitalisation
igher values during the boom period, the subsequent effects
hich seriously embarrassed a number of firms (*see* COTTON).

ool.—In regard to the woollen and worsted industry, there
very rapid recovery of trade in the second half of 1921, which
tinued, subject to a slight setback at the end of that year,
ugh 1922 and 1923, the demand generally being for the finer
s of goods at the expense of lower grade. During 1923 there
a further setback largely due to the disturbance in conti-
tal trade through the Ruhr occupation, which had so sub-
tially benefited the iron and steel and coal industries. During
first half of 1924 there was a gradual recovery, which, how-
r, affected the heavy more than the finer goods; but in the
nd half of that year the depression returned, and continued
ing the opening of the year 1925. In the latter part of 1925
e were signs of recovery. In this industry, as well as in cot-
, there was a world shortage of material which maintained
es at a relatively high level, and was detrimental to consump-
in the impoverished state of most markets. In neither wool
cotton had the policy of central control, initiated during the
r, maintained its power (*see* WOOL).

hemicals.—The chemical industry includes heavy chemicals,
stuffs and intermediates, fine chemicals and fertilisers. The
gress of the heavy chemical trades since the War was ex-
nely variable, as is shown by the export figures in the above
les. These have been chosen as samples, the great variety of
ducts in the industry making any general statistical state-
t impossible.

yestuffs and Intermediates.—At the outbreak of War less
n 20% of the colours used here were actually made in Great
tain, the market being dominated by the German industry.
cessation of imports soon created a dye famine, and prices
to unprecedented heights, to the great injury of the textile
other dye-using industries. By the end of the War, however,
tish makers were able to supply not only their own essential
uirements, but also some of the needs of our Allies. Govern-
nt assistance and finance were necessary to enable this result
be attained. In addition the Government assisted the for-
tion of a new company called the British Dyestuffs Corpora-
, Ltd., an amalgamation of various existing concerns, and
f invested a large sum in the corporation. In 1925 it was
med that the British industry was meeting 80% of the needs
British colour users, and that an average reduction of 50%
rices had been effected since 1921. The working of this sys-
of protection and partial Government control had not, how-
r, been altogether happy, and during 1925 a reorganisation
carried through, the Government giving up its shareholding
he corporation.

ine Chemicals.—The following summary is taken from
volume *Chemicals* by Ashe and Boorman (Ernest Benn, Ltd.
4) in the series, on *The Resources of the British Empire:*—

> rior to 1914 the fine chemical industry was practically a monop-
> of Germany, although several British firms possessed an inter-
> onal reputation for some of their products. The War cut off
> rely our normal supplies of all kinds of fine chemicals, and beyond
> stocks in the country we had no means of obtaining supplies of
> s such as aspirin; of anaesthetics such as novocaine; of remedies
> as salvarsan; of synthetic photographic chemicals which were
> to aerial photography and for X-ray work in the hospitals; of
> hetic tannins required in the leather industry; of analytical
> ents for chemical analysis in the great steel works and in prac-
> lly every other industry; and of a variety of other fine chemicals
> ssary for research work and in industry. Fine chemical manufacture was hurriedly undertaken in Great Britain, under most adverse conditions in respect of buildings, plant and processes, and very substantial progress was made. In a few months British salvarsan and salicylic acid were on the market; other drugs soon followed, and before hostilities ceased there was scarcely a synthetic drug of real importance that was not made in this country in sufficient quantities, and in many cases with a margin for export. The same was true of the synthetic photographic chemicals, amidol, metol, paramidol and glycin, and at the present time British photographic chemicals are second to none in quality. Of the synthetic perfumes and flavourings a certain number were made here before the War, but since the production has been largely developed. At the end of 1925 it was estimated that the British production was thrice as great and the volume of exports double what it had been before the War.

Fertilisers.—The fertiliser industries, producing basic slag, sulphate of ammonia and superphosphate of lime suffered much from the agricultural depression, due to bad harvests throughout the world, and from the fact that many of the products are the by-products of other industries. Before leaving the chemical industry mention must be made of the successful establishment since the War of a large scale plant for the fixation of nitrogen by synthetic process; this is a matter of great importance as Great Britain was previously entirely dependent on imports of nitrate of soda.

Motorcars.—The progress of this industry is well illustrated by the tables given above. Satisfactory features were the increased exports in 1923–4 and reduction of imports in 1924. It may be noted that a 33⅓% *ad valorem* duty on imported motor cars, components and accessories was imposed in 1917, removed in July 1924 and reimposed in July 1925.

Artificial Silk.—Before the War artificial silk was not regarded as of sufficient importance to be allowed a special heading in official statistics. The figures given above show how prominent a place the trade held in Great Britain in 1925. It must be remembered that the figures represent values only, and that prices fell during the period 1921–5 (*see* ARTIFICIAL SILK).

Sugar Beet.—The development of the sugar-beet industry in Great Britain is in too early a stage to make any statistical record possible. The Government pledged itself to a generous scheme of subsidy, and the new industry started under favourable auspices. At the end of 1925 there were 10 factories actually in operation.

VII. AGRICULTURE

The period 1911–25 witnessed great changes in the cultivation of the soil, in the prices of agricultural produce, in the ownership of land, and still more in the relation of the State to the industry. Indeed, the period witnessed the popular acceptation of the idea that agriculture stood on a different footing from other industries and as such demanded that the State should have a "policy" calculated in one way or another to encourage the full cultivation of the soil.

Before the World War, Government action was of a very limited character. Its most important function was the eradication of contagious diseases of animals in continuation of the policy begun in the '60s for the prevention of the spread of foot-and-mouth disease, cattle pleuro-pneumonia, swine fever and rabies. A beginning had, it is true, been made in promoting agricultural education and research, in the extension of small holdings, and in the improvement of light horse breeding, but generally in this period the policy of the Government, apart from the suppression of animal diseases, was one of non-interference with the industry, combined with some tentative efforts towards education and the spread of information.

The War Period.—With the outbreak of war, agriculture assumed a new significance. It ceased, at least for the time being, to be an industry pursued, like other occupations, entirely for the benefit of those engaged in it. The production of food became a national question. For a time it seemed as though the increased prices would in themselves provide sufficient stimulus, and it was not immediately obvious in what direction the State could usefully intervene. Gradually, both the food and labour supply became increasingly difficult, and in Jan. 1917 the Food Production Department was established under the Board of Agriculture with a view to more active steps being taken through county war agricultural committees and otherwise to stimulate the cultivation of the soil.

The Corn Production Act.—In the following March the Government announced an entirely new policy, which was afterwards incorporated in the Corn Production Act, 1917. This new policy was based on the view that in order to get farmers to plough up grass land and grow more cereals it was necessary to give them confidence in the future course of prices by providing a Government guarantee that the prices of wheat and oats should not fall below a certain figure during the next few years. The Act, as ultimately passed in Aug. 1917, fixed the prices as follows:—for 1917, wheat 60s. and oats 38s. 6d. per imperial quarter; for 1918–9, 55s. and 32s.; and for 1920–1–2, 45s. and 24s. respectively. Provision was made for the payment to the grower of the average difference between these prices and the average price ruling in the seven months following the harvest in each year. These guarantees, however, never became operative, as the actual price throughout the period was above the guaranteed price. Apart from the guarantees, the Act embodied another new and important departure in policy by providing for the establishment of an agricultural wages board, whose duty it was to fix minimum wages for workmen in agriculture and to see that not less than these wages were paid. This was combined with restrictions on the raising by land-owners of agricultural rents, and with power to enforce the proper cultivation of the land by farmers. Thus the policy contained in this Act was of a dual character: on the one hand it ensured to farmers for a period of six years certain minimum prices for their two principal cereal crops and protected them against any undue raising of rents; on the other hand it required them to pay adequate minimum wages to their workers and to cultivate their land in accordance with the rules of good husbandry.

As a policy of a less permanent character, very active steps were taken by the Food Production Department (under Lord Lee) during 1917–9 in the direction of increasing the area under the plough and generally in promoting the output of food. The increase in the area of the corn and potato crops between 1916 and 1918 was over 1,500,000 acres in England and Wales alone, while the total increase in the United Kingdom was just on 3,000,000 acres.

The Selborne Committee.—In the meantime, the question of the policy to be adopted in regard to agriculture after the War had been considered by the Agricultural Policy Sub-Committee, of which Lord Selborne was chairman. The reference to this committee was "to consider the methods of effecting an increase in the home-grown food supplies, having regard to the need of such increase in the interests of national security," and their report was issued in July 1918. It contains a full exposition of the position of agriculture in this country and deals in detail with the various problems presented, the object being "to formulate a scheme of agricultural policy which may be generally accepted by the nation and adhered to through a long course of years." Briefly, the committee took the view that the security and welfare of the State demanded that agricultural land should be made to yield its maximum production of foodstuffs, and that if this object was to be attained it was necessary to provide a basis of security and stability in the conditions under which agriculture is carried on. The method they recommended was the permanent adoption of the principles underlying the
Production Act, viz.: a minimum wage for the agricultu
labourer, a guaranteed minimum price for wheat and oats
the farmer, and a control of cultivation sufficient to ensure
the State a permanent development of agriculture and
proper utilisation of the land.

These principles were incorporated in the Agriculture
which, after prolonged discussion, was passed on Dec. 23 19
The minimum prices guaranteed under this Act were to be as
tained annually on the basis of the estimated cost of product
in any year as compared with 1919. Within a few months of
passing of the Act, however, it became apparent that a seri
slump in agricultural prices was taking place and that the bur
on the State involved in the guaranteed prices would be
large. This was combined with a general financial stringe
which demanded a reduction in all Government expenditure

A Reversal of Policy.—The result was that the main operat
clauses of the Agriculture Act, 1920, were repealed by the
Production (Repeal) Act, 1921, and the whole policy of
the intervention of the State in agricultural wages, prices
in the control of cultivation was abandoned. Some tempor
compensation was given to farmers by the payment of a subs
on wheat and oats grown in 1921, which amounted to the
of £18,000,000, and the sum of £1,000,000 was added to
development fund, mainly for the purpose of promoting
cultural education and research. The Agricultural Wages Bo
was abolished, and in its place conciliation committees represe
ing both employers and workers were established to fix wa
by voluntary agreement.

Between 1921 and the end of 1925, a great deal of discuss
took place as to the adoption of some national policy in reg
to agriculture, and a large number of proposals were put
ward. A conference representative of the various interests
proposed with the object of arriving at some agreed met
which would be acceptable to all parties and shades of poli
opinion, but owing to preliminary differences this confere
was never held. The Council of Agriculture, which is a sta
tory but unofficial body, proposed a scheme which, among o
matters, involved a subsidy amounting to some £5,000,00
£6,000,000 for the encouragement of arable cultivation in
land and Wales, but public opinion appeared generally to
opposed to subsidies of any kind.

Thus, at the end of 1925 there was no broad national po
recognised by the State in regard to agriculture of a chara
comparable with what was attempted by the Corn Produc
Acts. On the other hand, between 1921 and 1925 a great m
agricultural questions were dealt with separately, and
extensive action was taken by the State in the direction of
tering and promoting agriculture. Very considerable sums
voted annually by Parliament with this object, and the posi
may be summed up by saying that policy is in the directio
helping the farmer to help himself without the interventio
the Government either in regard to prices or cultivation.

Agricultural Wages.—In regard to agricultural wages,
State again intervened and by the Agricultural Wages Reg
tion Act, 1924, provided machinery whereby minimum w
for workers in agriculture must be fixed in England and W
It was not thought necessary to include Scotland in its provis
because Scottish workers appeared able to arrive at satisfac
agreements with their employers without any assistance.
English Act provides for wages to be fixed locally by 47
mittees covering the whole country, each committee being
posed of an equal number of employers and workers (us
six to eight on each side), two impartial members appointe
the Minister of Agriculture and a chairman. In the even
failure to agree, an agricultural wages board similarly co
tuted has power to act in default.

Apart from this action in regard to labour, the newer feat
of the agricultural policy are the action taken in regard to
settlement, education and research, and sugar beet, to
may be added the enquiries and investigations carried ou
the first instance by the Linlithgow committee and subseque

by the Ministry of Agriculture in regard to the marketing of agricultural produce. Combined with these developments is a continuance of the older policy in regard to the control of contagious animal diseases, more especially foot-and-mouth disease, which of late years has presented a more formidable problem than it did for a long period prior to the World War.

Land Settlement, Education and Research.—A forward movement was begun after the Armistice in the direction of settling ex-service men on the land, and under the Land Settlement (Facilities) Act the area of land in England and Wales held by public authorities for letting as small holdings was more than doubled, viz.: from 201,000 ac. at the end of 1918 to 447,000 ac. at the end of 1924, while the number of occupiers increased from 13,874 to 30,177. As regards research and education enormous progress has been made, research institutes (connected in most cases with universities) being now provided for the study of all the scientific sides of agriculture, while instruction of a practical character is undertaken under the direction of the local authorities in every county in the country. This work is maintained or aided by grants from the Ministry of Agriculture, the expenditure from Parliamentary funds in England and Wales alone in 1925–6 amounting approximately to £647,000.

Another direction in which Parliament is providing large funds for the assistance of agriculture is by encouraging the establishment of the sugar beet industry by subsidising the manufacture of sugar from home-grown beet for a period of 10 years under the British Sugar (Subsidy) Act, 1925. The acreage under this crop rose to 55,000 ac. in 1925, and it was expected that this figure would be doubled in 1926. Considerable expenditure is also incurred in the direction of the improvement of livestock. An attempt was made under the Agricultural Credits Act, 1923, to establish a scheme of co-operative credit societies aided by loans from the State, but the number of societies actually established is very small (*see* CO-OPERATION).

The change in the attitude of Parliament towards agriculture may to some extent be measured by the change in expenditure. Thus in 1911–2, the total expenditure of the Board of Agriculture and Fisheries was £251,000, of which possibly 10% represented expenditure on fisheries. This covered England and Wales and Scotland. In 1925–6, the gross estimate for the Ministry of Agriculture (excluding expenditure on fisheries) was £3,277,000 for England and Wales alone, while the estimate for the Board of Agriculture for Scotland amounted to £452,000. The bulk of this expenditure took the form of grants for the purposes mentioned above and involved in most cases considerable additional expenditure on the part of local authorities and others.

A factor which has vitally affected both agriculture itself and the policy of the State has been the change in the price of agricultural produce since the War. During the War, prices naturally rose very considerably, and the rise continued till towards the end of 1920. In the middle of 1921 a severe and continuous slump set in, with the result that the prices of agricultural produce generally, which were 202% above pre-War prices in Sept. 1920, fell to 57% above in Sept. 1922, and with some fluctuations remained more or less at this level for the next three years, the figure for Nov. 1925 being 53%. The sudden fall in prices resulted in severe capital losses, and made agriculture, at any rate for a time, a very precarious undertaking (*see* AGRICULTURE).

In this connection, reference may also be made to another factor connected with the change in the value of money. The prevailing system of tenure in Great Britain is that of landlord and tenant, whereby the land and buildings are provided and maintained by the landlord at a rent which is generally admitted to give only a very small return by way of interest on the capital represented. The much higher rate of interest obtainable during the post-War period on first class securities led to extensive sales of estates, and is said to be resulting in a gradual change in the older system in the direction of a greater tendency towards occupying ownership. Such statistics as are available suggest that the percentage of land occupied and farmed by the owner increased from about 15% in 1920 to 25% in 1924.

Changes in Cultivation.—The changes in cultivation in Great Britain in the 14 years 1911 to 1925 reflect the policy of the period. Up to 1916 there was little development; in 1917 the pressure for increased food production began to make itself felt and reached its maximum intensity in the following year. With the close of the War the impetus was lost, and the proportion of land under the plough gradually decreased and fell below the pre-War level. The following figures, in thousands of acres, show the changes in Great Britain from 1911 to 1925:—

Acreage under Crops and Grass (000's omitted)

	Corn Crops	Arable Land	Permanent Grass	Total Acreage under Crops and Grass
1911	7,041	14,648	17,447	32,095
1917	7,308	14,606	17,251	31,858
1918	8,974	15,852	15,896	31,749
1925	6,321	13,912	16,549	30,461

The decline in the total acreage under crops and grass is to some extent compensated by an increase in mountain and heath land and rough grazings not included under that heading. The area under wheat (included in the above table under corn crops) which was 1,906,000 in 1911, reached a maximum of 2,636,000 ac. in 1918, and declined to 1,547,000 ac. in 1925. In regard to livestock, a very striking feature was the way in which on the whole the flocks and herds were maintained during the War, notwithstanding the shortage of feeding-stuffs. From 1916 to 1920, however, there was a quite noticeable decline in the number of sheep, part of which has since been recovered. As compared with pre-War years cattle are somewhat more numerous, while the pig population, always a fluctuating factor, reached a maximum in 1924. As a broad indication of the magnitude of the industry it may be mentioned that the total value of the "output" of agricultural land in Great Britain represented by the produce sold off farms for consumption elsewhere was estimated in 1923 at £259,000,000.

Agricultural Policy in 1926.—In Feb. 1926 the Government issued a considered statement on agricultural policy, which declared that the Government was not prepared to recommend subsidies for the increase of corn growing or arable cultivation and that it was definitely opposed to compulsory control of cultivation. "The right course in the best interests of the industry itself and of the nation as a whole is to proceed on the lines of education and encouragement rather than of coercion, to endeavour to create that confidence which is essential for progress, to stimulate the private enterprise of those engaged in the industry, and to assist them to organise themselves on an economic basis." It then went on to indicate the lines on which the Government would proceed, such as the development of agricultural credit, small holdings, afforestation, land drainage, marketing of agricultural produce, housing in rural areas, protection against disease and the development of sugar beet cultivation.

(R. J. T.)

VIII. COMMUNICATIONS AND TRANSPORT

At the outbreak of the War the Government took complete control of the railways under an agreement whereby the companies were guaranteed their pre-War revenues. The fact that the War lasted for more than four years, and involved a far-reaching rearrangement and redistribution of the trade and traffic of the country, made the strict terms of the agreement practically inapplicable. A huge sum of money was required to put the companies back into their pre-War condition of repair and efficiency. Rolling stock had been removed to other countries, stations closed, permanent way and other plant allowed to fall into comparative disrepair, staff seriously depleted, and the arrangements for the routing of traffic widely altered. The costs of operation had also risen enormously.

The Ministry of Transport.—The Government, foreseeing the difficulties which would arise if control were suddenly removed, passed in 1919 the Ministry of Transport Act, which gave the Minister powers to control the operation of all existing means of internal transport. One provision in the Act has proved of permanent importance. This was section 21, which provided for the setting up of the Rates Advisory Committee composed of five members: one person of legal experience (to be chairman), two representatives of trading and agricultural interests, one representative of transport interests, and one representative of labour. It was laid down that before directing any revision of charges, etc., the Minister should consult this committee.

The Act was immediately followed by a reference from the Minister to the committee to report upon an interim revision of railway rates for merchandise and minerals. The committee reported in favour of a general increase varying according to class from 25 to 60%, with flat rate additions, and increased charges for collection and delivery. This was brought into operation on Jan. 15 1920. On May 11 the Minister announced his determination to undertake to complete revision of railway charges and invited the committee to report on the general principles which should govern the revision, including the classification of merchandise traffic. Meanwhile he directed the increase of rates up to 100% above pre-War as from Sept. 1 1920.

As a result of the committee's general report, there was finally passed the Railways Act 1921, which had the effect of entirely reorganising the railway system of the country. The Act's most important provisions may be summarised as follows:—

1. The railways of Great Britain were amalgamated into four large groups, the Southern, the Great Western, the London, Midland and Scottish and the London and North Eastern.
2. A new tribunal called the "Railway Rates Tribunal" was set up to which almost all the powers of the Railway and Canal Commission and many new powers were entrusted, its most important function being the settlement of the schedules and charges of the amalgamated companies. The tribunal consists of one person of legal experience, who is chairman, one person of railway experience and one of commercial experience, and is obviously the successor of the Rates Advisory Committee.

The first of these provisions was intended to facilitate working economies by eliminating costly competition, and the second to provide a cheap and business-like tribunal for exercising the necessary control over the new system

Charges and Wages.—The Act laid down an entirely novel principle in regard to the basis of charge. Section 58 provides that the charges be fixed on a basis estimated to yield an annual net revenue ("the standard revenue") equivalent to the aggregate net revenues in the year 1913 of the various companies absorbed by the amalgamated company together with allowances for interest on capital expended or raised since Jan. 1 1913, or capital which had not at that date become fully remunerative. Section 59 provides for periodical revisions of the charges and also lays down that if on any such review the tribunal finds that the net revenue of the company is substantially in excess of the standard revenue, such excess shall be divided between the public and the railway companies, 80 % being allocated to reduction of charges and 20 % being retained by the company as profits. This increased standard (the old standard plus 20 % of the excess) is then to become the standard revenue of the company.

The tribunal was also given power to revise the classification of goods, and some control was vested in it of exceptional rates. There is no doubt that the framers of the Bill intended, by extending the number of classes and instituting a strict revision of exceptional rates, to reduce the complexity of the rate books, which were said to include more than 80,000,000 exceptional rates, many of them obsolete. The powers which the Bill proposed to vest in the tribunal for this purpose were however strenuously opposed by both traders and railway companies, and, although the tribunal has increased the number of classes from 8 to 21, it is improbable that the new provisions will succeed in substantially reducing the number of effective exceptional rates. In regard to wages and provisions of service, the Act provides that all disputes in regard to these shall be referred to two bodies, the Central Wages Board and the National Wages Board, the latter acting as a court of appeal from the former. Both these bodies are in the nature of conciliation committees including representatives of the companies and their employees; the National Wages Board also includes representatives of railway users.

Between the passing of the Act and the end of 1925, the Railway Rates Tribunal was more or less continually involved in the carrying out of the reorganisation of the railway system entrusted to it by the Act. The ascertainment of the standard revenue proved a very great difficulty, and might indeed have proved impossible but fo the formation of a committee known as the traders' co-ordinatin committee, representative of all trades substantially interested i railway traffic, and of such great organisations as the Federation British Industries, the Association of British Chambers of Commerce etc. This committee has been legally represented before the Tribuna and has been able to negotiate settlements with the railway companies. It appears likely that the almost insuperable difficulties involved in the application of the Act will be surmounted in this way Reverting to the question of charges, these have been reduced b successive concessions in 1922 and 1923, till at the beginning of 192 they were 50 % above pre-War, with certain flat rate additions, som of the heavy traffic standing at 40 %.

In July 1914 the railway trades unions were preparing a claim fo improvement of conditions and increase of wages, to be presented i Nov. 1914, when an existing agreement was due to run out. On th outbreak of War it was agreed between the unions and the companies that the existing agreement should continue, but should b terminable by six weeks' notice on either side. The government during the War granted various increases of wages, and in Nov. 191 the unions gave notice to terminate the agreement. There followe a prolonged negotiation in which the unions, the companies and th government were all involved, and on Sept. 26 1919 500,000 railwa workers came out on strike. Work and negotiations were resume on Oct. 5, and an agreement reached on March 20 1920. Under thi rates were divided into two classes, "A" rates and "B" rates. Th "A" rates represented the pre-War rates plus certain flat rate additions. These latter were to be subject to adjustment according t the cost of living. The "B" rates represented practically the pre-Wa wages plus 100 %, and it was agreed that, whatever the change i the cost of living, wages should not fall below this level. In 192 the railway unions put forward claims for a general increase o wages, and the companies counter-claimed for a general reduction The National Wages Board rejected both claims, but provided tha new entrants into the railway service should no longer be entitled t the benefit of the "A" rates. The Board also stated that they di not regard the "B" rates as an "irreducible minimum."

The Removal of Control.—The position of the companies afte the removal of Government control in 1921 was an unfavourabl one. The economies promised through amalgamation were slo in materialising, and the trade depression resulted in a declin of traffic which was only temporarily alleviated by the grea increase in the iron and steel and coal traffic caused by the French occupation of the Ruhr. At the same time the rapid increase o road transport has diverted from the rail a considerable an increasing volume of the high grade traffics which were the mos lucrative to the railways, whose position has been further complicated by the great increase in working costs. Expenditur in 1924 exceeded that of 1913 by £96,000,000 or 117 %, wherea to meet this additional burden receipts had only increased by £88,000,000 or 70 %. Coal was 142 % higher than in 1911 and 89 % over 1913; other materials were 67·9 % and wages 153 % above 1913. There was an increase in staff due to the operation of the eight hours' day, the staff in the four amalgamated companies having increased by 76,000 or 13 %.

The companies' financial position was, however, relieved by the fact that in 1922 the Government, in order to clear up claims for compensation under the control scheme, handed over to them sums amounting in all to £62,000,000, making over £100,000,000 so distributed since the beginning of control. The companies were able in the years 1923 and 1924 to maintain their dividends by drawing money (over £5,000,000 in 1924–5) from their reserve funds, which had been enormously augmented by these grants. It should be mentioned that the companies have made efforts to secure legislation enabling them to carry by road, but hitherto without success. Meanwhile, they are no doubt endeavouring to effect economies in their operating expenditure. Electrification schemes are being put in hand, notably by the Southern Company. The L.&N.E.R. and the G.W.R. have taken steps to increase the size of the mineral trucks on their systems, the ideal apparently being a 20 ton standard; and passenger services are being co-ordinated, etc. Attempts are also being made to obtain relief from the burden of local rates.

Canals.—During the War the Government took over the great bulk of the canals, the object being to relieve the railways as far as possible of traffic which could equally well go by water. The arrangements for compensation were similar to those made with the railway companies. The great value of the canals during the War caused a revival of interest in their potentialities, especially as the railway system was very congested during the early post-War period. The government instituted inquiries into the possibility of reviving the canals which had largely fallen into disuse prior to the War, but no government felt justified in undertaking the somewhat ambitious schemes of reorganisation which have been recommended at various times. Local schemes, have, however, been under consideration in various districts, and with government and municipal assistance important improvements are being made on the waterways between Nottingham and the Humber. It is possible that further developments may be undertaken, notably between Birmingham and the Mersey, and Birmingham and the Severn.

Roads.—The development of road transport during the first decade of the 20th century directed attention to the condition of the roads in the country, and as a result the Development and Road Improvement Funds Act was passed in 1909. Under this Act a Road Board was constituted with powers:—

(*a*) To make advances to county councils and other highway authorities in respect of the construction of new roads or the improvement of existing roads;

(*b*) To construct and maintain any new roads.

The income of the Road Improvement Fund was to be derived from motor spirit and carriage licence duties. During the World War the income was absorbed into the general revenue of the country and road development was arrested. By an order in council dated Sept. 22 1919 the powers and duties of the Road Board were transferred to the Ministry of Transport. In 1919–20 a special fund of £10,536,000 was set aside for the road and bridge programme, and arterial road construction actively proceeded with, particularly in the London area. Under the Finance Act 1920 a new system of taxation, registration and licensing of mechanically propelled vehicles was introduced and came into force on Jan. 1 1921. Special schemes were put in hand for the relief of unemployment, for which £4,000,000 was provided from the Road Fund in 1920–1. The income of the Road Fund in 1922–3, derived from motor spirit duties, carriage licenses, Exchequer grants and motor taxation, was £12,802,754: these receipts had increased in 1924–5 to £15,234,225. During the period 1919–25 arterial roads were constructed in the London area, Scotland, etc.; the total length of new construction was 169 miles, and 48 miles of existing roads were widened. On March 31 1925 the total commitments of the Road Fund amounted to £36,087,000. Expenditure by local authorities on the maintenance, improvement, etc., of roads increased from £18,903,840 in 1913–4 to £28,413,674 in 1919–20 and to £45,431,036 in 1921–2. The great increase during the post-War period was due partly to the practical cessation of work during the war period and partly to local unemployment relief schemes. After 1921–2 expenditure by local authorities was considerably reduced.

Postal Service.—Telephone tariffs varied widely in different areas in 1910, but by 1921 a system of uniform charges had been instituted as far as possible. The National Telephone Company's system was transferred to the Post Office on Jan. 1 1912. The number of exchanges increased from 1,566 in 1910 to 3,971 on Dec. 31 1925, and the number of telephone stations from 619,399 in 1910 to 1,357,908 on Dec. 31 1925. The acceptance of telegrams from subscribers by telephone, and delivery to them by the same means increased greatly between 1910 and 1925. Rates for inland telegrams on Sept. 1 1920 were double those of 1910.

The following table shows the more important alterations in postage rates between 1910 and 1925:—

Changes in Postal Rates

	1910	June 1918	June 1920	June 1921	May 1922
Initial letter rate (inland and imperial) .	1d.	1½d.	2d.	2d.	1½d.
Initial letter rate (foreign)	2½d.	2½d.	2½d.	3d.	2½d. (May 1923)
Postcard rate (inland)	½d.	1d.	1d.	1½d.	1d.
Initial printed paper rate	½d.	½d.	½d.	1d.	½d.
Inland parcel rate (up to 2 lb.) . . .	4d.	6d.	9d.	9d.	6d. (May 1923)
Inland parcel rate (up to 11 lb.) . . .	11d.	1s.	1s. 6d.	1s. 6d.	1s. 3d. (May 1923)

Air Mails.—The post-War period was marked by the development of commercial aviation. The Post Office inaugurated air mail and parcel services between London and the Continent. Mails are accepted by the air mail for Belgium, France, Morocco, Algeria, Germany, Denmark, Norway, Sweden, etc.; air services established in Continental countries are used to supplement this service. The total weight of letter mail despatched by air in 1925 was 15,520 pounds. The air parcel service carried during that year 50,000 lb. of parcel air mails to Paris, Holland and Germany including the Rhine Army.

Wireless and Cables.—Wireless services considerably increased between 1910 and 1926. A new wireless station was built at Hillmorton, near Rugby, and was opened for service from Jan. 30 1926. This station was able to send messages which could be picked up by ships at sea and by every efficient receiving station in the world. In 1925 the British Govt. owned and worked two cables between Great Britain and Halifax, Nova Scotia. One, in German ownership before the War, is worked directly between London and Halifax. The other, purchased from the Direct United States Co., and taken over by the British Post Office in 1922, is worked from London to Newfoundland and Halifax. The two cables are called the imperial cables.

V., Ch. 55)*; *Reports of the Proceedings of the Road Board* (annual, 1911, etc.); *Report of the Imperial Wireless Telegraphy Committee 1919–20* (cmd. 777 of 1920 and cmd. 2060 of 1924); *Report of the Wireless Telegraphy Commission, 1922* (cmd. 1572 of 1922); *Report of the Broadcasting Committee, 1923* (cmd. 1951 of 1923 and cmd. 2599 of 1925). (C. T.)

GREAT LAKES AND ST. LAWRENCE (*see* 12.399 and 24.21).—The Great Lakes and the St. Lawrence form one of the greatest and most important transportation routes in the world, rivalling in tonnage and economy of operation any other existing water transportation route. To July 1 1924 the United States Federal Govt. had expended about $150,000,000 for improvements in the Great Lakes-St. Lawrence system, exclusive of expenditures by Canada, by States or Provinces and by municipalities.

Traffic.—During the 30 years 1895–1925 over 1,500 million tons of freight moved through the locks at Sault Ste. Marie alone. The 72,000,000 tons which passed through these locks in 1924 included 13,500,000 tons of flour and grain and 42,500,000 of ore, moving east, and 13,500,000 tons of coal moving west. Except for the construction of several experimental Diesel engine-driven vessels, no great developments were made in the type of the large bulk freighter in the 15-year period ending in 1925. The highly specialised freight-handling equipment at the terminals, which has in large measure accounted for the economic system of transfer, has developed only in size during the same period. The record for handling cargo between shore and ship is 16½ min. for loading 12,508 gross tons of ore and 3 hr. 5 min. for unloading.

During the 20 years 1905–25 a considerable tonnage in limestone and sulphur grew up. The stone, used as a flux in ore furnaces, is transported on self-unloading vessels between harbours on Lake Huron and the great iron and steel centres in the vicinity of Lakes Michigan and Erie. Sulphur is carried by water from the wells in Texas and Louisiana to New York, and thence in barges through the New York State barge canal to Buffalo, Cleveland and other points on the Great Lakes. Package freight on the Great Lakes has not kept pace with bulk freight, though still amounting to over 1,000,000 tons. Over 90% of the commerce has been confined to the upper lakes, a small portion only passing into Lake Ontario and the St. Lawrence. Traffic on the upper lakes has increased to such an extent that the locks at Sault Ste. Marie in existence in 1910 (two American and one Canadian) were not sufficient to cope with the traffic, and two new locks (numbered 3 and 4) were constructed on the American side and put in operation in 1918. Each of the new locks is 1,350 ft. long and 80 ft. wide, with 24½ ft. of water over the sill. The old Weitzel lock has not been in operation since 1918.

Harbours.—Originally the mouths of rivers were used as harbours on the lakes. It was necessary to dig out the bars which usually formed at the lake entrance, and later piers were constructed at river mouths which contracted the area of flow and tended to keep the channels scoured out. Still later, breakwaters were built in the lakes to protect pier entrances from wave action. As conditions became more congested in the rivers, the breakwaters were extended to form large outer harbours. These structures were originally stone-filled timber cribs, the tops of which, after the timber decayed, were replaced by concrete or stone. The more recently constructed breakwaters are formed of a line of concrete caissons sunk side by side, or of a long rubble mound composed of stones varying from half a ton to 10 and 12 tons in weight, more or less carefully placed. Some of these outer harbours are as much as four and five m. long and afford ample protection to the largest lake vessels.

Maintenance dredging must be carried on at all times in most of the harbours of the Great Lakes. About 65 harbours on the upper lakes (excluding Lake Ontario) have an authorised project depth of 19 ft. or more at low water; about 65 others on the Great Lakes-St. Lawrence system have been improved so as to be available for smaller vessels.

Connecting Waterways.—The critical points in the navigation of the lakes are the connecting waterways. These, like the harbours, require continuous dredging to preserve project depths and to remove obstructions. The Lake Carriers' Association, a federation including nearly all the owners of freight-carriers on the lakes, have formed an efficient system of communication and supervision which permits them to take advantage of water conditions and load their vessels to the greatest possible depth. The deepening and widening of the connecting channels authorized some years ago have practically been completed; and at many of the most critical points, such as the Neebish channels below Sault Ste. Marie and the channels between Lakes Huron and Erie, separate upbound and downbound passageways are maintained. On the upper lakes the minimum width of channels used for two-way traffic is 500 ft., whereas 293 ft. is the least width of channel now used for one-way traffic. The controlling depth of water between Lakes Erie and Superior is still 20 ft. at low-water datum. A dike on which sluice gates are installed has been constructed across St. Mary's river near Sault Ste. Marie. The gates are operated under the supervision of an international board of control in order to maintain water-levels in Lake Superior and to compensate for diversions on both the Canadian and the American sides at Sault Ste. Marie for power purposes.

The question of diversion of water from Lake Michigan into the Chicago drainage canal for the purpose of sewage disposal has not been settled. The Supreme Court of the United States decided against Chicago in a suit instituted to enjoin the Chicago sanitary district against withdrawing water. However, in order to permit the Chicago Sanitary Commission to prepare plans and construct works necessary to take the place of the prevailing system of sewage disposal, temporary authority to divert 8,500 cu. ft. of water per sec. from Lake Michigan was granted by the United States War Department for a period of five years under certain conditions, which, when carried out, will permit the reduction and perhaps the eventual discontinuance of the diversion for sewage purposes. The question is of importance because of enormous losses claimed by shipping interests on account of lower water levels. It has been stated by government engineers that the diversion of 8,800 ft. from Lake Michigan affects the level of Lake Erie from ·38 to ·43 ft.; of Lakes Michigan and Huron from ·42 to ·44 ft.; and of the St. Lawrence river at lock No. 25 from ·6 to ·65 of a foot.

Erie-Ontario Routes.—Two navigable routes (1926) connect Lake Erie with Lake Ontario. The Erie branch of the New York State barge canal system, completed in 1918, connects Lake Erie and the Niagara river through the Oswego branch of the barge canal with Lake Ontario at Oswego. The barge canal route continues through the State of New York and connects with the Hudson river at Troy, forming a complete waterway available for vessels of less than 12-ft. draft and requiring not more than 15½ ft. of head room. A new Welland canal between Lake Erie and Lake Ontario is being constructed to replace the existing one. It is estimated the work will be completed in 1930. Seven lift locks will replace the 25 locks in the present canal, and the distance between the two lakes will be shortened to 25 miles. The new canal is being excavated to a depth of from 25 to 26½ ft. below Canadian low-water level. The new locks will be 820 ft. long by 80 ft. wide, and, in order to provide for possible future deepening of the canal, will be constructed so as to accommodate vessels drawing 30 ft. of water. The estimated cost of the completed structure is $110,000,000.

The question of improvement of the St. Lawrence river from Lake Ontario to tidewater in the interest of navigation and power development is being seriously considered by joint action of the United States and Canada. The St. Lawrence river affords opportunity for the development of over 4,000,000 H.P. of hydroelectric energy. On account of the many interests involved on both sides of the border, it had been difficult to effect an agreement on the question of the St. Lawrence improvement.

By treaty stipulation the amount of water that may be d verted from the Niagara river for power purposes has been lim ited to 36,000 cu. ft. per sec. on the Canadian side and 20,000 cu ft. per sec. on the United States side. Of the Canadian diversio all but about 10,000 cu. ft. per sec. is used by the Hydroelectri Power Commission of Ontario, in three plants, the largest which, near Queenstown, has a head of over 300 ft. and develop about 500,000 H.P. from the nine turbo-generators installe Of the American diversion practically all the water is utilise by one concern with an installation of over 500,000 horsepowe

Boundary Water Treaty.—In 1909 the United States and Grea Britain signed a treaty known as the " Boundary Water Treaty," whereby the waters between the United States and Canada wer guaranteed free and open to the inhabitants of both countri on equal terms, and principles governing the use of boundar waters were laid down. An international joint commission, cor sisting of three members from Canada and three members fro the United States, was established.

TABLE I.

Lakes	Area of Water Surface	Maximum Recorded Depth	Mean Elevation Approved Low-Water Datum	Ordinary Fluctuations, Water Surface	Average Date of Opening of Navigation	Average Date of Closing of Navigation
	Sq. Miles	Feet	Feet	Feet		
Superior	31,810	1,180	601·6	2·5	April 23	Dec. 9
Michigan	22,400	870	579·6	2·8	April 12	Dec. 15
Huron	23,010	750	579·6	2·6	April 6	Dec. 17

Erie	9,940	210	570·8	3·0	March 29	Dec. 17
Ontario	7,540	738	244·5	3·3	April 5	Dec. 18

TABLE II.

Rivers	Length	Least Width	Greatest Width	Limiting Depth at Low Water	Current in Navigated Portions	Discharge at Mean Stage
	Miles	Feet	Feet	Feet	Miles per Hour	Cubic Foot-Seconds
St. Marys	63	300	24,000	21	1–3½	(1)
Strait of Mackinac	30	10,900	100,000	110	. .	47,000
St. Clair	40	800	5,100	20	1–5	203,000
Detroit	31	1,900	19,000	22	1–6	208,000
Upper Niagara	20	1,500	8,000	10–23	1–7	207,000
Lower Niagara	15	210	2,600	30	1–2½	207,000
St. Lawrence to Montreal	179	1,200	40,000	14	1–6	240,000

[1] In its original condition the mean stage discharge of the S Marys river was about 78,000 cu. foot-seconds. The flow of th river is now entirely controlled by regulating works.

TABLE III.

Commerce (in short tons) on the Great Lakes

Year	Total U.S. Commerce on Great Lakes (Adjusted)	Canals at Sault Ste. Marie (Reported)	Detroit River (Estimated)	Welland Canal (Reported)	St. Lawrence Canals (Reported)	N.Y. State Barge Canal (Reported)
1910	92,044,843	62,363,218	73,526,602	2,326,390	2,760,752	3,073,41
1920	111,139,686	79,282,496	80,410,082	2,276,072	3,067,962	1,421,43
1921	71,460,170	48,259,254	63,973,308	3,076,422	3,734,065	1,457,80
1922	94,038,090	66,067,258	68,497,062	3,391,419	4,319,919	2,260,76
1923	125,517,551	91,379,658	92,170,460	3,755,912	4,541,528	2,572,63
1924	109,831,279	72,037,390	80,073,850	5,037,412	5,536,374	2,658,67

[1] Old canal system partly closed down between 1910 and 1918 du ing construction of a new 12-ft. canal.

[2] Includes 566,351 and 626,357 tons for 1923 and 1924 respe tively of local terminal traffic that did not pass through the canal

(H. T.*)

RECO-TURKISH WAR: *see* BALKAN WARS.

REECE (*see* 12.425), a republic of southern Europe and a mem- of the League of Nations. Its area is 49,200 square miles. area of Old Greece in 1912 was 24,400 square miles. The Bal- Wars of 1912–3 resulted in the addition of New Greece, con- ting of Macedonia, Epirus, Crete and a number of islands in the gean, with an area of about 21,600 sq. m., making the total a of the country about 46,000 sq. m. in 1914. After the World ar, Greece occupied Thrace and a part of the vilayet of Aidin Asia Minor, and these occupations were confirmed by the aties of Neuilly and Sèvres. But, as the result of the Asia nor campaign, Greece in 1922 evacuated Asia Minor and stern Thrace in favour of Turkey, and by the Treaty of Lau- ne in 1923 she also retroceded Imbros and Tenedos. The a of Greece after these various changes, is now about 49,200 uare miles.

A census taken in 1920 gave the total population of Old and New Greece as 5,536,375, including Thrace. An estimate which allows, on the one hand, for the subsequent loss of territory and for the transfer of the Moslem inhabitants of Greece to Turkey, and, on the other hand, for the influx of some 1,400,000 refugees from Turkey after the war in Asia Minor, would place the population in 1925 in the neighbourhood of 6,200,000.

The various racial migrations which have been brought about by the wars from 1912 onwards, whether voluntary or compulsory, involving the transfers, in either direction, of nearly 2,500,000 Greeks, Bulgarians and Turks, have had the result of introducing homogeneity in the regions affected, where before there was great diversity. Thus the proportion of Greeks in the population of Macedonia and Western Thrace, which stood at 43 and 36% respectively before the Balkan Wars, is, in 1925, 88 and 62%. (L. G. R.)

I. POLITICAL HISTORY

In Jan. 1910 the Military League had summoned Veniselos from Crete as their political adviser, and he had arranged for the election of a National Assembly. But the obstruction of the party leaders soon obliged him to take the premiership himself and to appeal once more to the electorate. When the second revisionary National Assembly met on Jan. 22 1911, he took office at the head of an overwhelming majority. During the following 18 months the constitution was revised, internal administration was thoroughly overhauled, army and navy were remodelled and trained under French and British missions, and the Macedonian feud was forgotten.

The Balkan Wars.—A treaty was signed with Bulgaria (May 1912) who had already signed a treaty with Serbia for the partition of Macedonia, and in Oct., the first Balkan War broke out. Montenegro declared war on Turkey, Oct. 8; Turkey declared war on Bulgaria and Serbia, Oct. 17, but offered Greece the island of Crete and other concessions to remain neutral. Veniselos however realised the supreme importance of including Greece in the new grouping. The long-excluded Cretan deputies were admitted to the Greek Chamber and Greece declared war on Turkey on Oct. 18 1912.

The Balkan allies gained rapid success. The Greek Army cleared Macedonia and occupied Salonika (Nov. 9); the fleet blockaded the Dardanelles. Greece refused to sign the armistice obtained from the other allies (Dec. 3) but joined the conference which met a fortnight later in London. The allies demanded from Turkey the surrender of all the territory their armies actually held in Europe together with the fortresses invested. The seizure of power by the " Young Turkish " party at Constantinople prevented the acceptance of these terms, and hostilities were re-opened on Feb. 3 1913. But after Adrianople had surrendered to Bulgarians and Serbs, Scutari to the Montenegrins, and Janina to the Greeks under Prince Constantine—who 12 days later (March 18) became King on the assassination of his father George I. at Salonika—Turkey by the Treaty of London (May 30) signed away collectively to the Balkan allies all her territory in Europe west of a line drawn from Midia on the Black Sea to Enos on the Aegean Sea, leaving the Powers to settle the problems of Albania and the Aegean Islands.

Second Balkan War.—The erection of an independent Kingdom of Albania, by excluding Serbia from the Adriatic, rendered inevitable a quarrel between the allies. Greece, alarmed at the menacing attitude of Bulgaria, had in June signed a defensive alliance with Serbia, and when Bulgaria attacked without warning (June 30) she was heavily defeated, and after the intervention of Rumania was compelled to sign the Treaty of Bucharest (Aug. 10 1913) which excluded her from the Aegean port of Kavalla and carried the frontier of Greek Macedonia eastwards to the river Mesta and northwards to Doiran and Florina. The course of events had thus compelled Veniselos to substitute a policy of balance of power for that of a Balkan League.

The Aegean Islands.—The Powers assigned to Greece (Conference of London, Feb. 1914) all the islands of the Aegean actually occupied by the Greek fleet during the war, with the exception of Tenedos and Imbros and of the islands of the Dodecanese which Italy had occupied in 1912 as security for the Turkish fulfilment of the Treaty of Lausanne (Oct. 18 1912) pledging her good faith that her occupation should be conditional and temporary. After the World War, Veniselos negotiated an agreement with Signor Tittoni (July 29 1919) by which all these islands were to revert to Greece unconditionally, the cession of Rhodes alone being made contingent on a plebiscite to be held within five years of England's cession of Cyprus. This agreement was recognised by the Supreme Council, the time limit within which the plebiscite was to be held being extended to 15 years, on the signature of the Treaty of Sèvres (Aug. 10 1920) in accordance with which Tenedos, Imbros and Lemnos, which had been occupied during the War by the British fleet, were handed over to the Greek authorities on June 25 1921. The Tittoni agreement was repudiated by Italy, who remained in occupation of the Dodecanese, after the fall of Veniselos and the non-ratification of the Treaty of Sèvres. Turkey closed the Balkan war with Greece by a provisional agreement (Treaty of Athens, Nov. 13 1913) but refused to accept the decision of the Powers of Feb. 1914; consequently the *de jure* possession of the islands remained in suspense until the Treaty of Lausanne (July 24 1923) whereby Turkey renounced in favour of Italy all rights over the Dodecanese, and recognised Greek sovereignty over the remaining islands as conferred by the Conference of London, subject to certain provisions for their demilitarisation, and with the exception of Imbros and Tenedos, which were retroceded to Turkey on condition that they should enjoy full local autonomy.

The World War.—Greece definitely annexed Crete and thus emerged from the Balkan Wars with a very large acquisition of territory in Epirus, Macedonia, Crete and the Aegean Islands, with a total population of over 1,800,000, or almost as much as that of " Old Greece." Turkey's refusal to recognise the ru
of the London Conference was accompanied by a boycot
Greek shipping and an organised persecution of the Greek
Asia Minor. But her evident intention of re-opening hostil
with Greece was anticipated by the outbreak of the World
The attitude of the Greek Govt. as stated by Veniselos was n
in doubt. Not only did her interests and tradition bind he
support Great Britain and France; she was bound to Serbia
her defensive alliance, the purpose of which would best be se
if Greece stood by to prevent Bulgaria from making any ho
move and to guard Serbian communications with the Aeg
King Constantine on the other hand naturally inclined to
many for family reasons, and believed in her victory; bu
never found the courage to declare openly his intention to re
neutral, preferring to temporise.

In Feb. 1915, when England definitely required Greek
for attacking the Dardanelles, the proposals of Veniselos
specific Greek forces to co-operate with the British fleet
unanimously approved by his own majority in the Cham
and by a Crown Council of all the political leaders in the k
dom. King Constantine however dismissed Veniselos and
solved the Chamber (April 10 1915). The new premier Goun
co-operated with the German propaganda in Athens to repre
Veniselos as inspired only by love of war and hatred of the K
King Constantine was thus brought into party politics as a
sonal opponent of Veniselos and leader of the " pro-Germa
policy of neutrality. In mid-June the electors nevertheless
turned the Liberal (Veniselist) party with a majority. But
Veniselos, after a delay excused by the King's illness, at
returned to office (Aug. 22), his efforts to immobilise Bulg
by threatening Greek action were useless, because Germany
already been secretly informed that Greek neutrality woul
guaranteed by King Constantine even in the event of a
garian attack on Serbia. Bulgaria mobilised on Sept. 19 1
and King Constantine allowed his Prime Minister to ord
counter-mobilisation, and even to suggest to England and Fr
that they might reinforce the Greco-Serbian co-operation
some of their own troops, a suggestion which led to the A
landing at Salonika. But as soon as Veniselos, on the eve of
Bulgarian attack, explained once more his well-known polic
defending Serbia and received a vote of confidence, he
abruptly dismissed, and M. Zaimes was put up (Oct. 5) to exp
that the Greco-Serbian Treaty had " a purely Balkan cha
ter." The Chamber was again dissolved and elections hel
December. The Liberals abstained from the polls, as a pro
against this second and unconstitutional dissolution, and a
ernment was formed under M. Skouloudes (Nov. 6), who decl
" very benevolent neutrality " towards the Entente.

From this time forward the King began not only to expect
eagerly to desire a German victory. The violence of his parti
was aggravated when the " Three Protecting Powers," Brit
France and Russia, demanded certain administrative cha
which might prevent any connivance between the Govt.
the German espionage (June 21 1916). The Greek Army, w
owing to the known sentiments of its general staff threate
or at least inconvenienced, the Allied base at Salonika, wa
last demobilised; whereupon the Bulgarians invaded Maced
and seized Kavalla. Meanwhile King Constantine would f
time to time change his Premier (Zaimes, June 23; Kalog
poulos, Sept. 16; Lambros, Oct. 9; Zaimes, May 3 1917) and
the French or British minister to suggest terms on which it m
suit him to abandon his " neutrality." When in Aug. Ruma
joined the Allies and the King still refused to move, Venis
seceded to Salonika (Sept. 25 1916) with Gen. Dankles and A
Condouriotes, set up a Provisional Government and out of
the kingdom which declared its allegiance to the Triumvi
began to organise a state militant. The Allies refused t
official recognition to the Salonika Govt., although Venis
troops were already fighting for them. At Athens the Fre
admiral suggested that King Constantine might surrender s
of his war material. The King was understood to consent;
when French and British marines landed to take delivery t

re shot down by Greek troops from prepared positions (Dec.
916).

The Allies now broke off relations with the King, but, owing
the hesitations of Russia and Italy, did not demand his abdi-
ion till June 1917. He retired to Switzerland (June 12) and
second son Alexander was put on the throne. Veniselos
urned to Athens as Prime Minister of a nominally united
eece (June 26), recalled the Chamber which had been uncon-
utionally dissolved in Nov. 1915 and formally declared war
inst Germany, Turkey and Bulgaria (June 29). By April
8, the Greek Army had been mobilised and re-equipped. In
y 250,000 Greek troops shared in the Macedonian offensive
ich culminated in the capitulation of Bulgaria (Sept. 30 1918).

Treaty of Sèvres and Fall of Veniselos.—At the Peace Confer-
e (Paris, Jan. 1919) Veniselos' presentation of the Greek
ims was remarkably successful. As affecting Bulgaria these
re embodied in the Treaty of Neuilly, to which was annexed a
eco-Bulgarian convention for the protection of racial minori-
s, etc. (Nov. 27 1919). Bulgaria was cut off from the Aegean,
Allies undertaking to ensure her an "economic outlet." This
blem has not hitherto been solved, as it was found impossible
Lausanne (Jan. 1923), even with the guarantee of the League
Nations, to devise any scheme, other than a territorial cor-
lor, acceptable to Bulgaria. The Treaty of Sèvres (Aug. 10
20) assigned to Greece the greater part of Thrace, and a man-
te, based on Greece's interest in the Greek population of Asia
inor. It also assigned to her the basin and hinterland of
yrna under a strictly controlled régime. Greek troops had
ded at Smyrna at the request of the Supreme Council on
ay 15 1919.

Unfortunately during these negotiations Veniselos had lost
uch with his people, and the Govt. at Athens had proven incom-
tent and corrupted. The resulting discontents were exploited
Constantine's agents. Not the Greek peasants only but many
the urban population were innately averse to Veniselos'
th-century ideas. In Aug. 1920 Veniselos returned to Athens
ed out, and angrily refused any electioneering compromise
th the 16 leaders of opposition. Then King Alexander, playing
th a pet monkey, was bitten. He died of blood-poisoning
ct. 25) and his younger brother Prince Paul having refused
e Government's offer of the throne, the restoration of King
nstantine became the real issue at the general election. On
v. 14 1920 Veniselos was heavily defeated at the polls. He
signed, and with many of his ministers and officials left the
untry. A government was formed by the aged Demetrius
lli which entrusted the Regency to the Dowager Queen Olga.
Aiter the formality of a plebiscite King Constantine returned
Athens (Dec. 19 1920). The Allied Powers refused to recog-
se him officially, withdrew their financial assistance, and agreed
reconsider the Treaty of Sèvres, which though signed had not
en ratified and had already been repudiated by the Turkish
ationalists. The withdrawal of their support was serious. The
mistice concluded with Turkey (Oct. 30 1918) had made very
complete provision for the disarmament of the Turkish forces
d it was partly in order to restore order in Asia Minor and
otect the Christian populations that Greek forces had been
thorised to land at Smyrna. But the Supreme Council, al-
ough it had finally (July 1920) asked the Greek troops, in Mr.
oyd George's words, "to clear up the whole neighbourhood
tween Smyrna and the Dardanelles," a task successfully
complished in 10 days, had set very definite limits to the Greek
my of occupation: and Mustafa Kemal had had time to organise
ormidable force. Greece was isolated; France and Italy both,
ertly or covertly, supported Turkey, and Great Britain de-
ned to embark on expensive Eastern adventures.

Greco-Turkish War.—Yet the new premier M. Kalogeropoulos
eb. 7 1921) and his successor M. Gounaris (April 7) rejected
e moderate proposals of a Conference of the Three Powers
ritain, France and Italy) which met in London (Feb. 21) to
onsider the Treaty of Sèvres; and instead actually ordered
m London an offensive (March 24) against the Turkish Na-
nalist positions, which after seizing Afiun Qarahisar and Eskishehr, was disastrously defeated (April 5) with 4,000 killed and wounded. On June 11 (anniversary of the fall of Constantinople in 1453) King Constantine left for Smyrna hailed by the government press as emperor designate of Constantinople and commander of the Anglo-Greek forces in the Near East. On June 19 the Allied Powers again offered "their friendly services to prevent the reopening of hostilties," but the offer was magniloquently rejected. The Greek forces opened their new offensive in July. A month later they were within 60 m. of Angora. But in August they were disastrously defeated on the river Sakkaria with very heavy losses. On Sept. 29 1921 King Constantine returned to Athens. On Oct. 16 Gounaris and his foreign minister Baltazzi, after receiving a vote of confidence in the Chamber, left for London and at last placed the interests of Greece without any reserve in the hands of Lord Curzon. Meanwhile the French "Franklin-Bouillon" agreement with Kemal had been signed at Angora (Oct. 20 1921); and Lord Curzon's ability to make peace was limited by the difficulty of coming to a preliminary agreement with France and Italy. Gounaris thus abandoned all Greek interests vested in the Treaty of Sèvres. He also gave up all claim to the balance of credits guaranteed to Greece by the Allies during the War and received in return permission to raise a loan on the open market if he could (agreement with Sir R. Horne, Dec. 21 1921). At Athens this was represented as a financial triumph, and thus arose considerable outcry in British Press and Parliament to the effect that England was secretly financing the Greek Army. Meanwhile the true situation was hidden from the Greek people; the persecution of Liberal deputies and journalists continued. Nor were the Liberals consulted when Gounaris on returning to Athens (March 10 1922) was compelled to reform his government. When the Near East Conference met in Paris, proposals for an armistice and the evacuation of Asia Minor by the Greek Army were transmitted to Athens and the two Turkish governments of Constantinople and Angora (March 26). The real Turkish power, that of Angora, explained away the apparent acceptance of these terms at Constantinople by making it plain that Turkey would accept only the immediate evacuation of Asia Minor.

A few days before the Conference Gounaris had privately addressed to Lord Curzon a desperate appeal for help and confession of imminent disaster. On May 11, after vainly following Mr. Lloyd George to Genoa, he resigned and joined M. Stratos in a coalition under the premiership of M. Protopapadakes, who had previously as Minister of Finance raised a forced internal loan by cutting in half all the bank notes in circulation. The first act of the new Govt. was to remove the commander-in-chief, Gen. Papoulas, who had privately advocated strengthening the front by the reinstatement of Veniselist officers previously removed, and to appoint in his stead Gen. Hadjanestes. In July the Govt. had the independence of Ionia proclaimed by the high commissioner of Smyrna, M. Sterghiades. They also issued a report that the Allies would shortly allow the Greek Army to occupy Constantinople; while Gen. Hadjanestes, a figure of notorious eccentricity, completed the demoralisation of the front and actually transferred large bodies of troops from Asia Minor to Thrace. The Turks attacked on Aug. 26 and entered Smyrna on Sept. 9 1922; five days later the whole city, with the exception of the Turkish quarter, was burned to the ground.

Revolution of Chios.—The Govt. resigned on Sept. 8, after ordering the demobilisation of the troops who were leaving Smyrna. But the attempt to scatter the remnants of the army as they were evacuated from Asia Minor failed. Many units landed on the island of Chios; and there a revolution headed by Col. Plasteras broke out on Sept. 26. King Constantine left the country and died in the following Jan. at Palermo. Eight of his principal ministers and advisers indicted by a special Commission of Enquiry were tried before an extraordinary court martial of 11 officers. Six of the accused (Gounaris, Stratos, Baltazzi, Theotokes, Protopapadakes and Hadjanestes) were shot immediately after the verdict (Nov. 28 1922). The executions shocked Europe. The British Minister, Mr. Lindley, who had refused to take the responsibility of guaranteeing that the accused, if reprieved, should never again take part in politics, left Athens. But they had a salutary effect on the Greek Army. Thousands of deserters returned to the colours, and a small but efficient army, reformed on the Thracian frontier under the command of Gen. Pangalos, greatly strengthened the hands of the Greek representative (Veniselos, who had consented to represent his country abroad) and of all the Allies at the second Conference of Lausanne which finally succeeded in signing peace with the Turks on July 24 1923.

Refugees and Minorities.—Meanwhile the Revolutionary Govt., after proclaiming an amnesty for all political offences (Jan. 22 1923), was confronted with the problem of the million destitute refugees expelled from Asia Minor. For some months the settlement of the refugees on a productive basis was organised with the help of American charitable societies; later the Greek authorities had to depend entirely on their own resources until a loan was raised (Dec. 1924) the administration of which was guaranteed by the League of Nations. In 18 months the Refugee Settlement Commission of the League of Nations had settled more than half a million refugees in new villages and urban districts throughout Greece. This settlement increased the homogeneity of population on the Greek frontiers, where the problem of alien minorities had already been reduced by a system of exchanging populations, embodied in the Greco-Bulgarian Convention (1919) for the voluntary emigration of minorities and the Greco-Turkish Convention (Jan. 30 1923) for the compulsory exchange of Moslem and Greek-orthodox minorities. These agreements (together with the Turco-Bulgarian agreement of 1913) completed and regularised a series of migratory movements which had begun with the Balkan Wars and had transformed the populations of Thrace and Macedonia. Thrace east of the Maritsa is now completely Turkish, Western Thrace predominantly Greek; and in Sept. 1925, the League of Nations Refugee Settlement Commission reported that Greek Macedonia was then "crowded with an active and industrious population, of which more than 90% were Greeks by race and sentiment" (*see* REFUGEES).

The Corfu Incident.—On Aug. 27 1923, the murder of the Italian member of the Greco-Albanian Frontier Commission led to the Italian bombardment of Corfu. Greece appealed to the League of Nations through whose agency the dispute was ultimately settled (*see* LEAGUE OF NATIONS). Greece's correct and conciliatory attitude in this unfortunate dispute did her great credit.

Return of Veniselos.—At home the revolutionary Govt., led by Cols. Gonatas and Plasteras with M. Alexandres as Foreign Minister, made genuine attempts to return to constitutional government. They failed however to form a moderate centre party (Sept. 1923); and a month later the extreme Royalists, under Gen. Metaxas, attempted to raise a counter revolution, which was easily suppressed. There was evidence that Gen. Metaxas had been in communication with King George II. The Republicans thus received a tremendous impetus, and though at the elections (Dec. 16 1923), from which the Royalists abstained, they were defeated, they had secured the support of the army and the navy, under the influence of Gen. Pangalos and Capt. Hadjikyriakos, whose pressure was so energetic that the Govt. to avoid disorder requested the King to absent himself during the meeting of the National Assembly which was to decide the future of the Throne. On Dec. 18 1923 the King and Queen left for Rumania. Adm. Condouriotes was appointed Regent and Veniselos was invited to return to Greece. In view of the apparent unanimity of the appeal he found it impossible longer to refuse. He returned (Jan. 4 1924) only, he was careful to announce, temporarily, in order to "put an end to civil war," and proposed to solve the constitutional problem by an immediate plebiscite. The Revolutionary Committee resigned and Col. Plasteras retired into private life.

Establishment of a Republic.—A week after his arrival Veniselos unwillingly accepted the premiership. He proposed (Jan. 23) that a plebiscite should be held in two months' time, under the supervision of committees representing every party, to decide whether a republic was desirable, and if not who should be king. The decision was to be followed by a general election held under a system of proportional representation. He found himself opposed however by the extreme Republicans under M. Papanastasiou who insisted on the immediate expulsion of the dynasty and establishment of a republic by a vote of the Assembly. Veniselos resigned the premiership (Feb. 4) to M. Kafantares who also favoured a plebiscite. He succeeded (Feb. 27) in defeating the Republican motions in the Chamber and was proceeding to
negotiate for a joint programme with the Royalists when
Officers League was reformed and demanded from Regent
Premier that a republic should be set up without more ado.
Kafantares resigned, Veniselos left Greece (March 10) an
government was formed by M. Papanastasiou, who propose
settle the fate of the throne by a resolution of the Chambe
be ratified by a subsequent plebiscite. After the King had refu
a very generous offer if he would abdicate voluntarily, there
no difficulty in getting the necessary vote. The republic
proclaimed on March 25 1924. The plebiscite, the arrangem
for which were accepted by the Royalists, was held on Apri
when 758,742 voted for the republic and 325,322 for a monar
The republic under the provisional presidency of Adm. C
douriotes was recognised on April 23 by England, who had resu
diplomatic relations on Jan. 16.

The Govt. of M. Papanastasiou was strengthened by
inclusion of Gen. Pangalos, Col. Kondyles and Adm. Hadji
riakos; but the two last-named officers soon left it again and
Papanastasiou resigned, and was succeeded by M. Sofoules
July 19, after a violent attack on the Minister for War, G
Pangalos, by M. Mihalakopoulos who himself formed a gove
ment on Oct. 7.

The Unratified Protocol.—At the end of July 1924, Bulgarian ko
tadjis captured on Greek territory at Tarlis were shot down by t
escort, and a month later a Commission of Inquiry appointed by
League of Nations censured the local authorities though it exoner
the Greek Govt.; a satisfactory feature was that the report
signed by the Greek member of the commission. On Sept. 29
Bulgarian and Greek delegates (Col. Kalfoff and M. Politis) mee
at Geneva signed a protocol providing that each Power should
point as its official advisers for carrying out the treaty protect
the interests of minorities Col. Corfe (British) and Major de Roo
(Belgian), who were already at work on the frontier as members
the existing mixed commission for the exchange of populations
pointed under the Greco-Bulgarian convention of 1919. T
authority would be a protocol embodying provisions containe
the Treaty of Neuilly and repeated in an annexe to the Treaty
Sèvres. Unfortunately this sincere and generous movement was
garded at Belgrade as an arbitrary recognition of the existence
"Bulgar" minorities in Greece which might lead Bulgaria to cl
similar privileges for "Bulgar" minorities in Serbia. Serbian
noyance and Greek suspicion were quickened by exagger
rejoicing in the Bulgarian press. On Nov. 27 Serbia denour
the Alliance with Greece and this undoubtedly determined Gr
repudiation of M. Politis. On Feb. 3 1925, the Greek Cham
refused to ratify the protocol and on March 14 it fell to Ve
selos to announce and defend this refusal before the Council of
League.

Negotiations with Serbia.—On April 27 1925 negotiations for
newal of the Greco-Serbian alliance were opened at Belgrade
soon broke down over the preliminary demands of Serbia. Ser
demanded the control and exploitation of the railway from Ghev
to Salonika; an extension of the Serbian zone on the harbour
Salonika; and a recognition that the Slavs of Macedonia were
"Bulgars" but "Serbs." This last demand was referred
Greece to the League of Nations. With regard to the railway
she offered to rebuild and reorganise the line or to appoint a
manent League of Nations official to arbitrate on all Serbian c
plaints but objected to any such cession of rights as would be
only a diminution of sovereignty but a continual source of fricti
The negotiations were broken off on June 1, and a subsequent
posal that the line should be worked by a French company (Oct.
was not more successful. With regard to the larger question of
Alliance, which remained in suspense, there was a possibility th
both Powers having disclaimed any territorial ambitions, nego
tions might be re-opened (Jan. 1926) for the conclusion of a Balk
security pact analogous to that of Locarno.

The Patriarchate.—At the Conference of Lausanne the Turks
consented to the maintenance of the Oecumenical Patriarch at
Phanar provided he exercised no civil or administrative pow
But on Jan. 30 1925 the new Oecumenical Patriarch was expe
from Constantinople by the Turks, who contended that he was
an "inhabitant of Constantinople" and that accordingly he was
exempted by the Treaty of Lausanne from the provisions of
Convention for the Exchange of Populations. In any case the Gre
had put themselves in the wrong by ignoring the usual formaliti
election and failing to obtain Turkish consent to his candidatu
The Council of the League of Nations referred the dispute to
Hague Court (March 14); but meanwhile Greece and Tur
arrived at a settlement, Greece persuading the expelled Patriarch
resign.

Gen. Pangalos Seizes Government.—Meanwhile the Natio
Assembly had not yet succeeded in voting the new constituti

ad there were numerous complaints of peculation and admin- trative inefficiency. On June 16 M. Mihalakopoulos reformed is government but 10 days later, confronted by an ultimatum om Gen. Pangalos and Adml. Hadjikyriakos, he resigned. Gen. angalos formed a government (June 26) including Adml. Hadji- yriakos, M. Kofinas and, later, M. Rentes (July 2), an experi- nced diplomatist, and after receiving a vote of confidence dis- olved the Assembly. The new constitution, issued by procla- nation on Sept. 30, provides for a president to be elected for a erm of five years and a Senate of 150 members, 100 to be elected y the parliamentary franchise, 30 by various guilds and cor- orations and 20 by Chamber and Senate. Gen. Pangalos romised that it should be submitted for ratification after elec- ons to be held in the new year. A proposal to court martial M. Papanastasiou for issuing a democratic manifesto was can- elled (Oct. 5) but Gen. Plasteras was expelled from Athens Oct. 24). Two officials were publicly hanged for embezzlement.

On Oct. 19 there occurred a fresh frontier "incident" with ulgaria, in the course of which the latter appealed to the League f Nations (*see* League of Nations: *Work of the First Six ears*). The commission ordered Greece to pay damages and ound she had violated the Covenant by occupying Bulgarian erritory with her troops. The commission also made various ecommendations for avoiding frontier incidents (including a ystem of frontier guards under neutral officers), and for com- leting without friction the convention for the Exchange of Populations. The undoubted success of the League was obscured n Athens by an inevitable comparison with the Corfu affair, ut the decision of the Council in accordance with the report was ccepted by the Greek Govt. on Dec. 15.

Meanwhile Gen. Pangalos was making strenuous efforts to uppress political rancour at home. On Nov. 24 at a conference with the party leaders he received assurances that the constitu- ional question would not be raised at the elections in March nd on this understanding the election of a senate was fixed for an. 10, and two Royalists, M. L. Roufos and M. Sehiotes, entered he Government. Apparently however it was too much to expect olitical leaders not to talk politics. On Jan. 3 1926 and in sub- equent proclamations Gen. Pangalos announced that the sena- orial and parliamentary elections would be indefinitely post- oned and that his Government had decided to concentrate all xecutive and administrative powers in its own hands; with the declared aims of economy and internal order and the forcible econciliation of contending factions the Ministries of National Economy and Public Assistance were abolished, the permanence of the civil service was suspended and the Press was forbidden o publish any articles written by MM. Kafantares, Papanas- asiou and Mihalakopoulos. Adml. Hadjikyriakos and M. Sehi- otes immediately resigned. At the Ministry of Finance M. Tan- alides, replacing M. Kofinas who had gone on a debt-funding mission to Washington, issued a forced loan similar to that of 1922 from which foreigners were not to be exempted (Jan. 23). All these measures were received by the people with the fatigue and listlessness which were becoming almost a substitute for political stability. Indeed while the agreeable M. Roufos re- mained at the Foreign Office to develop the improving relations with Serbia, Italy and Albania there was a prospect that Greece might at last enjoy a period of tranquillity and good government. The dictatorship of Gen. Pangalos had the merits as well as the defects of a fire-eating common sense, and it had the advantage of not being disguised in any pretentious ideology. (J. N. M.*)

The Country's Defence

The normal duration of military service, which is compulsory for all Greek citizens, is two years in the active army, 11 in the reserve and eight in the territorial army. Men are called up at the age of 21, and are liable for service until 51. Territorials are only called up in case of invasion or threat of invasion, and are only called up for training twice in the fourth and eighth year for a fortnight. The peace-time strength of the army is 12 infantry divisions, 1 cavalry division and a certain number of units unattached. The total personnel in 1924–5 was 66,484. The Greek Navy consists of 5 old battleships, 1 armoured and 1 protected cruiser dating from before the World War, 11 destroyers and 36 smaller units, including 2 submarines. (X.)

II. ECONOMIC AND FINANCIAL HISTORY

Pre-War Position.—The economic situation of Greece during the early years of the present century, up to the outbreak of the Balkan War in 1912, was marked by a steady if moderate progress. Industrial enterprises for local purposes were established in considerable number. Communications by road and railway were extended, and large additions were made to the mercantile marine. The premium on gold gradually declined, and finally disappeared in 1909. By the Valaoritis law of 1910, providing for the automatic issue and withdrawal of notes against gold or foreign exchange, the currency was definitely stabilised at par on the gold exchange system, to the great advantage of the general economy and the credit of the country.

The state of the public finances, though less satisfactory, also showed signs of improvement at the latter end of the period. A series of deficits from 1907 to 1909 had to be met out of a portion of the proceeds of a new foreign loan raised for this and other purposes in 1910. At the same time, a programme of fresh taxation was introduced, including income tax and succession duties, with the result that the accounts up to 1912 showed a substantial surplus of revenue over expenditure. The varying interest on the old gold loans, payable out of surplus revenues in the hands of the International Financial Commission, marked a sensible upward progress.

The Balkan Wars of 1912 and 1913 threw a considerable strain on the resources and the finances of Greece, which was, however, relieved in some measure by the material assistance rendered by Greeks abroad. Immediate war expenses were defrayed chiefly out of the balance of the 1910 loan and the proceeds of various provisional loans, which were liquidated by means of a new consolidated loan issued in 1914, and taken up for the greater part in Paris and London. This loan was secured on the revenues assigned to the International Financial Commission, an institution which, though regarded as an encroachment on the sovereign rights of the country, has been found useful on repeated occasions as a means of providing security for fresh loans. The economic strength of Greece was greatly enhanced by the acquisition of territories of both actual and potential value, including the important port of Salonika, the rich tobacco-growing districts of Drama and Kavalla and extensive areas in Macedonia capable of productive development.

The World War.—After the outbreak of the World War, and during the period of neutrality of Greece, which lasted from 1914 until 1917, there was a considerable accumulation of private wealth in the form of foreign balances, but the country suffered severely from internal conflicts, from the economic blockade of Old Greece in 1916–7 and from the prolonged mobilisation and war preparations. Noteworthy economic events during this period were: the law of 1915 facilitating the formation of co-operative societies; the connection, in 1916, of the railway system of Greece with those of Europe; and the agrarian legislation of 1917, which provided for the expropriation of large estates in favour of the peasants, and at the same time prohibited the alienation or mortgage of the peasants' holdings and their subdivision at death.

The entry of Greece into the War in 1917 involved a large increase in military and naval expenditure. Fresh taxation was imposed, including a tax on War profits, and a certain sum was raised by an internal loan and by the issue of National Defence bills. But the bulk of the funds required was provided by advances in kind from the Allied Powers and by credits opened by the latter for expenditure in Greece, against which payments were effected in notes by the Greek Government. These credits were treated as cover for the note issue. The very considerable expansion in the paper currency which resulted from these arrangements did not cause at first too heavy a demand for exchange, for the factors which contributed to strengthen the foreign balances during the period of neutrality continued to operate until the end of the War.

With the close of the War, however, and the suppression of restrictions on trade, the accumulated purchasing power of the country made itself felt in a large demand for foreign goods. Large purchases of Greek and other securities were made in foreign markets, and the depreciating currencies of Europe offered an attractive field for the speculator. The resultant pressure on the exchange funds of the note-issue was so great that before the end of 1919 the available reserves were exhausted, the exchanges began to fall away from the gold parity, and the Valaoritis law became a dead letter. In the course of 1920 a portion of the Allied credits was realised, but this was quickly absorbed by purchases of supplies, and the excess of imports reached unprecedented proportions.

Effects of the Greco-Turkish War.—At the same time, the Govt. found itself involved in fresh liabilities in connection with the military operations in Asia Minor. To raise the considerable funds required, recourse was had to a large internal lottery loan, to issues of National Defence bills, to loans from the National Bank and, finally, to inflationary issues of paper money. The fall in the exchanges was accelerated by the withdrawal of financial support and credits by the Allies on the return of King Constantine in 1920. By the end of that year the drachma had lost 60% of its gold value. This depreciation of the currency reacted unfavourably on the budget, while the prosecution of the Asia Minor campaign entailed ever-increasing expenditure. In 1921 and 1922 issues of paper money and National Defence bills were effected on a large scale, without authority from the International Financial Commission taxes were raised and a forced loan was extracted from note-holders by compelling them to surrender one-half of each note in exchange for a government bond. The disaster in Asia Minor in 1922 reduced the finances and credit of the country to the lowest ebb, and by the end of the year its securities were quoted on the international markets at prices yielding 20% to the investor, while the drachma had lost 94% of its gold value. This collapse of the monetary unit, with the concomitant rise in the price-level, profoundly disturbed economic conditions throughout the country, and caused serious losses among particular sections of the community. The bulk of the public debt being on a gold basis, the real charge of its service on the state finances was not greatly reduced by the depreciation.

Refugee Settlement.—The influx from Asia Minor and Thrace of a vast number of destitute refugees threw a fresh burden on the resources of the country, and enlisted the sympathy and assistance of foreign countries, especially of England and America. Under the auspices of the League of Nations an independent refugee settlement commission was set up in 1923, for the establishment of the refugees, and a refugee loan was issued in 1924, in London, New York and Athens, guaranteed by revenues assigned to the International Financial Commission. Meanwhile, the Govt. made strenuous efforts to put its finances in order. Considerable fresh taxation was imposed in 1923, including a capital levy to be spread over five years, which has given very mediocre results. The floating debt was largely increased in 1923 and 1924. A fresh uncovered issue of paper money was made in 1923, and at the same time a law was passed authorising further issues against cover in funds abroad. The exchange, after violent fluctuations, settled down in 1924 to about one-tenth of the gold parity. By 1925 the public finances had so far recovered that the Govt. was able to allocate special revenues to the reduction of the floating debt, and to present a balanced budget. But this equilibrium was afterwards disturbed by fresh expenditure and by a renewed fall in the exchanges, due to an inflationary banking policy and a maladministration of the foreign exchange fund created by the law of 1923. At the end of 1925 the drachma had again fallen back to one-fifteenth of its gold parity.

Notwithstanding the instability of the political régime, of the public finances and of the monetary policy, the country as a whole showed remarkable powers of recuperation after a period of 10 years of war ending in a great national disaster. The refugee population tended to become an asset instead of a burden. The refugees settled in Macedonia, extended the cultivated area and increased the production of crops, while large numbers found employment in industrial and other occupations. The expropriation of agricultural properties for the benefit of refugee an other peasants was accelerated, on terms very unfavourable t the owners, by special legislation in 1923 and 1924. The mercantile marine, which had been reduced by nearly two-third during the War by sales and losses through enemy action, wa restored to its original strength. Exports expanded slowly, bu the growth of imports bore witness (apart from the portio attributable to foreign loans) to the extent of the country's additional resources in the form of shipping and other profits, o remittances from emigrants and of investments that wer held abroad.

The greatly increased burden of public debt was mitigated b the fact that the larger part of it was held by her own nationals Nascent local industries, hampered during the War for lack o fuel, took a fresh upward stride, stimulated in some degree b high tariffs and other protective measures, and by the influx o refugee labour. The extension of building operations and othe forms of economic activity afforded evidence of increased prosperity, but an exact measure of real progress could not be ascertained while inflation continued. Railways, roads, ports an urban services generally were still in a backward state. At th end of 1925, however, numerous projects were in contemplatio or in course of execution, with the aid of foreign capital, fo extensive improvements in these directions and for the furthe development of local resources.

Statistical Comparisons.—The following statistical table summarises the changes in some of the salient economic and financia features of Greece over an interval of rather more than ten years *i.e.*, 1914 to 1924.

	1914	Present day	
Area, square miles	46,000	1925	49,200
Population	4,800,000	1925	6,200,000
Production of cereals, tons	847,000	1925	871,000
Production of tobacco, tons	25,000	1925	66,000
Production, currants, tons	158,000	1925	133,000
Production of emery, tons	16,000	1925	20,000
Production of lignite, tons	20,000	1925	111,000
Exports, drachmas	178,500,000	1925	4,320,000,000[1]
Imports, drachmas	318,800,000	1925	9,834,000,000[1]
Joint stock companies	68	1925	325
Companies, capital of, drachmas	363,000,000	1925	2,190,000,000[1]
Co-operative societies	5	1925	3,655
Letters carried	29,810,000	1924	73,403,000
Telegrams despatched	1,968,000	1924	5,502,000
Telegraph lines, miles	5,735	1924	11,225
Railways open, miles	1,366	1925	1,689
Piraeus entries, steamships	3,809	1925	7,915
Piraeus entries, net tonnage	4,067,000	1925	5,044,000
Mercantile marine, steamships	474	1925	467
Mercantile marine, gross tonnage	830,000	1925	912,000
Bank deposits, drachmas	474,000,000	1925	5,755,000,000
Bank deposits, postal savings, drachmas	700,000	1925	93,500,000
Note circulation, drachmas	253,000,000	1925	5,339,000,000
Public debt, gold £	43,900,000	1925	77,800,000
Public debt, currency, drachmas	173,600,000	1925	7,918,000,000
Ordinary revenue, drachmas	207,700,000	1924-5	4,719,000,000
Athens cost of living, index no.	100	1925 Dec.	1,644
Exchange on London, drachmas per £.	25	1925 Dec.	378

[1] These figures must be considered in relation with the exchange.

G. R.)

REEK LITERATURE, ANCIENT (*see* 12.507).—Our knowl- ge of ancient Greek literature has been increased greatly since beginning of the century. In 1918 Sir Frederick Kenyon ew of 920 literary papyri: Professor Oldfather in 1923 counted 67. No entirely new authors have been discovered equal in portance to Bacchylides, Herondas and Timotheus, and no w treatise quite equal to Aristotle's *Constitution of Athens.*

The New Comedy.—Of Menander we have considerable frag- nts—found in 1907—from seven plays, ranging from 550 es to 88, and can form some opinion of at least three: *The itrepontes* (Appeal to Arbitration), with ten characters; *The rikeiromenê* (Girl with her Hair Cut), with eleven; and per- ps *The Samian Woman.* Again, we have part of the plot of *e Priestess.* A man's wife has left him (possibly for religious asons) and become a priestess; he does not know what she did th their son, and the priestess is unapproachable. His slave etends to be possessed by a demon, and so gets taken in to the iestess to be treated. He finds out that the boy is being reared their own by certain neighbours, and tells the father, who es straightway to claim his son. But these neighbours also ve a genuine son of their own, and by mistake the old gen- eman lights upon him. The boy decides that the old man is ad, and tells his foster brother, who, consequently, when his ther approaches him on the same subject, humours him as a natic. . . .

An opening like this shows how far we have travelled from e simple μῦθοι of the 5th century. We can see that Menander vented his plots, and invented them with an ingenuity and mplexity utterly beyond the conceptions of the great trage- ans. We can appreciate his exquisite style; colloquial, yet fined, subtle and witty and capable of much emotional power. is palely reflected in the *urbanitas* of Terence. Contempo- ries who were still under the spell of tragedy and the Old omedy could ask themselves "whether Menander copied life life Menander"; but on a modern reader he will not make an pression of realism. Lost or exposed children, recognitions, be- ayed maidens, captured cities and heroines sold into slavery, ithful or ingenious slaves, indulgent or cross parents, play a rger part on his stage than they ever did in real life.

Yet the general effect does give a vivid picture of Hellenistic thens. It is an easy-going and cultivated commercial society, eering as best it can, with much understanding and sympathy d humour, amid the shipwrecks of a tormented world. There e no villains, no cruelty; the women have character, the be- ayed maidens have generally been betrayed in the excitement of me wild religious festival, and the betrayer suffers torments of morse. Except in the exposing of children, a favourite motive Hellenistic fictions, Menander's moral outlook would com- are favourably with that of Molière, not to speak of Congreve.

Callimachus.—Callimachus too has become a reality and we an understand the immense influence he exercised upon the ugustan poets. We possess many fragments from his *Aitia r Origins*, one of them 80 lines long. Unfortunately nothing is omplete; but the fragments show a mastery of the Greek legiac couplet unknown before. The diction is rather precious. he style often reminds one of Ovid, romantic with a touch of elf-mockery, as though the poet felt the absurdity as well as the oveliness of the archaic legends which he collected with so much est. The Alexandrian courtier is shown in his "Lament on the eath of Arsinoe," his "Coma Berenices" (which we know in a atin version by Catullus) and other fragments. His gnomic oems are written in the assumed character of the ancient Hip- onax, but have none of that satirist's ferocity. One tells the tory of the prize for wisdom, which was offered first to Thales ut refused by him because Bias was wiser, and by Bias because omeone else was wiser and so on by all the wise men in turn. nother contains a contest for superiority between the laurel nd the olive, somewhat flat to modern taste.

Another acquisition is a large fragment of a *Life of Euripides* y Satyrus, a Peripatetic of the 3rd century B.C. It takes the orm of a dialogue; one of the characters is a woman; and the tone that of drawing room *belles lettres* rather than history. There is much gossip and anecdote, given for what it is worth; many quotations, and some good literary criticism, *e.g.*, the observation that Euripides wrote the "things that held the new comedy together, peripatetics, betrayed maidens, supposititious children, recognitions by rings and necklaces, etc." The fragment comes from Satyrus' *Lives* in six books, the last of which dealt with the lives of the tragedians. It is extremely interesting as a specimen of the new subject of study introduced by the disciples of Aristotle, personal biography of writers and *savants.* Satyrus seems to have been the chief authority for the anonymous *Life* which has come down to us with the MSS. of Euripides.

Lyric Poets.—Another new author of great interest is the Boeotian poetess Corinna, a contemporary and compatriot of Pindar, though curiously different from him. She stands right outside the sphere of Homeric influence. Her language is the colloquial Boeotian which she spoke, unaffected by literary tradition. Her themes, to judge from the two poems preserved, "The Contest of Kithaeron and Helicon," and "The Daughters of Asopus," are little more than local folklore. She cannot have been quite uneducated; her metre is too correct; but her work leaves the impression that Boeotian women in the 5th century, though they learnt *Mousikê*, did not know much literature. Unlike Sappho, she was a neither a bluestocking nor a genius.

Sappho herself is now represented by about 100 new fragments, but the papyri have been so crushed and broken that very little is continuous or intelligible. The most beautiful of the new songs is perhaps equal to the best known before and has the same poignancy. It begins: " . . . and simply I long to be dead. She left me sobbing, and said: 'Sappho, we have suffered terrible things. I swear, against my will I leave you.'" The exceptionally careful study of the whole material by Mr. Lobel has shown, first, that the papyri are very exact in reproducing dialect, and secondly that Sappho, except in poems modelled upon epic, wrote almost entirely in her native Lesbian. She stands between the rusticity of Corinna and the literary polish of Alcaeus.

Alcaeus also is represented by more than 100 new fragments, various in subject and metre, but seldom large enough to yield continuous sense. A comparison of Helen and Thetis, a few lines about Sisyphus' attempt to outwit Death, much about *dura navis, dura fugae mala, dura belli* confirm but do not greatly enrich the impression made by the previous fragments. There is style, spirit, vigour, variety and there must have been a mass of minute and intimate history. But we find perhaps more continuous beauty in the new fragment of Ibycus, passing in dreamy memory the great shadows of the Trojan War, or the short burst of lyrical hexameters in the style of Alcman.

Pindar, of whom we had before only *epinikia* (victory songs) is now represented by considerable fragments of paeans, *parthenia* (girl songs) and dithyrambs. The paeans show the same abrupt and tortured magnificence of style as the extant *epinikia;* the *parthenia*, as Dionysius of Halicarnassus (Demosth. 39) had remarked, are simpler, and show Pindar in a new mood. "Maidenly thoughts be mine and maidenly speech upon my tongue," says one fragment.

The Drama.—There is also much beauty in the lyrics of Euripides' *Hypsipyle*, one of which is a nurse's song to a baby, with the accompaniment of a rattle and a new effect in one of the scenes where a mother, raging against the nurse who has inadvertently caused the death of her child, is suddenly reduced to silent tears by the presence of the gentle sage, Amphiaraus. The quiet exit of Amphiaraus to his foreseen death, and the subtle indications of Hypsipyle's life-song devotion to Jason, the brief romance of her youth, are in Euripides' most characteristic style. The fragments of Sophocles' Satyr-Play, the *Ichneutae* (Trackers), have great charm. The infant Hermes has stolen the cattle of Apollo; the Satyrs go as detectives to track the thief, and hear underground the first music known on earth—the child playing on the lyre he has made. The remains of Sophocles' *Eurypylus* are very small, but show the great 5th century style.

Increase of Historical Knowledge.—If we turn from our direct gains in beautiful literature and try to estimate the new light thrown by recent discoveries on the history of Greek literature as a whole, the results are much larger. The excavations of Minoan Crete, though they have brought us no Greek text, make a difference to our understanding of the Homeric poems and of the whole heroic tradition. We see quite clearly now that the poems do not stand at the beginning of literature. There were ages of literature before them. Even their heroic subjects can in many cases be shown to have been already known in or before the 16th century B.C. Gems and frescoes of that date show us the siege of a city, like Troy; a man under the belly of a ram and clinging to its long wool, like Odysseus escaping from the Cyclops' cave; a scene in a deep glen, where a young man attacks an older man in a chariot, as Oedipus attacked Laius. This means that some of the main romantic motives used in Greek heroic poetry were already traditional then, attached to what names we know not. Again, the celebrated "Ring of Nestor" (*Jour. Hellenic Studies*, 1925) shows scenes of initiation and of the next life, ideas which have generally been considered post-Homeric and even for the most part post-classical. We see now that they were in existence before Homer as well as after; and the characteristic theology of Homer, with its avoidance of these ideas, shows itself to be not a thing of primeval simplicity, but a peculiar product of the "Heroic Age" (*i.e.*, the age of the destruction of Minoan civilisation by the Northern invaders). Again, while the excavations indicate pretty clearly that neither of the Homeric poems as a whole is "history," they also show that both are full of historic memories, in various degrees confused and fragmentary, and transmuted into the "heroic" mould.

Variety in Greek Literature.—But what we chiefly learn from the papyri is to appreciate the immense variety of Greek literature, especially in the Hellenistic Age. We have now specimens of three Satyr-Plays, instead of only the *Cyclops*. We have large masses of the New Comedy. We know something of the Alexandrian elegy and idyll, including bits of Euphorion as well as Callimachus. We discover the prevalence of poems in the style of different ancient writers: compositions in imitation of Hipponax, of Epicharmus, of Anacreon, of Alcman and letters professing to come from Hippocrates. We are reminded of the Delian Hymn with its claim to be by "Homer" himself.

Religious or ritual poetry is represented by several hymns and paeans connected with the temple of Apollo at Delphi or that of Asclepius at Epidaurus. The most curious is a paean to Asclepius, which occurs in four almost identical copies of different dates and places. It seems to have been a stock form, with places left open, so to speak, for the names of the particular city or individual wishing to perform the rite. More primitive worships, though in late form, are expressed in the Cretan Hymn to the Kouretes and the Eretrian Hymn to the Idaean Dactyls. The religious literature connected with Egyptian gods, such as Isis and Serapis, is of course extensive, but is generally in prose.

Peculiarly striking is the great mass of light lyric poetry from Hellenistic or early Roman times. A poignant "Paraclausithyron," or "Weeping outside the Door," by a woman; another, less good, by a man; several love-songs in loose Ionic metres (one starting with the poignant line *κατάκειμαι μεθ' ἑτέρον, σε μέγα φιλοῦσα*); soldiers' songs; sailors' songs; a song to the Rhodian winds; a song of spring in the woods; a lament by a boy who has lost his pet cock; a powerful though roughly written complaint, of Roman date, by a girl whose lover is being sent to fight in the amphitheatre as a *mirmillo*, and who desperately wants to buy him off; a charming quasi-philosophic flute-song, written in a tricky metre with a refrain (*αὔλει μοι*), the first letters of each stanza forming an acrostic.

Novels and Light Verse.—Our own commonest form of light literature, the novel, is also well represented. There are three fragments of the preposterously romantic *Chaireas and Callirhoe* of Chariton, which had evidently great popularity: one of Achilles Tatius. The new evidence shows that these romances are much earlier than was supposed, Chariton about 200 A.D. and Achilles about 300. There are also fragments of several novels hitherto unknown—*Semiramis and Ninus, Herpyllis, Chionê, The Dream of Nectanebo*, etc. The supply of novels is equalled by that of "Mimes," or short realistic dialogues for acting or reading aloud. They are poor stuff, illustrating p haps the pleasure in sheer coarseness which sometimes marks over-refined age.

More interesting are the poets who write under the inspirati of the Cynic "diatribê," or popular philosophical appeal conscience. The confusions and inequalities of Hellenist society stimulated a contempt for worldly standards and civilis conventions and a tendency to exalt the poor, the untaught, a the oppressed. In poetry this led to a revival of the scazons, "lame iambics," of old Hipponax, which affected both Cal machus and Herondas in later times, and has left us fragmen of a 3rd-century anthology, in which the chief figure is Phoen of Colophon. Better than these scazons are the "meliambi" Kerkidas the Cynic (*flor.* 250 B.C.), who is known as a friend the general Aratus, and is perhaps to be regarded as the auth of the anthology itself. They are full of strange words and fa tastic compounds which suit the mordant and rather brut style of his "diatribê." It is instructive to observe that Cl anthes the Stoic, when writing his more ideal exhortations, avoi the deliberately fractious metres and uses the harmonious hex meter or iambic.

In prose philosophy we have some striking specimens of 5t century sophistic; a fragment of Hippias (?) on Music, deridi the theories which invested it with subtle moral values; and tv of Antiphon the Sophist, known previously for his denunci tions of slavery, with a highly provocative treatment of th difference between *Phusis* and *Nomos*. There is also a fragme of a dialogue by that strange character, Aeschines Socraticu And meantime the charred remains of the library of the Ep curean philosopher at Herculaneum are slowly being deciphere much Philodemus, Polystratus "On Unreasoning Contempt ousness," with fragments of Demetrius Laco, and the Sto Hierocles. Nor should we forget the uncommonly interesti Epicurean Gospel, inscribed by Diogenes of Oenoanda on a lar wall, so that the world may read and be saved (2nd centu A.D.) "*Grammatikê*" or philology is represented by Chrest mathies, "Lives" or "Sayings" of eminent writers, by scho and glossaries and by a valuable fragment of Didymus' Co mentary on Demosthenes.

History, etc.—The additions to our historical literature a considerable. Besides the *Constitution of Athens* we have mo than 500 complete lines of a 4th century historian, who aft much controversy seems likely to be identified with Ephoru rather than with Theopompus or Cratippus. It deals chief with the year 395 B.C. Other fragments attributed to Epho treat the history of Sicyon and other subjects. There are sma pieces of Timaeus, the Sicilian historian, and of Philochorus, t Attic chronicler. There are bits of what seem to be the authen despatches of the third and second Ptolemies, and perhaps al of the first (*P. Oxy.*, 679), dealing with their own campaigns; al of Sosylus, who lived in Hannibal's camp, and, according Polybius, "gossipped like a barber," on the "Deeds of Hannibal Of Satyrus we have spoken above. There is some history al in the new fragments of the orators Lysias and Hyperides.

But both as history and as literature the largest and most su prising additions to our knowledge are to be found in the no literary papyri, of which there must be more than 10,000. Th may be divided into (*a*) official and (*b*) private, the first consisti of laws, rescripts, edicts, documents about taxes, judicial pr ceedings and the like, the second of contracts, receipts, wil manumissions and private letters or memoranda. Their val is increased by the fact that they often fall into large cohere groups, such as the papers about the Serapeum, the correspon ence of Cleon, the public architect, or of Zenon, the great esta agent. Combined with the rich mass of Hellenistic inscriptio these documents have illuminated the life and social history the Hellenistic age to a degree undreamed of before.

BIBLIOGRAPHY.—The new texts are to be found in the princi collections of Papyri, *e.g.*, B. P. Grenfell and A. S. Hunt, *The O rhynchus Papyri* (1898, etc.); *The Tebtunis Papyri* (1902) and *T Hibeh Papyri* (1906). See also *Berliner Klassikertexte, Berli Griechische Urkunden*, Boll. della Societa Papyrologica Italia

chiv für Papyrologie*, and the various publications of the British useum. The following separate publications are convenient (dates er to first edition): S. Sudhaus, *Menandri reliquiae* (1914); Schroeder, *Novae Comoediae Fragmenta* (1915); R. Pfeiffer, *llimachi Fragments* (1923); E. Diehl, *Supplementum Lyricum* 910); Hans von Arnim, *Supplementum Euripideum* (1913); E. iehl, *Supplementum Sophocleum* (1913); F. Bilabel, *Kleinere istorikerfragmente* (1923); F. Blass, *Bacchylidis Carmina* (1912); Crusius, *Herondae Mimiambi* (1923); B. Lavagnini, *Eroticorum aecorum Fragmenta Papyracea* (1922); A. S. Hunt, *Hellenica yrhynchia* with fragments of Theopompus (1909) and *Tragicorum aecorum Fragmenta Papyracea* (1912). Larger and more important e W. G. Headlam and A. D. Knox, *Herodas* (Cambridge, 1922); E. bel, *Sappho* (Oxford, 1925); J. U. Powell, *Collectanea Alexandrina* smaller fragments of poets of Alexandrine age, epic, elegiac, lyric d ethical (1925). See also the lists in W. Schubart's *Einführung in e Papyruskunde* (1918) and *The Greek Literary Texts from Greco-man Egypt*, by C. H. Oldfather, University of Wisconsin (1923); ilamowitz-Moellendorff, *Menander, Das Schiedsgericht* (1925).

(G. G. A. M.)

GREEK LITERATURE, MODERN (*see* 12.524).—The troubled ars from 1910 to 1925 were marked by one event of capital portance to the literature of modern Greece, the all but total nquest of the entire literary field by the spoken language, mmonly called the demotic or romaïc, after a century's struggle ith the official or scholastic tongue, called the pure or catharéussa.

In 1910, Costis Palamas published the remarkable narrative rical poem *The King's Flute*, in which he celebrates, in the oving atmosphere of Byzantium, the continuity of Greek roughout the ages. In *The Immutable Life* he appears as a bold novator, inspired by French intellectualism, and definitely esblishes his position as a poet of world wide fame. Before losing mself in memories of his childhood, as he does in his next work *ongings for the Lagoon*, 1912) he shows that he possesses the ernal spirit of ancient Hellas, of Byzantium and of modern reece. He is a poet of the intellect and of thought, whose work, hile showing the influence of Western symbolism, is yet filled ith imagery and with glowing verbal music. In works such as *mbs and Anapaests* and *The Grave* he has given expression to e deepest emotions. He was strongly influenced by the prohetic genius of Joannes Psuchares, a master in every *genre* of prose, ho introduced into Greece all the most recent linguistic theories. ithout his example it is unlikely that Palamas would have suceded in realising his powers. So was founded the new School Athens. Palamas, himself an occasional novelist and critic, ecame the centre of the popular renaissance.

Among the stylists pure and simple of the school we find John ryparis, a disciple of Hérédia; Laurence Mavilis, strongly inuenced by Italian literature, who was killed in the war of 1912; e Baudelairean Papantoniou Costas Ouranis; Aristos Camanis, whose work is chaste and, if anything, a little cold; and the elicate genius of Malakassis, who owes much to Moreas and to *he Intermezzo*. Peter Vlastos wanders from sphere to sphere, evelling in subtlety of rhythm and metre. All the storied past f Greece comes to life in his work. Apart from these, the dreamy ambros Porphyras has written his *Shadows;* Sotiris Skipis has ung of his longings for his own country (*Song of Apollo*) and the ufferings of the fugitives from Anatolia. Myrtiotissa in his movg work has sung of passion, while G. Souris and Pol Arcas ave turned to satire, and Drossinis, forerunner of many others, as produced his picturesque idylls.

But apart from simple melodists like these tardy Parnassians, he newer poets venture even further than Palamas into unharted territory. Among them are Angelos Sikelianos, who ediscovered the secrets of the ancient myths of sea and land, nd who hymns the greatness of life; Rigas Golphis, bitter, loquent and passionate; the fiery Varnalis, Ph. Yophyllis, who mbodies in his work the minutest details of modern life, and avaphis, who, apart from the others, evokes, in a strange and nadorned style, the Alexandrian decadence which resembles his wn depression.

Prose Writings.—Modern Greek prose is unusually rich both n *conte* and in the novel. The scattered but recently collected ork of Papadiamandis, who disappeared in 1908, remains unequalled. Carcavitsas and Ephtaliotis painted the sea and the islands, and left models for others, as also did the regretted poet, novelist, critic and translator, C. Hatzopoulos. Costis Passayannis, Vlakhoyannis and the Epirote Ch. Christovassilis are accomplished writers of the heroic and the picturesque. D. Voutyras is more deeply moved by the troubles of the working classes. There are also C. Theotokis of Corfu, who combined criticism of society with the study of character, and showed himself in his novels, *The Slaves in their Chains* and *The Life and Death of Karavelas*, as a cruel and unrelenting realist, also C. Paroritis, the powerful author of *Red He-Goat*, and Madame J. Dendrinos, who excels in depicting the ravages of passion. No one, however, in the novel or the theatre has excelled G. Xenopoulos, the creator of a whole gallery of pictures of Zante and Athens (*Isabel, Woman from Three Aspects*).

But Xenopoulos is not alone among Greek dramatists. Paulos Nirvânas, that fine critic and subtle observer, brought Ibsenism into fashion. Spyros Melas and Pandelis Horn achieved remarkable work with a high social aim, D. Tangopoulos distinguished himself in philosophical drama and N. Poriotis shows in *Rhodopi* that tragedy in verse is still to be found in Greece. Among the younger writers Constantinides in *Photinoula* reveals himself as a coming dramatist, and Valsa wrote a model of philosophic comedy in *The Council of Ministers*.

In other spheres, we may mention the names of J. Dragoumis as a critic, of Philindas and of Triandoephyllides in philology and the study of language, while we must not forget the well-known Psuchares, Lambros in history, Politis in folklore, Andréades in political and social economy, Xenopoulos, Nirvânas and Cambanis in literary criticism, Voutieridis in the history of literature. The influence of the literary reviews is shown by the fact that modern Greek literature is becoming more and more westernised in inspiration and form and ceasing to be Byzantine. (P. Le.)

GREEK RELIGION (*see* 12.527).—Our knowledge of this subject has been put on a new basis by researches into the beliefs of pre-Dorian Greece and Minoan Crete. N. M. P. Nilsson's conclusions, that a Mother-goddess and a divine child, who is born, is suckled by an animal and dies annually are characteristic of Crete and of the mainland, that this pre-Greek goddess survives in the Olympian pantheon as Athena and as Hera, that at Eleusis and many other places a cult was continuously practised from prehistoric times, and that the great cycles of Greek mythology all centre round sites important in the Bronze Age, are of the utmost value.[1]

How far this Minoan religion, which has clear affinities with Asia Minor, Philistia and Cyprus, was part of a general Aegean or even Mediterranean culture, we cannot yet say: Sardinia offers a remarkable point of contact.[2] These researches into prehistoric beliefs have transformed the study of Greek mythology. We recognise in it not a little confused history, even if Forrer's identification of Eteokles and Andreus, mythical kings of Orchomenus, with potentates mentioned in the Hittite tablets from Boghaz-Köi (*see* ARCHAEOLOGY: ASIA, WEST), should be seriously contested; we see in it also the reflex of old sacred traditions or rites (thus the death by burning of Herakles on Mount Oeta reflects a fire-ritual there annually performed), the influence of folklore motives distributed over a wide cultural area, and the effects of the desire to tell a good story for its own sake.[3] This study is in a favourable position, since Wilamowitz, Robert and others have done much to determine the earliest form and later developments of heroic stories,[4] while Nilsson, Eitrem, Farnell and many writers in *Religionsgeschichtliche Versuche und Vorarbeiten* have increased our knowledge of ancient ritual.[5]

Others, again, have investigated, not without exaggerations, the survival of ritual forms in drama and in the great games, and the gain to knowledge is clear, though it must be remembered that the search for a single origin of a human custom may well prove illusory, that a rite can arise independently or by parallel development in two places and that at the same time few rites or beliefs have developed unchanged by external influences. Not all athletic contests started as acts of homage to a dead man, but some did, just as all heroes are not degraded gods, but some (as, for instance, Hyakinthos) are.[1] Ritual origins can be forgotten; so could also the original meaning of certain survivals of primitive culture in historic Greece.[2] At the same time, the value of anthropological parallels appears in W. F. Otto's conclusions, partly based thereon, that in Homer the ψυχή or soul in Hades is not the θυμός or soul of the living man.[3] The study of cult has further shown how moral requirements grow out of ritual requirements, and how important is the group as contrasted with the individual.[4] In the study of cults and in particular of their geographical distribution has lain the chief advance in knowledge of Greek religion of the central period.[5]

[5] S. Eitrem's chief work is *Opferritus und Voropfer der Griechen und Römer* (Oslo, 1915). A good survey is F. Pfister's article "*Kultus*" in Pauly-Winowa Real-Encyclopädie.

Meanwhile we have learned much of the Hellenistic age as the period in which Eastern beliefs made their way into the West, and in which many of the religious phenomena of the Empire have their roots; among these are ruler-worship, astral and other mysticism, as also certain liturgical forms and the type of magic familiar in Roman Egypt.[6] Side by side with newer ideas the old worships lived on; there is no simple formula which expresses the religious attitude of the three centuries following Alexander's death. Survivals of ancient paganism in Christianity[7] and in modern Greek beliefs and folklore have been much discussed; on many important points agreement has not been reached, but much progress in detail has been realised.

GREELEY, ADOLPHUS WASHINGTON (1844–), American soldier and scientist, was born at Newburyport, Mass., March 27 1844. Enlisting in 1861 as a private, he served in the Civil War, and rose to be brevet major. In 1867 he was appointed second lieutenant in the regular army and became chief signal officer and brigadier general. While commanding at Lady Franklin Bay, one of the 13 international circumpolar stations, 1881–4, he reached, in 1882, 83°24′ N. 42°45′ W., the farthest north at that time. Two relief expeditions failed to reach him, and wh the third, under Capt. Schley, rescued him at Cape Sabine, but seven of his party were dead. From 1887 to 1906 he admi istered the Weather Bureau and the Signal Corps. Under hi were built more than 25,000 m. of cables and telegraph lines Alaska, China, Cuba; Porto Rico and the Philippine Islan Promoted major-general in 1906, he conducted relief operatio in San Francisco and put down the Ute rebellion. He serv with the international conference, London, 1904, at the reque of the British Govt. and was dean of the American delegati to the wireless conference at Berlin that year. Retired for a in 1908, in 1910 he was sent by President Taft to represent t United States at the coronation of King George V. He wro extensively on meteorological, electrical, geographical and oth subjects. His best known popular volumes are *Three Years* *Arctic Service* (1885); *Handbook of Polar Discoveries* (1909 and *Handbook of Alaska* (1925).

GREENOCK, Scotland (*see* 12.548), had a population 81,123 in 1921. The area of the borough is 2,945 acres. The are several large shipbuilding yards, and a torpedo factory. T old West Kirk is to be removed and re-erected at Seafield permit of the extension of Messrs. Harland and Wolff's shi yard. The new works at the harbour include a tidal basin and "always afloat" dock, the entrances of which are closed caissons to keep in 32 ft. of water at low tide. In 1921 the were three miles of quays in the port. Lady Alice Park was giv to the town in 1910, and Lady Octavia Park in the followi year; in 1919 Togo House was presented and opened as a m ternity hospital.

GREGORY, ISABELLA AUGUSTA, LADY (1852–), Iri playwright and author, was born March 5 1852, the younge daughter of Dudley Persse of Roxborough, Co. Galway. In 18 she married Sir William Gregory, a well-known Irish M.P. S produced many plays, essays, volumes of folklore, versions ancient sagas and romances concerning early Irish heroes, a did much to popularise the Anglo-Irish dialect of English spoken in the west. She translated for the Abbey Theatre se eral of Molière's plays into this dialect under the title of *T Kiltartan Molière* (1910). Her work as playwright and direct of the Abbey Theatre, in association with W. B. Yeats, w extremely fruitful. This theatre was opened in 1904 and La Gregory told its story in *Our Irish Theatre* (1914). Sir Hu Lane, whose life she wrote, *Hugh Lane's Life and Achieveme* (1920), was her nephew.

Among Lady Gregory's other works are: *Cuchulain of Mu themne* (1902); *Gods and Fighting Men* (1904); *Seven Short Pl* (1909); *The Kiltartan History Book* (1909); *Irish Folk History Pl* (1912); *The Golden Apple* (1916); *The Kiltartan Poetry Book* (1919 *The Dragon* (1920).

GRENADES (*see* 1.869 and 12.578).—A grenade is a sma metal missile, usually filled with high explosive, which may b thrown by hand or projected with the aid of a rifle. Grenad may also be charged with poison gas and incendiary or smok producing compositions, but the essential features of the vario kinds remain the same. Gunpowder grenades, made of woo bronze and other materials, were used in the 16th century, to b revived later in a high explosive form at the siege of Port Arthu in 1904 and in the trench fighting of the World War. Grenade are described as percussion or time grenades, according as t whether they explode on impact or after a definite time interva

Hand Grenades.—At the commencement of the World Wa the limited supply of grenades in the British Army was of th percussion type, in which a needle in the head of the grenade by direct impact caused to fire the detonator, a head-on fa being insured by means of tail streamers. At a later date, a all-ways fuse was suggested which would fire the grenade i whatever position it alighted. The main disadvantage of the pe cussion type is the danger of it exploding if accidentally droppe after being made "live" prior to throwing by the withdraw of the safety pin or other safety device. These consideratio led to the adoption of time grenades as being safer in action an allowing time in case of accident for the bomber to get clear o hrow away the grenade. Furthermore, time grenades are more asily improvised than percussion ones, and during the period of evere shortage of munitions in the World War, many such grenades were constructed locally out of any handy receptacle. For his purpose a short projecting length (usually 5 sec.) of safety use terminating in a detonator (for high explosive fillings) within he grenade was employed. Various friction or strike and cap ombinations were used to ignite the fuse before throwing.

The principle of the time grenade is represented in its greatest erfection in the Mills grenade (see fig. 1), invented during the War, f which enormous quantities were supplied to the British Forces. consists of a barrel-shaped iron casting, *a*, externally grooved in egments to ensure good fragmentation, and of a size to be coneniently clasped in the hand, weighing 1 lb. 8 oz. and containing ½ to 3 oz. of high explosive, *b;* amatol or ammonal in powder form convenient. The essential principle is that the ignition of the ime arrangement *c* is caused mechanically, as soon as the grenade eaves the bomber's hand. This is effected by the release of a triker *d* actuated by a powerful spring *e* which until then is retrained by a lever *f*. On withdrawing the safety pin *g*, this lever still held to the grenade by the thrower's fingers (see fig. 2), ut on the grenade leaving his hand, the loose lever flies off and cap *h* is struck which ignites the 5 sec. length of safety fuse *c*, which in turn fires the detonator *j* and explodes the grenade.

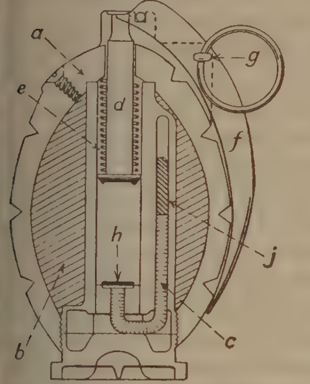

Fig. 1.—Section of Mills Grenade.

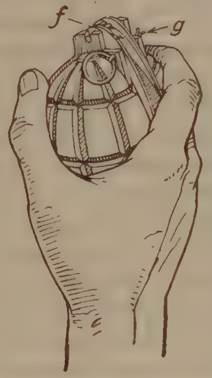

Fig. 2.—Grip for throwing.

Rifle Grenades.—Previous to the World War rifle grenades ad been designed in order to obtain an increase of range beyond he restricted limits of hand throwing. These grenades were of he percussion type with a steel tail rod, with or without a gas heck, which was inserted about 10 in. into the muzzle of the rdinary service rifle and propelled by the gases from a blank artridge, which impinges on the tail rod. The rodded rifle grenade described above is open to serious objections, being unhandy, nd liable to bulge and split the barrel, particularly if the rod is ot accurately straight and consequently tends to buckle. In ny case, a severe strain is thrown on the rifle, which is eventually ound to damage it. This led to the introduction from the French f the discharger-cup or *tromblon*, which is a short cylindrical cup ttached to the muzzle of the rifle, into which the grenade is fitted nd from which it is propelled by the gases from a blank cartridge fired in the rifle, acting on the base of the grenade. The Mills grenade can be adapted for firing from a discharger-cup y the addition of a gas check plate, which is screwed into the ase; the side of the discharger-cup holds the loose lever in position until the grenade is projected clear, when it flies off and sets he grenade in action. In this way rifle and hand grenades an be made practically interchangeable, thus simplifying both upply and transport in the field.

Future Design.—The tendency of future design is in the direction of percussion grenades, which are considered to be more effective than time ones, chiefly in that no time is given in which o get clear or to throw back the grenade before it explodes, in he event of the time fuse being too long in its burning. The chief difficulty to surmount is so to design the grenade that it is safe if dropped vertically by accident, but is made "live" in the space of a short flight. Other essential conditions are to act in any position of impact or fall after throwing, to be interchangeable with trifling adjustment as a hand or rifle grenade, to be weatherproof and mud proof and to be simple in manufacture and use.

GRENFELL, WILFRED THOMASON (1865–), British medical missionary, was born Feb. 28 1865 at Parkgate, Cheshire. He was educated at Marlborough and Oxford, where he took the degree of M.D., and studied medicine at the London Hospital under Sir Frederick Treves. At his suggestion Grenfell, in 1889, joined the Royal National Mission for Deep Sea Fishermen and for three years cruised with it in the North Sea as medical missionary. In 1892 he went to Labrador as first medical missionary and there did a great work, building hospitals, establishing homes and missions for the inhabitants, and organising industrial schemes and co-operative stores. In 1906 he received the C.M.G. in recognition of his services. Besides the work he did locally in Labrador and northern Newfoundland, culminating in the opening by King George of the Seamen's Institute at St. John's in 1912, Grenfell lectured in Canada, America and England in order to raise funds, and the mission expanded rapidly until, in 1912, its English, American and Canadian branches were united by the formation in New York of the International Grenfell Association, of which Grenfell became superintendent. During the early part of the World War he was attached as major to the Harvard Surgical Unit in France. In 1920 he became F.R.C.S. and in the same year received the gold medal of the National Academy of Social Sciences of America.

Grenfell's publications include: *Vikings of Today* (1895); *The Harvest of the Sea* (1905); *Labrador: the Country and its People* (1909, re-issued 1913 and 1922 with additional chapters); *Adrift on an Ice-Pan* (1910); *A Labrador Doctor* (1920, abridged 1925); *Northern Neighbours* (1923).

GRETNA, Great Britain, was the scene of a great undertaking during the World War. On a tract of land some 10 m. long and from one to two m. wide, partly in Dumfries, along the north shore of the Solway estuary, and partly in Cumberland, hundreds of stone, brick and steel buildings were erected for the making of munitions and providing for the wants of the workers who flocked there. These buildings included administrative buildings, schools, churches, messrooms, shops, halls, post-offices, fire-stations, etc., as well as factories, glycerine and ether distilleries, electric light and refrigerating plants. The buildings fell largely into two groups, one at Dornock to the west, and one about seven m. to the east at Mossband and Longtown. There were in addition two garden villages, one at Gretna, in the centre, and one four m. to the west at Eastrigg, with some 16 sq. m. of agricultural land, which has since been settled with ex-service men. The whole undertaking, about which great secrecy was preserved during and after the War, cost over £9,000,000 and employed at one time 24,700 people. It was sold in July 1924, although some members of Parliament made efforts to secure its use as a national factory.

GREY, ALBERT HENRY GEORGE, 4th Earl (1851–1917), British administrator, the son of Gen. Charles Grey, Queen Victoria's private secretary, and grandson of the 2nd earl, the Prime Minister (*see* 12.586), was born Nov. 20 1851; he was educated at Harrow and at Trinity College, Cambridge, where he graduated with a first class in law and history in 1873. As his uncle, the 3rd earl, had no children, Albert Grey was the heir-presumptive to the earldom, and he sat in Parliament as a Liberal, first for South Northumberland, and then for the Tyneside Division, from 1880 to 1886. The Liberalism which he displayed in the House of Commons and developed greatly in a crowded after-life was unlike the conventional Radicalism of the period. He was an enthusiastic social reformer, and a whole-hearted imperialist. He was one of the 93 dissentient Liberals who by voting against the Liberal Govt. decided the fate of the Home Rule Bill of 1886. He lost his seat in the ensuing General Election and did not reappear in Parliament till he succeeded his uncle in the earldom in 1894. The interval had been largely filled with travel—chiefly along the by-ways of the British Empire. He was in South Africa when his uncle died, and his knowledge of, and interest in, that country led to his appointment in 1895, after the Jameson Raid, as administrator of Rhodesia in succession to Dr. Jameson. There he became a close friend and ardent admirer of Cecil Rhodes, and it was natural that, on returning to England, he should join, in 1899, the board of the Chartered Company. He visited Lord Milner in South Africa after the Boer War, and returned once more in 1912 to unveil the Rhodes memorial on the slope of Table Mountain.

Canada, however, where he went as governor-general in 1904, was the part of the British Empire to hold the first place in his affections. He was no stranger there, but had already visited the Dominion twice, being brother-in-law of his predecessor, Lord Minto. His enthusiasm for the land and the people, his idealistic outlook, his bright and simple manner, his utter lack of conventionality and stiffness, his fondness for travelling and nature and sport captivated the Canadian heart. His term of office was twice prolonged; but Canada was loth to see him go in Oct. 1911, even though his successor was to be the Duke of Connaught. Never much of a party man, he was still less so after his return to public life in England. He devoted himself to the causes which appealed to him. Of these the Federation of the Empire was the first, and he would only contemplate Irish Home Rule as part of a federal scheme. He made a helpful contribution to licensing reform by the institution of the Public House Trust, and he worked hard for proportional representation. He forwarded all promising efforts for the improvement and organisation of agriculture. Lord Grey died at Howick, Northumberland, after a serious operation, on Aug. 29 1917, leaving, by his wife Alice Holford, a son who succeeded him in the earldom.

GREY OF FALLODON, EDWARD GREY, 1st Viscount (1862–), British statesman (*see* 12.588), became Foreign Secretary in Sir Henry Campbell-Bannerman's Ministry formed in Dec. 1905. Sir Edward Grey (as he then was) had previously announced that the Liberal Govt. would maintain Lord Lansdowne's policy of an *entente* with France and an alliance with Japan, and during the general election of Jan. 1906 he was asked by France, who was being pressed by Germany about Morocco, whether, in case of a Franco-German war, she could reckon on British assistance in arms. He replied that he could promise nothing which would not be fully endorsed by public opinion, but that, if war were forced on France through the *entente* respecting Morocco, he believed British public opinion would rally to her support. The French Govt. then suggested conversations between military experts.

After consulting the Prime Minister, the Chancellor of the Exchequer and the War Minister, he agreed, on the understanding that such conversations should in no way bind the British Government. The Algeciras conference on Morocco followed in the spring of 1906, and the constant support which, on his instructions, the British representatives accorded to the French helped to produce a satisfactory result and to strengthen the Anglo-French entente. In 1907 he came to an understanding with Russia. He concluded a convention with her about Persia, by which the integrity of that country was to be maintained, but Britain recognised that Russia had rights and interests in the northern zone and Russia recognised that Britain had rights and interests in the southern zone. In the same year he forwarded Anglo-American friendship by sending Mr. (afterwards Lord) Bryce to Washington as British Ambassador; and concluded a convention with Spain binding the Powers to maintain the *status quo* in the Straits of Gibraltar and neighbouring waters.

In 1908—the year in which Mr. Asquith, an intimate friend of Sir E. Grey, became Prime Minister—the European situation was considerably modified by the assertion in Oct. by Prince Ferdinand of the independence of Bulgaria and hi assumption of the title of King and the simultaneous annexation by Austria-Hungary of Bosnia and Hercegovina, which she had administered under the Treaty of Berlin. These strokes o policy moved the indignation of both the Russian people and the Russian Govt.; but the German Emperor announced that he would stand by his Austrian ally in “ shining armour ” and Sir E. Grey, though he protested against the infraction o the public law of Europe, was naturally unable to promis Russia anything more than diplomatic support. The action o the Central Powers confirmed him in the view that it was the who might be the principal danger to European peace; bu he was able to keep on friendly terms with them.

The labours of the Foreign Office, coupled with membership of the House of Commons, left him little leisure for forwarding the general policy of the Government. Nevertheless, as occasion arose, he defended all the principal controversial measures. His main preoccupation, however, was British relations with Germany, who gave dramatic notice of her dissatisfaction with the spread of French aims and influence in Morocco by despatching, at the beginning of July 1911, the gunboat “ Panther ” to the northwest African coast at Agadir, to protect, it wa alleged, German interests. In view of this further attempt to test, and if possible loosen, the entente, he issued a warning through the mouth of Mr. Lloyd George speaking at the Mansion House, that Britain intended at all hazards to maintain her place among the Powers. The warning sufficed to make Germany lower her tone, and subsequently Sir E. Grey explained to Parliament that the foreign policy of the Government was a continuation of Lord Lansdowne's and had got rid of the constan trouble with France and Russia; that British friendship with these Powers, far from constituting a hostile encirclement of Germany afforded a guarantee that neither would pursue an aggressive policy towards her; but that, when a nation had the bigges army and was increasing its already big navy, it was natural that other Powers should be apprehensive.

While a section of Radicals and Labour men were suspicious of Sir Edward's policy, public opinion in general (including the Conservative Opposition) supported him and was pleased when in the following year his able services were marked by the very unusual distinction, for a commoner, of the Order of the Garter In the beginning of 1912 he was a party to sending Lord Haldane on an informal mission to Berlin to reassure the Emperor and his Government as to the pacific intentions of Britain and to probe the intentions of Germany. The Cabinet formally notified the German Govt. that Britain would neither make nor join in, any unprovoked attack on Germany. But nothing would content the German Govt. but an absolute pledge by Britain of neutrality if Germany were engaged in war —a pledge which Sir E. Grey naturally could not give. Largely in consequence of this ominous rebuff, he exchanged letters on Nov. 22 1912 with the French Ambassador, agreeing that, if either Britain or France had grave reason to expect an attack by a third Power or a menace to the general peace, both Governments would consult whether they should co-operate and what measures they should take in common. Still he found himself able to work in general harmony with the German Govt in the efforts made by the Powers, in conference in London, to bring a settled peace to the Balkans, which had been distracted in 1912–3 by a series of local but furious and barbarous wars.

In this matter the diplomacy of Germany had appeared so reasonable that he was taken aback by her unyielding attitude in the negotiations arising out of the Austro-Serbian dispute As soon as he heard of the Austrian ultimatum delivered at Belgrade on July 23 1914, he realised at once that Russia could not allow Serbia to be crushed and exerted himself in the most strenuous fashion to save Europe from the threatened catastrophe. Acting generally in conjunction with France and Russia one or both, but in face of a lukewarm or hostile Germany, he urged upon Austria the extension of the alarmingly short time-limit of 48 hours; he proposed indefatigably various schemes for conciliation and conference; he pressed upon Serbia the essity of going as far as possible to meet Austria. In fact, bia accepted almost the whole of the Austrian demands; Austria would be content with nothing less than com- e submission, and on the expiry of the time-limit de- ed war on Serbia. On July 29 Germany, asserting that war inevitable if Russia attacked Austria, endeavoured to chase the neutrality of England by undertaking, if England ained neutral, to make no territorial acquisitions at the ense of France—an undertaking which did not extend to French colonies—and by promising to respect Belgian grity, after the War, if Belgium had not sided against many. Sir E. Grey next day absolutely refused to make bargain of the sort at the expense of France and Belgium. view of the apparent threat to Belgium, he asked France and many whether they were prepared to respect Belgian neu- ity provided it was not violated, and he asked Belgium ther she would remain neutral. France and Belgium both ied affirmatively, while Germany temporised. Hopeful otiations which had been begun directly between Russia and stria were wrecked by a German ultimatum to Russia to ntermand her mobilisation; and on Monday Aug. 3 Germany lared war on France.

he moment for decision had come for Great Britain. Russia asked her to declare herself against Germany and so give German general staff pause; France had asked her to co- rate as Germany was about to invade French territory. Cabinet had hitherto been divided, a strong section press- for the preservation of neutrality, and so Sir Edward had n unable to reply favourably to either Russia or France. now Germany had declared war on France, and was ap- ently about to disregard the neutrality of Belgium. The position, through Mr. Bonar Law, tendered support for ive measures to aid France and Russia; and Sir Edward, h a Cabinet rallying, with few exceptions, to his view, was to make an appeal in the House of Commons on Aug. 3 public and Parliamentary support to a policy of action. speech finally decided a wavering public opinion; with the eption of some Radicals and extremist Labour men, all parties, uding the Irish Nationalists, accepted the necessity of war. Edward demanded next day that Germany should respect neutrality of Belgium, and, on the German refusal, England nt to war.

ne of Sir Edward's first tasks was to turn the association the Powers fighting Germany and Austria into an alliance, ch bound its members to fight in common, and make peace ommon. In the course of the negotiations for this purpose he not hesitate to guarantee the support of Great Britain for attainment of long-cherished national objects, provided t these did not conflict with the aims of liberation and self- elopment common to the Allies: the most striking case ng the promise, after Turkey entered the War on the side of Central Powers, that Russia should have Constantinople. ch of his time and attention was occupied by difficult ques- ns arising out of the blockade of Germany and the consequent erference with the trade of neutrals. Public opinion in Great tain constantly complained that the blockade was not en- ced with sufficient strictness; while the United States, as principal neutral, harassed the British Govt. by repeated es. denouncing the methods of the British Navy as un- essarily prejudicial to American trade and contrary to inter- ional law. He was perhaps more successful in his answers to Americans than in his justification to the British public; and rge body of opinion in America accepted his explanations as sonable.

he tenure of the Foreign Office by a statesman so high- ded, sincere and experienced as Sir Edward Grey was rywhere regarded as such a valuable asset for Great Britain t it appeared only natural and fitting for Mr. Asquith, when templating the formation of a coalition government in y 1915, to lay down, as one of the essential conditions, that re should be no change in the office of Foreign Secretary. one could refute with such authority the intermittent assertions of the German Chancellor that it was England and not Germany that was responsible both for the origin and for the continuance of the War. When the pacifists called for negotiations in May 1916, he showed that when the Germans professed a readiness for peace it was only for a peace on the basis that Germany had won and the Allies were beaten; but the Allies were not beaten, and the first step towards peace would be taken when Germany began to recognise the fact. Credit must be given to Sir Edward for facilitating, in the early summer of 1915, the entry of Italy—till May 3 a member of the Triple Alliance—into the War against the Central Powers. It was, however, a bitter disappointment to him that his grave warnings failed to prevent Bulgaria, in the autumn of the same year, from taking the field against the Allies. Allied troops were sent to Salonika, and he offered Cyprus to Greece in order to induce her to carry out her treaty obligations and go to Serbia's aid against Bulgaria. But on this issue King Constantine won the support of his people against M. Venizelos, and Serbia was crushed before help could reach her.

In July 1916 an affection of the eyes, which had been giving him increasing trouble, made it advisable that he should have as much relief from work as possible, and he accepted a peerage. When a few months later, in Dec., his friend and chief Mr. Asquith was succeeded in the premiership by Mr. Lloyd George, failing eyesight and political comradeship both united to determine him to bring his 11 years' tenure of the Foreign Office to a close. He had served for a longer consecutive period than any predecessor, and in his official methods he carried out his own precept—that foreign policy required not striking effects nor bold strokes but careful steering.

After his resignation Lord Grey took little or no part in public life for several years. Happily, though he never regained normal vision, rest and quiet gradually worked a decided improvement in his eyesight. But, with the exception of a three months' mission in 1919 to the United States to deal with questions arising out of the peace, he did not definitely emerge from his retirement till 1922. It was the time of the decadence of the coalition government and Lord Grey urged that it was not trusted and should come to an end, which happened within a few months; he was also anxious to resuscitate the Liberal party, a process which was only partially effected. In foreign affairs he pressed for the re-establishment of good relations with France, and for the arrangement of an inclusive peace pact, beginning with France. When such a pact was concluded at Locarno in 1925 he welcomed it warmly. But the cause to which he devoted most of his energy was that of the League of Nations. He was especially anxious that Germany should be included as a member at the earliest possible date, and maintained that this should be the only business of the spring meeting of the League in 1926, which unfortunately separated without effecting it.

Much of his time in these years was taken up in the compilation of a straightforward narrative and vindication of his course in foreign policy, which was published in 1925 under the title *Twenty-five Years, 1892–1916*. He had published in 1899 another volume on *Fly-Fishing*, his favourite recreation. In 1885 he married Dorothy, daughter of Shallcross F. Widdrington, of Newton Hall, Northumberland. She was killed in a carriage accident in 1906, and in 1922 Lord Grey married, as his second wife, Pamela, sister of George Wyndham, widow of the 1st Lord Glenconner. (G. E. B.)

GRIERSON, SIR JAMES MONCRIEFF (1859–1914), British soldier, was born at Glasgow Jan. 27 1859 and joined the Royal Artillery in 1877. Noted from the outset as an exceptionally keen student of his profession, from 1896 to 1900 he was military attaché at Berlin. As a colonel he was with Lord Roberts during the advance from Bloemfontein into the Transvaal; but he was then transferred to China to act as British military representative on the staff of Count Waldersee, commander-in-chief of the Allied forces against the Boxers. In 1904 he was appointed director of military operations. He commanded the 1st Div. at Aldershot from 1906–10, and was in 1912 put in charge of the Eastern command. On the outbreak of the World War Sir J.

Grierson was selected for the command of the II. Army Corps. He proceeded to France, but died suddenly on Aug. 17 1914 while his troops were still assembling in the area of operations. A good linguist and unusually well acquainted with most of the European armies, Grierson had an understanding of "la grande guerre" and an intimate knowledge of the German Army that made his premature death an incalculable loss to the British cause.

GRIFFITH, ARTHUR (1872–1922), Irish politician, was born in Dublin March 31 1872 and began his working life as a printer. When the Irish party was divided over the Parnell case, Griffith, like Dublin artisans in general, sided with Parnell and against the clergy. But the rancorous quarrels which then disfigured Irish politics disgusted young men and led them to despair of success along constitutional lines.

New organisations came into existence in Dublin, the most important being the Gaelic League for the revival of the Irish language. Griffith joined this movement, but, since it was professedly non-political, his main activities were with the Celtic Literary Society, the leading figure of which was William Rooney. Over and above all these minor groups there existed the Irish Republican Brotherhood or Fenian Society, of which Griffith became a member. He went to South Africa in 1896, owing to lack of employment in Dublin, but home-sickness brought him back to Ireland in 1898. In 1899 *The United Irishman,* a weekly paper, was established, through the columns of which he was destined to influence Ireland.

Early Writings and Aims.—At first Rooney counted for more in the new movement than Griffith, for he possessed that personal magnetism in which Griffith was lacking, yet after his death in 1901, the paper strengthened rather than weakened. No such journalism had appeared in Dublin since the time of Young Ireland. It was savagely political; but its politics had an idealism which was foreign to the agrarian revolution. Griffith cared passionately for the things of the mind; his own writing had the beauty of trenchant steel; and he welcomed contributions from the best writers in Ireland, W. B. Yeats, "A. E." and the rest. No contributor expected to be paid, for all knew that Griffith himself lived on a pittance.

Later, when the power of his pen was recognised, generous offers were made to him, but he rejected them, and steadily pursued his own aim. That aim was both destructive and constructive. He sought first to divert his countrymen from the attempt to win self-government through parliamentary action at Westminster, and secondly to persuade them to work for it in their own country. Physical force was then popularly regarded as an illusion; and Griffith, though all his intimate associates were Fenians, recognised that the majority of Irish Nationalists did not think separation from Britain possible. He therefore resigned membership of the I.R.B., and aimed at winning over the separatists to work for a Parliament in Ireland united to that of England only by the link of the Crown. As a means to this end, he proposed passive resistance and an appeal to moral force. Payment of taxes was to be refused. Members elected to Parliament were to absent themselves from Westminster, and to sit in Ireland as a Council and govern only by the assent of the nation. Tribunals were to be set up to which cases should be brought, and the British courts were to be deserted.

Rise of Sinn Féin.—This policy was first publicly announced at a meeting in Dublin in Oct. 1902. The body which met called itself Cumann nan Gaodheal or "Society of the Gaels." But the name chosen to represent their policy was Sinn Féin "Ourselves"—Irish words which in their proverbial use mean roughly "Stand together." The name was soon transferred from the policy to its adherents. Candidates were put forward at municipal elections and by 1906 there were 14 Sinn Féiners on the Dublin corporation. But Griffith's propaganda was mainly confined to the capital; and in 1907 a member of the Irish party, who resigning his seat, stood for re-election as a Sinn Féiner, was heavily defeated. The attempt to return a Sinn Féiner to Parliament was not renewed for 10 years.

The new policy at first did not make much headway. Resistance to taxation proved difficult because all taxation except income tax was indirect, and a large proportion of income
payers were Unionists. The only effective forces were the
sonality and the pen of Arthur Griffith. His paper changed
name in 1906 when damages for libel were awarded against
United Irishman. That journal disappeared, and re-emer
as *Sinn Féin.* In 1907, when the Parliamentary party had
fered a reverse, *Sinn Féin* appeared as a daily paper, but
experiment soon had to be abandoned, and after another ba
ruptcy *Eire* became its name. Griffith wrote no books: but
published in 1905 a pamphlet called *The Resurrection of Hung*
which described how an almost vanished language had been
stored to national use, and how the elected deputies of an anci
nation, through a policy of abstention from the Austrian Asse
bly, gained full freedom under a dual monarchy.

The Volunteer Movement.—Griffith, during these years, tau
the rising generation to despise and distrust not only the meth
but the character of those who were then leading the
national movement and he was less scrupulous in his modes
attack than a publicist should be. Yet when it became clear
1911 that a Home Rule Bill was seriously intended, he
nounced his intention not to hamper Redmond. But the meas
proposed was wholly unlike his ideal and he condemned it
and branch, his most furious opposition being directed agai
that partition of Ireland which he was later constrained to acce
In the shaping of events, neither he nor his paper counted
much till the growth of the Ulster Volunteers revived the hope
the physical force party.

Griffith supported the counter-organisation of the Irish
unteers by word and deed. He was one of those who received
rifles landed at Howth in July 1914. The outbreak of the Wo
War revived all his importance. The Volunteers split,
tenths of them adhering to Redmond in support of the Brit
cause but the remainder, active and determined, remained
Ireland; and Griffith's paper was their main organ. The cens
ship attacked it, but instead of *Eire*, there came out *Scissors*
Paste, a journal consisting of extracts from war news arra
to give an impression very unfavourable to the Allies. It was
one of many journals. Griffith had founded a school, a "
quito press" and had set the example of tenacity and cour

The Easter Rising.—The Easter Rising of 1916 was a surp
to the majority of Irishmen. Griffith took no part in it,
thereby lost influence with the extremists. But the British
thorities remedied this by putting him into Frongoch, the
tention camp in Wales, which became a crowded academy
Sinn Féin. Yet when in July 1917 the prisoners were relea
Mr. de Valera was chosen as their leader. Griffith proposed
election at the Convention of Sinn Féin, while he himself retur
to his desk, re-issuing his paper as *Nationality;* this also was
pressed and re-appeared as *Eire Og*. He was again put in
in 1918. At the General Election after the Armistice, Sinn
swept the board outside Ulster, and Griffith's policy was put
force. The elected members (such as were not in prison)
sembled as Dail Eireann, the Irish Parliament. But, going
yond Griffith's plan, they declared for an Irish Republic, elect
Mr. de Valera as President and Griffith as Vice-President.
these men were then prisoners; but after some months the Pr
dent escaped and Griffith was liberated.

Griffith as Leader.—During Mr. de Valera's absence in Ameri
from June 1919 to the close of 1920, Griffith acted as head of
"Irish Republic." His policy now was carried out in its entire

During that struggle, power rested with Collins and ot
young men. Yet Griffith had still a great part to play. W
the truce was proclaimed and negotiations were opened in J
1921, Mr. de Valera refused to accept the responsibility of a
ing the full separatist demand. Griffith, thereupon, underto

leadership of the delegation which finally secured the in- sion in the treaty of the substance of Sinn Féin's original de- nd. Defending this settlement in the Dail, he spoke with the viction of one whose ideal had been accomplished and who w that it satisfied the desire of Nationalist Ireland in general. hout his authority, prestige and sense of realities, it is un- ly that any settlement of the difficult Irish question would e been reached.

lany of those who supported him would not accept the full sequences of the treaty; and when Mr. de Valera resigned, fith was elected President, not of the Free State, but of the ublic and the army continued to be in theory the Republican y. To meet the difficulty, Griffith set up a Provisional Govt. h Michael Collins as Chairman to carry on till a general elec- should have ratified the treaty. This resulted in an illogical ision of authority and as months passed Griffith's public erances as President were often contradicted by the action naction of the Provisional Government. During the final cussions with the British Govt. in June 1922, concerning the aty, he interviewed the leading Irish Unionists and pledged self to secure them full representation in the public life of the e State. His conception of Ireland was less narrowly Gaelic n that of Sinn Féin in general.

fter the elections on June 16, when a plain verdict was given acceptance of the treaty, the Government was at last forced take action against the mutinous section of the army. Civil began on June 27. In July the main bodies of the Irregulars re everywhere decisively beaten, and on Aug. 11 a force sent nd by sea occupied Cork, the last important town to be re- ned. On the morning of Aug. 12 Griffith fell dead suddenly on way to his office in Dublin. The strain had killed him, and completion of his life work was left to a younger generation. sentially he must rank as a publicist, an educator, an inspirer action. Few men in history have accomplished more for ir country than he by his unpaid pen. (S. G.)

RIMSBY, England (*see* 12.603), has an area of 2,868 ac. the county borough and of 1,798 ac. in the parish, with 117 of water and 248 of foreshore, and a population in 1921 82,355. The fishing trade has increased largely since 1910 has necessitated the provision of a new dock; there are siderable imports of timber and ice, and the town has some factories. The tramways were taken over by the corporation 1925. St. Augustine's Church was built in 1911, St. Luke's 1912 and St. Peter's (Roman Catholic) in 1919; a new parish, t of St. Stephen's, was made in 1911. A children's home in ighowgate was opened in 1913, and Queen Mary's hostel, built the National Mission to Deep Sea Fishermen, in 1925. A War emorial in Bargate was unveiled in 1921. The Grimsby wlers and their crews did splendid work in sweeping for nes during the World War (*see* MINELAYING).

GROSSMITH, GEORGE (1847–1912), British comedian (*see* .619), died at Folkestone March 1 1912.

His son, GEORGE GROSSMITH (1874–), British comedian, d third of the name, who made his first appearance at the aftesbury Theatre in an operetta by his father, became a well- own figure in musical comedy, especially at the Gaiety Thea- London. He was the author, or part author, of many musical ys, songs and revues, and took a leading part in popularising ue in London. Together with Edward Laurillard he became see and manager of several London theatres. During the rld War he served as lieutenant in the R.N.V.R.

GRUNDY, SYDNEY (1848–1914), British dramatist (*see* 12.640), d in London July 4 1914. His last play, *A Fearful Joy*, was blished in 1908.

GUAM (*see* 12.648).—American naval station in the North cific, the largest of the Marianas Islands. The native popu- ion. 60% of which lives in the chief town, Agaña, was 14,912 June 30 1923, and 15,160 on June 30 1924. On the latter date ere were also living on the island 550 non-natives, besides the rsonnel of the naval establishment amounting to 814. With non natives are included the families which are the result marriages with native women.

Production.—Agriculture is the chief occupation, and the Government is making efforts to develop this, so that the island may be more nearly self-supporting and have a larger surplus for export. Copra is the chief crop and about the only export, the normal crop being about 800 tons. In 1923–4 the first coconut-oil mill in the island was erected. Maize and other foodstuffs grow readily. A good grade of coffee is produced, and excellent tobacco can be grown. Fish are plentiful in the waters surrounding the island, but the fishing industry has never been developed to its full capacity, and fish foods are imported.

Education.—Education is compulsory up to the age of 12. In 1923–4 there were 16 primary schools, one intermediate school, one high school and one school for Americans, besides two private schools. Pupils attending the schools were 2,833, of whom 2,676 were in the public schools. The number of American teachers increased from 4 in 1922–3 to 14 in 1923–4. Teaching is in English. Athletics are a recognised part of the curriculum, and baseball is played enthusiastically throughout the island. About 40% of the public receipts are expended on education.

Finance and Trade.—The revenues for the fiscal year 1923–4 amounted to $137,805, and expenditures to $152,781. Revenues for 1923–4 included land taxes, about $42,000; licences, about $15,300; court fees and fines, about $10,650; customs and revenue collections over $9,000 (approximately $6,657 being customs collections); and productive industries, about $27,600. The Government is also collector of customs and revenues. The balance of trade is heavily against Guam. Imports and exports in 1923 were valued at approximately $674,556 and $94,086, respectively, and in 1924 at approximately $632,721 and $66,095 respectively. In 1923 1,432,568 lb. of copra were exported to the United States, and in 1924 2,110,000 pounds. The heaviest import is of food supplies, amounting in 1924 to over $245,000. The only banking institution is the Bank of Guam which was established by the Naval Govt. in 1915, for general banking business and as a depository of the Naval Govt. of Guam. It has a capital stock of $15,000 fully paid up. On June 30 1924 its surplus amounted to $29,000.

Administration.—The administration is directly under the Department of the Navy, and the Governor is a naval officer with the rank of captain who is appointed by the Secretary of the Navy. The Governor has full power and authority to make laws for the government of the island, from which there is no appeal. He is assisted by a native Congress which has only advisory power. The Guam Congress on July 1 1925 resolved that the Congress of the United States be petitioned to enact a law making all native Chamorros of Guam citizens of the United States, or that Congress grant them the privilege of becoming citizens of the United States by naturalisation. The cadastral survey is proceeding rapidly and new roads are being constructed. The Dollar Line has established a regular service to Guam, and there are regular sailings to Manila and Japan. Recent public improvements are a new post-office in Agaña, the capital, school buildings and a number of roads.

GUATEMALA (*see* 12.661).—A republic of Central America and a member of the League of Nations. Its estimated area is 48,250 square miles. The capital, Guatemala City, was completely destroyed by earthquake between Jan. 25 1917 and Jan. 24 1918.

I. POLITICAL HISTORY

Guatemala was little affected by the World War, but on April 27 1917 she broke off diplomatic relations with the German Govt., and on April 23 1918 adopted "the same belligerent attitude as the United States." Guatemala was one of the signatories to the Treaty of Versailles June 28 1919. In 1915 Manuel Estrada Cabrera, who had been dictator since 1898, was re-elected for the term 1917–23. In 1920, however, a group of intellectuals known as the Unionist party opened a newspaper campaign against him, which developed into a revolutionary movement and spread to the National Assembly. When the army became infected Cabrera resigned (April 1920) in favour of the vice-president, Carlos Herrera, who was elected President by the National Assembly. His Government was promptly recognised by the Powers. Herrera, who had wide experience of agriculture, banking and commerce, aimed at encouraging foreign capital, stimulating immigration and internal development. He worked energetically to repair the damage caused by the earthquake of 1917–8, and erected many valuable public buildings. On Oct. 10 1921, after prolonged preliminary negotiations, Guatemala, Honduras and Salvador signed a pact of union at San José, agreeing to form a Central American Union. (*See* CENTRAL AMERICAN UNION.)

Each state, for the time, was to conduct its own internal affairs; but the signatory states were to constitute a unit on foreign affairs and for matters of common interest. Costa Rica and Nicaragua failed to enter the Union. On Dec. 7 1921 the Opposition overthrew Herrera, leader of the Unionist party which was favourable to the Union, and Gen. Orellana, leader of a military faction, was elected President in March 1922 for a term of six years. A revolt against him in July was put down with bloodshed. Pres. Orellana repudiated the Pact signed on Aug. 20 1922 by Nicaragua, Honduras and Salvador (*see* CENTRAL AMERICAN UNION) on the ground of avoiding "entangling alliances." His Government was represented, nevertheless, at the Washington Conference of 1922–3 and signed the conventions there agreed upon. In June 1924 it was the first Central American republic to adopt the international commissions of inquiry provided for by the Washington Conference. The National Assembly ratified the general Treaty of Peace and Amity there drawn up.

In Aug. 1924 Guatemala reached an agreement with the United States, according mutual most-favoured-nation treatment in customs, and in Nov. effected a commercial treaty with Germany on the same principle. By a decree of April 28 1925 all foreign companies domiciled in Guatemala must appoint a representative for legal and non-legal transactions. In April 1925, also, women obtained independent legal personality. Under the 1923 general Treaty of Peace and Amity, Guatemala agreed to limit its armed forces for a period of five years to 5,200, and moreover to restrict aircraft to 10 aeroplanes and to maintain no navy.

Education.—Primary education is free and compulsory between the ages of 6 and 14. In 1917 there were 1,942 government schools, with 54,479 pupils in attendance. After the destruction of Guatemala City by earthquake in 1917–8 education suffered a check until 1924, when it received special attention. In 1924 there were 1,477 Government schools, and a number of private secondary, professional, normal and vocational schools, as well as four schools of commerce. There were 94,177 pupils in attendance and 4,284 teachers.

II. SOCIAL AND ECONOMIC CONDITIONS

The census of 1920 gave a population of 2,004,900, and the estimates for 1923 were 2,454,000. About 60% of the population are pure Indians. In Oct. 1924 a contract was authorised for the admission of one hundred Czechoslovak farmer families, for whom were assigned 4,500 hectares of undeveloped lands. Dwellings, medical attendance, schools and hospital service were included in the contract.

Finance.—A new monetary system was introduced in Nov. 1924, with the quetzal (equal to the dollar) of 1·504665 grammes of pure gold as the unit, having a value of sixty pesos. It was to be coined in 5, 10 and 20 quetzal denominations, with subsidiary silver and copper coins. The silver peso in Oct. 1924 was worth $.5376, although only unconvertible paper currency was then in circulation. Provision has been made since Feb. 1925 for a circulation reserve fund, by a tax of an added 50 cents a quintal on coffee and a graded tax of 20 to 30 cents on sugar exports.

The Government budget for the years 1921–4 was (in pesos)

	Expenditures	Revenues
1921	387,365,234	256,261,970
1922	348,489,894	306,810,074
1923	396,121,964	385,874,260
1924	471,969,841	466,190,332

In 1924 revenue in quetzales was 8,101,686 and expendit 8,095,573. Current expenditure for 1921 deducting items requiring cash outlay, such as amortisation of the external deb transfer securities in London to the Council of Foreign Bondhold was actually only 324,049,887 pesos. Increase in 1922 revenues largely due to the high rate of foreign exchange and to collectio the export tax on coffee in gold.

The total debt Dec. 1922 was £1,908,563 constituted as follows $1,257,898, 11,923,401 silver pesos and 181,887,314 paper pe At the end of 1924 the external debt was considered as £1,875 and the internal debt £1,426,961. The total debt was then in dol 13,239,240.

Industry.—Exports mainly consist of coffee and sugar; cotton bananas are among the growing exports. The figures of the ye 1922–4 for the exports of coffee, sugar and bananas were:—

	Coffee (lb.)	Sugar (lb.)	Bananas (bunches)
1922 . .	94,000,000	24,000,000	3,884,170
1923 . .	96,000,000	27,000,000	4,384,077
1924 . .	89,000,000	18,000,000	5,547,531

The principal imports are cotton goods, flour and other foodstu The average wheat production is 400,000 bu., equivalent to 90, barrels of flour. Milling is not commercially developed. During year preceding May 1 1925 the cotton crop reached 30,000 quint a large increase in spite of poor crops in certain parts. Commer conditions in 1925 were excellent, due to high coffee prices. portation of automobiles and other luxuries was heavy. Imp duties for 1924 amounted to 19,921,316 pesos and $3,009,315, total of 3,341,336 quetzales. Exports produced revenues of 56, pesos and $1,435,492, or a total of 1,436,437 quetzales. A bank decree stabilising exchange aided merchants in the conduc business.

A contract for developing petroleum fields by a New company in the departments of Ezabal and Alta Verapaz was proved in Nov. 1924. Another contract provided for similar deve ment in Alta Verapaz, Quiché and Huehuetenango. Changes in mining and petroleum development law make the sole tax 10 cent on the gross product in two zones and eight per cent in others. Contracts endure 40 years; the geological surveys begin within six months from the date of the concession.

The foreign commerce for 1913 showed imports worth $10,062, and exports worth $14,450,000. For recent years the figures were

	1923	1922	1921
All countries			
Imports . . .	$10,840,781	$10,751,660	$13,369,6
Exports . . .	14,725,567	12,065,949	12,130,8
United Kingdom			
Imports . . .	1,665,643	1,599,131	2,289,0
Exports . . .	355,249	306,591	133,6
France			
Imports . . .	307,148	355,678	480,1
Exports . . .	24,694	17,977	11,9
Germany			
Imports . . .	1,302,267	1,199,910	1,240,3
Exports . . .	2,047,320	1,961,395	1,757,3
United States			
Imports . . .	6,519,630	6,644,449	8,177,4
Exports . . .	11,330,986	7,883,386	8,114,1

For 1924 the exports to the United States were $10,089,156, the imports $8,823,542.

Communications.—British interests in the International Railw Co., incorporated in 1912, and controlling 597 m. of railway, acquired by American capitalists in 1924. A branch is to be structed from the Mexican boundary and the Caribbean coast the Southern end of Salvador. A new line south to Asunción has been approved by the minister of promotion. A private building programme, initiated in 1924, provides for the buildin new roads from Guatemala City to San Jose; from Antiqua Panajachel, thence to Quezaltengo; and from Guatemala to Sa Ana in Salvador. The first of these will serve important coffee sugar export interests. Three wireless stations largely suppl telegraph lines, which are difficult to maintain in the tropical for They are at Quezaltenango, a gift from Mexico, Puerto Barrios at the capital.

UCHKOV, ALEXANDER (1862–), Russian politician, born in Moscow. He studied at the universities of Moscow Berlin and, after leading an adventurous life of travel, en- d politics. He helped to found the Russian "Octobrist" ty in the hope that the Tsar's Govt. would work with the mod- te Liberals of the Zemstvo, while safeguarding the monarchical iciple. In 1910 Guchkov was elected president of the Duma, as Stolypin became more reactionary, the Octobrists lost ir standing ground, and Guchkov eventually resigned the sidentship of the Duma. In the elections to the fourth Duma failed to secure a seat. During the World War, however, he in charge of the Red Cross organisation on the German nt, and devoted his energies to refitting the army on the hnical side. When the March Revolution of 1917 broke out chkov became Minister of War, but he was powerless against mounting flood of desertion and demoralisation in the army, resigned in despair. Emigrating he found himself without per place and influence, and later took refuge in Paris, where pleaded for a reunion of all parties against the Bolsheviks.

UERRINI, OLINDO (1845–1916), Italian poet (*see* 12.672), l at Bologna Oct. 21 1916.

UESCHOFF, IVAN EVSTRATIEW (1849–1924), Bulgarian itician, was born at Philippopolis Feb. 1849. He was educated t at Philippopolis, and was then, in 1865, sent to Owens Col- e, Manchester, for four years. He remained at Manchester usiness with his father until 1872, when he returned to Bul- ia. In 1877 he was arrested by the Turkish governor and demned to death for political propaganda against Turkish , but was saved by the intervention of the British and Amer- n Consuls. He then began to send accounts of the Turkish ocities to *The Times* and *The Daily News* (London). In 1878 eschoff became general manager of the Bulgarian National nk at Sofia, and was Minister of Finance from 1894 to 1897. was elected president of the Sobranie (National Assembly) 1901 and became Prime Minister in 1911. As such, he con- ded defensive alliances with Serbia, Greece and Montenegro inst Turkey, and so paved the way for the Balkan victories 1912. After the London peace treaty, May 30 1913, Gueschoff igned with his Cabinet. During the World War he retired m politics and became president of the Bulgarian Red Cross. died at Sofia March 11 1924.

GUESDE, JULES BASILE (1845–1922), French socialist (*see* 672), died in Paris July 28 1922.

UIANA, BRITISH (*see* 12.676).—The sole British possession the continent of South America, has an area of 89,480 sq. es. The population of the colony at the end of 1924 was ,204.

ugar maintains its position as the principal export from tish Guiana; of the area under cultivation 57,000 ac. are ped. The value of the sugar exported in 1924, with its by- ducts—rum, molasses, molascuit—was approximately £2,- ,000. Between 1915 and 1924 machinery to the value of 500,000 sterling was imported for the equipment and improve- nt of the sugar factories. Exports of rice in 1924 were valued £65,120, an increase on the exports for 1923, which were ued at £57,018. The production of diamonds has increased ce 1913; in 1923 214,385 carats were exported, valued at 32,585. The output of gold has decreased; in 1924 the orts were valued at £19,600, as against 63,803 ounces exported 1914 and valued at £232,085. The value of bauxite exported 1924 was £176,200, and in the same year balata valued at 4,400 was exported. The chief imports are foodstuffs, manu- ured textiles and machinery. Under the British preferential ff imports from the United Kingdom, Canada and other British possessions have increased, while imports from the United States have decreased.

The forest area of 78,000 ac. contains many valuable woods—greenheart, which is produced only in British Guiana, and mora, both of which are suitable for shipbuilding and are resistent to marine borers, purpleheart and crabwood. 168,454 cu. ft. of timber, valued at £26,006, were exported in 1924. Difficulty of access has limited the exploitation of the mineral and timber wealth of the colony to the northern half. The development of the forest lands is being actively pursued by the newly-created Forestry Department, which began its work of locating fresh sources of supply of commercial timbers in Nov. 1925. British Guiana participated in the British Empire Exhibition in London 1924–5, and a resident trade commissioner has been appointed in London.

GUIANA, DUTCH (*see* 12.680).—The only Dutch possession on the South American mainland, has almost doubled its population since 1910. Statistics obtained in 1925 gave the population as: Europeans, 1,422; natives, comprising Indians and bush negroes, 56,339; Javanese, 18,685; Hindus, 30,974; Chinese, 1,454. The population of the capital, Paramaribo, in 1925 was 44,772. In 1923 there were 35 public schools in the colony with 5,296 pupils in attendance, a Government normal school with 127 students, and 55 private schools attended by 9,481 pupils.

The shortage of labour that followed on the abolition of slavery in 1863, causing the reduction of the plantations from 500 to 5 sugar plantations and 66 for other products, created a labour problem that led to the introduction of Chinese, Javanese and Hindus as contract labourers. The chief products are sugar and coffee; next in importance come bananas, rice and cocoa. Cotton is produced on a small scale, and oranges and coconuts are grown by the crofters, many of whom were originally contract-labourers. The principal articles of export are sugar, coffee, bananas, cocoa, balata. Timber is furnished from the hinterland and gold is mined in many districts. Important deposits of bauxite are known to exist in the colony, but hitherto this mineral has not been worked on any large scale. The balance of trade is usually adverse, and the deficit is adjusted by an annual subvention paid by the Netherlands Government. During the four years 1922–5 the sum required for the state subvention has progressively decreased. Imports in 1924, mostly foodstuffs and manufactured articles, were valued at £624,704. Exports, consisting of agricultural and mineral products, besides timber and balata, were £617,453 during the same year.

See J. M. Brown, *The Dutch East* (1914); A. S. Walcott, *Java and Her Neighbours* (1914); also *Jaarcijfers voor het Koninkrijk der Nederlanden*, annual publication of the Colonial Office, The Hague. (J. C. K.)

GUIANA, FRENCH (*see* 12.681), has an area of about 32,000 sq. m. and a population (1921) of 44,202, including 2,368 Indians (natives). Some Indian tribes may have escaped enumeration, but in any case the colony is very sparsely inhabited. About 10% of the people are whites and another 10% negroes; the remainder are mostly of mixed blood and locally are called Creoles. Cayenne, the capital and chief port, had 10,146 inhabitants; St. Laurent du Maroni, 1,300. The colony is best known as a penal settlement and as including the Iles du Salut, one of these islands being the notorious Devil's Island. The 1921 census figures included 3,775 convicts.

The natural resources of the country remain very little developed. The chief industry is gold mining, the gold produced representing fully half the value of the exports. The mines are near the Dutch and Brazilian frontiers respectively. The forests contain valuable timbers. Rosewood is exported and there are factories for the extraction of rosewood essence. Balata is also obtained from the forests. Small quantities of coffee, cocoa and sugar figure in the exports, but labour is scarce and dear and only a very small portion of the land is cultivated. The adverse trade balance in 1921 was 25,000,743 francs. The cost of the penal settlement is borne by France. There are few roads and but 15 m. of railway. A seaplane service is maintained between Cayenne and St. Laurent and there is a wireless telegraph station. The colony is represented in the French Parliament by one deputy. See *Le Journal de la Société des Américanistes de Paris*, for articles on the history and explorations of the country.

GUILD SOCIALISM: *see* SOCIALISM.

GUILLAUMAT, MARIE LOUIS ADOLPHE (1863–), French soldier, was born at Bourgneuf, Charente Inférieure, Jan. 4 1863. He left the military school of St. Cyr in 1884, and became a captain in 1893. He served for three years in Tongking with the Foreign Legion, and during the Boxer rising in 1900 was in Tientsin where he received his first wound. In 1903 he was appointed professor of military history at St. Cyr and in 1908 lecturer on infantry tactics. After being director of infantry at the Ministry of War from 1911, he became *chef de cabinet* to the Minister of War, M. Messimy, in 1914. At the outset of the World War, Guillaumat, who had already taken part in 12 campaigns, commanded a division at the battle of the Marne and later in the Argonne. Subsequently, in command of the I. Army Corps, he took a notable part in the battle of Verdun and the Somme. In Dec. 1916 he was given the command of the II. Army in front of Verdun and directed the attack of Aug. 20 1917, which succeeded in freeing the position.

In Dec. 1917 he was sent to Salonika as commander-in-chief of the armies in the East (*see* SALONIKA CAMPAIGNS) but was recalled in July 1918 to take command of the entrenched camp at Paris in face of the enemy advance. He urged the launching of an offensive in Macedonia both at the Inter-Allied War Council at Versailles and before the British War Cabinet; and on Sept. 4 1918, at the London conference, his advice was adopted. In Oct. 1918 Gen. Guillaumat was given the command of the V. Army on the Aisne for the final advance. After the war he was president of the commission of inquiry into the surrender of the frontier fortresses and later was elected a member of the Conseil Supérieur de la Guerre. After being entrusted with a mission to Athens, where he drew up a plan for the reorganisation of the Greek army, he took command of the army of occupation in the Rhineland at the end of 1924.

GUILLAUME, CHARLES EDOUARD (1861–), French physicist, was born at Fleurier, Switzerland, Feb. 15 1861. Educated at Neuchâtel, he became a *docteur-ès-sciences*, and devoted himself to the study of practical physics. He is principally known for his invention of the metal, invar, an alloy of nickel and steel which, having a co-efficient of linear expansion of only ·0000008 for one degree Centigrade, is in general use as a material for standard measures and instruments of precision. In 1920 he was awarded the Nobel Prize for physics and he became director of the international bureau of weights and measures.

Guillaume's works include: *Traité pratique de la thermométrie de précision* (1889); *Les radiations nouvelles; Les rayons X, etc.* (1896); *Les applications des aciers au nickel* (1904); *Détermination du volume du kilogramme d'eau* (1910); *Compensation des horloges et des montres* (1921); *Les récents progrès du système métrique* (1907–21).

GUINEA, FRENCH (*see* 11.102). Revised estimates give the area as 90,000 sq. m. and the population (1925) as 2,000,000. There were 2,000 Europeans, of whom half were French. From the port of Konakri (population 9,000) a railway 411 m. long was completed in 1915 to Kankan, on the Upper Niger. Palm oil and kernels, ground nuts, rubber and hides are the chief exports. Since 1922 cotton has been grown in the Niger regions. Coffee and bananas are other crops.

GUISE, BATTLE OF: *see* FRONTIERS, BATTLES OF THE.

GUITRY, LUCIEN GERMAINE (1860–1925), French actor (*see* 12.705). In 1920 he came to London with his son Sacha, and achieved an immense success in *Pasteur*, when he played the title rôle. He also played in his son's play, *Mon père avait raison.* He died in Paris June 1 1925. Sacha Guitry's play, *Deburand*, had a successful run in New York and London.

GULLSTRAND, ALLVAR (1862–), Swedish physician,
born June 5 1862 at Landskrona. In 1894 he became professo
diseases of the eye at Uppsala and in 1913 was appointed
fessor of physiological and physical optics at the same univers
His investigations concerned the general laws of dioptrics, a
conception of the theory of optical images; the extrication of
optical images in the eye, and the eye's relation to the diffus
of light. In 1911 he was awarded the Nobel Prize for medic
Among Gullstrand's works are *Allgemeine Theorie der mono*
matischen Aberrationen (1900), *Die optische Abbildung in het*
genen Medien und die Dioptrik der Kristallinse des Mens
(1908) and *Einführung in die Methoden der Dioptrik des A*
des Menschen (1911). He received the honorary degree
Sc.D. at Dublin in 1912 and became honorary member of
Ophthalmological Society of the United Kingdom in 1916.

GUN: *see* ARTILLERY; ORDNANCE.

GUNNERY, NAVAL.—It is no easy matter to hit, and keep
hitting a moving target at sea, with a gun mounted upon an
stable platform that is also moving in relation to the tar
With a single gun firing, at short ranges, the gunlayer can fol
the path of his shot and see it strike the water or target, and
correct his sights so that the next shot will hit. With sev
guns firing, under battle conditions at even moderate ran
this becomes a sheer impossibility for anyone stationed at
guns. Hence the necessity for controlling the fire of the guns
ship from a central position remote from the guns themsel
The control officer is usually stationed high up in the ship wh
he is in a good position to spot the fall of the shot and has all
available information for estimating the hitting range and
communicating it to the guns. The gunlayers keep their g
continuously laid upon the target and the guns are fired at
command of the control officer.

Let us consider a simple case of a ship firing at a towed tar
at a range of about 10,000 yards. The range of the target is
tained by the rangefinder and certain corrections, which wil
explained later, are applied to the rangefinder range to obt
the estimated " gun range " which is passed to the guns. As
firing ship and the target are both moving, it is obvious that
range must be changing at a certain rate. This rate of chang
range is estimated and is applied to the gunsights at set inter
The deflection is estimated by the control officer and is appl
to the sights. The control officer then fires a salvo of two or m
guns and watches the fall of the shot. He makes a spotting
rection in range and deflection, calculated to get the next sa
to fall, if possible, upon the other side of the target to the
one. If this happens he halves his original spotting correct
applies it in the opposite direction and fires again. This t
salvo should fall very close to the target, if it does not hit,
if the rate of change of range has been estimated correctly,
sequent salvoes will, theoretically, continue to hit. This is a
simple case of a bracket system, which is used in one form
another by all control officers.

Corrections.—The corrections which must be applied to
range observed by the rangefinders in order to obtain the hit
or gun range are due to (1) the variations in muzzle velo
caused by the wear of the guns, (2) the change in muzzle velo
due to changes in the temperature of the charges, (3) the di
tion and force of the wind and (4) the height of the barom
and thermometer. The first two are usually applied as a cor
tion upon the sights of each individual gun and remain more
less constant for any one day. The last two factors are varia
from hour to hour and are applied as a direct correction to
rangefinder readings. The rate at which the range is changing
variable factor since it depends upon the relative bearing betw
the two ships, which is constantly changing. The same appl
in a lesser degree, to the deflection, and constant corrections
necessary in both rate and deflection to maintain hitting a
it is once established.

Increase of Range.—Thus there are many problems to
solved, even in the simple case of firing at a target at 10,
yards. Battle ranges have now been extended up to 20,000
or more, and as the range is increased the problems with wh

control officer is faced become much more complicated. At ges which approach the limits of visibility the observation of fall of shot becomes extremely difficult, and it is practically ossible to tell whether shot are falling over or short, unless are falling directly in line with the target. As the range eases errors caused by the roll, yaw and pitch of the ship, h at moderate ranges are not so serious, become accentuated have to be taken into account.

rial and Error Process.—The trajectory of the shell reaches ry high altitude and the wind and atmospheric conditions he upper air cannot be known with sufficient accuracy to en- a correct forecast to be made of the effect upon projectiles. effects of the variations in muzzle velocity, due to the wear he guns, to changes in the temperature of charges and to r more obscure causes, become more pronounced. Range ob- ation, even with the most perfect instruments and with the trained observers, becomes unreliable when the visibility is r and the errors in the rangefinders themselves become ter as the range increases. It thus becomes a matter of great culty to make an accurate forecast of the initial gun range deflection. It has become the practice to obtain the hitting ge by a process of "trial and error," employing a large bracket em and using the gun as its own rangefinder, obtaining what stance is possible, under prevailing conditions, from the in- ments of observation. This can be done as long as the fall hot can be observed, but becomes impossible as soon as this dition ceases to exist. The use of aircraft to assist the spot- officer, or to carry out the whole of the observation of fire at eme ranges, naturally suggests itself, and it is in this direc- , followed by the possible introduction of some form of irect fire, that future developments may be expected.

THE MECHANISM OF FIRE CONTROL

he installation used for the control of fire was intricate in years before 1914, and War experience has made the addition urther complications necessary. Little can be said of the de- s of the various instruments used, as the majority of them are fidential, and the functions, and even the existence, of some hem are kept as secret as possible. The main problems are the e for all and may be divided into three parts:—

1) The communications between the control stations and guns.

2) The apparatus for obtaining the hitting range and de- tion and for keeping them both correct.

3) The arrangements for firing the guns and for observing the of shot.

ommunications.—The positions between which communication st be maintained are the observing positions aloft, the principal trol position, usually in the vicinity of the conning tower, the nsmitting station and the turrets or other gun positions. Com- nications must be rapid and sure, as most of the information sent nly of value at the moment of transmission and loses its signifi- ce if any delay occurs. Hence several lines usually exist between ortant stations, any one of which can be used in the event of akdown of the others. All lines of communication are usually con- trated from outlying stations into the transmitting station. This ion is situated in the centre of the ship, well below the armoured k in the quietest position that can be selected and is the centre he whole control organisation.

oice-pipes are used to a great extent between stations that are manently manned and that are moderately close together. To be ient a voice-pipe must be as straight as possible, and there are l-defined limits of length for each diameter of pipe beyond which acoustic properties are lost. Voice-pipes are difficult to make ertight and gastight.

he telephone is used between all stations, often in addition to the e-pipe. There is usually a telephone exchange, in or near the nsmitting station, solely for the use of the fire control organisation quite independent of the general telephone system of the ship. telephone transmitters and receivers are of many patterns and specially designed for use by operators who have other duties to orm, or who have to use the instruments in positions which are osed to the weather. Electro-mechanical transmitters and re- ers are used for passing ranges, deflection, bearing, orders and er information of a standard character between the control itions and the guns. There are several different patterns of these ruments, those most commonly used in all navies being the Barr troud "step-by-step," and the Vickers "counter" types.

Frequently one transmitter is arranged to work a number of receivers in outlying stations. A development of these instruments is found in the "follow the pointer" method, which is commonly used for sending ranges from the transmitting station to the guns. The transmitter takes the form of a sight dial upon which the range is set by moving a pointer to the required setting. The motion of the pointer is transmitted electrically to pointers upon the gunsights. A mechanical pointer, geared to the mechanism which works the gunsight, is kept in line with the electric pointer by the sightsetter, and the sight is thus kept set without the sightsetter having to watch the movements of a separate instrument. The large clock-faced dials and other similar arrangements which are often seen about the upper works of warships are used for communicating the range and deflection in use to consorts who may be firing at the same target. Their place will doubtless be taken in the future by wireless telegraphy or telephony.

Rangefinding and Rangekeeping.—In the transmitting station are situated the majority of the calculating instruments, and to this position are passed the results of all observations of range, bearing, course of enemy, fall of shot, etc. Also all orders from the chief control officer to the guns are passed through the transmitting station. As a rule the control officer is in direct communication with the officer in charge of the transmitting station by means of a large, direct voice-pipe. The functions of the majority of the instruments in the transmitting station and their details are naturally confidential. Broadly they consist of arrangements for deducing the course and speed of the enemy from such data as may be available, and for calculating from this the rate of change of range and deflection that should be applied to the gunsights. In the British service the Dreyer calculating table is in general use, and to this constant improvements are being made to meet the changed conditions brought about by the increasing range at which the guns are used. The details of this calculating table are secret, but there are other patented apparatus, notably the Argo and the Ford, which aim at achieving the same results. Apart from the calculating apparatus, some form of which is in use in all navies, there are a certain number of instruments which are generally employed.

Rangefinders.—The rangefinder most commonly used by all navies, and which forms the equipment of the British fleet is the Barr & Stroud coincidence instrument. In a capital ship there are at least six large rangefinders, mounted in various positions, and the number and size of the instruments are reduced proportionately in smaller ships. The observations of each instrument are transmitted electrically to the transmitting station, where apparatus exists for obtaining rapidly a mean of all the observations, thus giving what is called the "mean rangefinder range." To this are applied corrections for the density of the air, the effect of wind, the temperature of the charges, the nature of the projectile, the change of range during the flight of the projectile and for several other variables. The result is the gun range which is passed to the guns.

Change of Range Calculators.—To obtain the rate at which the range is changing at any moment involves the solution of two triangles, the functions of which are the course and speed of the firing ship, and the bearing, course and speed of the target ship. The first two of these are known, the third is easily observed, but the other two can only be obtained by calculation, or judged approximately by observation. There are several types of calculators for this purpose, but that used in the British service is the Dumaresque in which the elements are set graphically, and the resulting rate of change of range corresponding to the settings is read off in "yards per minute" which is what is required. The speed of the target ship must always be guessed in the first instance, but instruments known as inclinometers are being experimented with, whereby the angle between the course of the target ship and the line of fire can be observed with fair accuracy at any moment. The course of the target ship is thus obtained.

Range Clocks.—Some type of clock, which can be set to run at the rate at which the range is changing is used in all navies. In the British service the Vickers clock is used. This consists of a powerful clockwork escapement, driving a large pointer around a clock face, the perimeter of which is graduated in yards. A method of altering the speed of the pointer is fitted, so that it can be made to move at speeds of 0 to 2,000 yd. per min. in either direction. Arrangements are made for large corrections in range to be put on the perimeter of the clock without interfering with the motion of the pointer, so that the clock can always be run at the gun range that it is desired to transmit to the guns. There are many other uses to which it can be applied.

Deflection Calculators.—It is a difficult matter to obtain the correct deflection for hitting a target at long range. There are many types of deflection calculators, wherewith, by using the data available in the transmitting room, an approximation to the theoretical deflection can be obtained. All these instruments, however, have their limitations, because, although the allowance can be made for the wind at the firing ship, at long range the wind effect at the target may be entirely different. Also the direction of the wind in the upper air, through which the trajectory of the projectile passes, is an unknown factor. The practice is to calculate the proper setting as near as possible and to correct it by observation of fall of shot. Deflection is of the greatest importance in ranging, for at long ranges, unless the shot fall in line with the target, it is impossible to tell whether they are short or over.

Bearing Indicators.—These instruments are mounted in the control positions, and consist of a bearing plate, mounted with the zero in the fore and aft line of the ship. A telescope or binocular is suitably mounted and the bearing of any object, with reference to the ships fore and aft line, can be readily observed. In the Evershed type used in the British Navy, the bearings are transmitted electrically to the guns and to the transmitting station. This forms a ready method of indicating the correct target to the guns, and from the observations the rate at which the bearing is changing can be obtained.

Observing and Firing the Guns

Before the range at which heavy guns are used at sea became so extended, a single gun was used for ranging, before opening fire with the whole broadside. The differences between the ranging of individual guns, due to wear and a variety of other causes, become accentuated at long ranges, and no two guns can be built that will always shoot precisely the same.

This leads to a "pattern," or spread, resulting when a number of guns of the same size are fired at the same elevation. Apart from this, in practice the errors in laying of the individual gunlayers have to be taken into account. The "spread of the salvo," as it is called, can be reduced by making careful adjustments, but it can never be eliminated entirely, even if there are no errors in laying the guns. The spread can, however, be made an approximately constant quantity, by careful adjustments and training of the personnel, and this quantity is known to the control officer of each individual ship. To base the corrections for the broadside upon the result of the fall of a shot from a single gun is obviously liable to lead to large errors, and at extreme ranges the splash of a single shot is extremely difficult to see.

It is now the general practice to range with a salvo of several guns, usually half the broadside, and to continue firing alternate salvoes of an equal number of guns. The object of the control officer, knowing the approximate spread of his salvoes, is to give such corrections, using some form of bracket system, as will bring the mean point of impact of the salvo on to the target. This is termed a straddle—that is, some shots short and some over, and when this is achieved, the control officer knows that he is obtaining the maximum hitting effect from the armament that he is controlling.

Director Firing.—Practically all navies have now adopted some form of master sight or director, whereby all guns can be fired by a single layer. This system of firing has many advantages, chief amongst which are the elimination of smoke interference between the guns; the reduction in personal errors in laying; and the fact that it is far easier to spot the fall of a salvo that falls "all together" instead of being spread out over an irregular time interval.

In the British Navy the director installation invented by Adml. Sir P. Scott is used. This consists of a director sight mounted aloft, or in a director tower well separated from the guns themselves. The sight is similar to a gunsight and is carried in a mounting which can be trained and elevated in the same way as a gun mounting. The motion of the director mounting is transmitted electrically to training and elevation receivers at the guns. On these receivers are mechanical pointers geared to the training and elevating gear of the turret or gun. The gun is moved in training and elevation so that the mechanical pointers are kept in line with the electric ones worked by the director mounting. The guns thus follow the motions of the director or master sight and are laid at the desired elevation and training. The gun range and deflection are set upon the director sight, and the director telescope is laid upon the target in the same manner as a gunsight. The firing circuits of all guns are brought to a single trigger at the director sight, so that all guns can be fired simultaneously by the director layer.

This brief description indicates the principle upon which the director is worked, but in actual practice there are many complications. Corrections have to be made for the relative positions and levels of the different gun mountings and the director sight and for many other matters. The installation is intricate, but has stood the test of prolonged war service and the results achieved by it have been invaluable. In capital ships there are, as a rule, two director sights, one mounted aloft and one just above the level of the guns, which can be used alternatively for the main armament. A director is also fitted for use with the secondary armament. Light cruisers are fitted with directors for th main armament, and a modified form is used in destroyers.

Squadron Control.—In the foregoing, the control of the fire the guns of a single ship has been dealt with, but under mod battle conditions, it often happens that one or more ships engage the same target. When this occurs, unless there is so pre-arranged organisation between the firing ships, confus will occur owing to the spotting officer taking the fall of anot ship's salvoes for his own. Therefore a pair of ships firing at same target generally fire a salvo or pair of salvoes alterna each waiting upon the other and correcting the gun range by fall of the other's salvoes. This necessitates an intimate int communication between the two control officers, which is possi by wireless telegraphy.

A squadron of four ships may fire together at the same targ the fire being controlled by the control officer of the leader, orders the gun range at which each ship shall fire, after receiv the result of observations as to fall of shot from his own the firing ship's spotting officers, and possibly from the air. I case such as this, the object of the squadron control office the same as that of the control officer of a single ship, that is bring the mean point of impact of the shell from the armam he is controlling as near the target as possible, for then o can he be sure that he is getting the maximum hitting effect. view of the extreme ranges at which future actions at sea will fought, it appears certain that fire tactics will tend to develo the direction of concentrated fire by pairs of ships or by squ rons, aided by observation from the air. The perfecting of intricate organisation of the fire control of any ship is the m important item in making her an efficient fighting unit requires arduous and painstaking exercise lasting over ma months. (*See* ORDNANCE.) (S. H. W.

GUNPOWDER: *see* EXPLOSIVES.

GWALIOR, MAHDO RAO SINDHIA, MAHARAJA OF (18 1925), was born Oct. 20 1876, and succeeded his father, Jayaji Rao Sindhia, in 1886 (*see* 12.748). He threw him with the utmost keenness into the supervision of every detai state management, endowing Gwalior with an excellent system light railways, carrying out irrigation projects, husbanding revenues and raising the standards of administration by unc ing vigilance. In the World War his two regiments and trans corps fought with distinction in France, East Africa, Egy Palestine and Mesopotamia. A boundless and inventive g erosity found scope in his constant presentation of munition war and princely donations to various relief funds. He took main part in purchasing, equipping and maintaining the hosp ship "Loyalty," which carried 15,000 war patients; and provi a convalescent home at Nairobi in East Africa—to mention c a few of his gifts. A lieutenant-general in the British Army was Hon. A.D.C. to King George V., and the bearer of sev Grand Crosses; his permanent dynastic salute was raised to maximum of 21 guns, and Oxford and Cambridge confe honorary degrees upon him. King George V. also honoured by becoming sponsor to his heir, George Jivaji Rao (b. 19 The Maharaja went to Europe in the spring of 1925, partly recuperate his impaired health, but died in Paris on June 5.

GYMNASTICS (*see* 12.752).—This form of athletic sports changed little since 1910. The undoubted influence of the revi Olympic Games upon the modern development of athletic sp and exercises has not greatly affected gymnastics, perhaps cause of the already high state of efficiency reached prior to revival. The International Gymnastic Federation, which but one affiliated nation outside Europe, *i.e.*, the United Sta was founded in 1881, and 20th-century efforts have tended rat to consolidation and perfection than to extension and progr One important feature was the foundation, in 1923, of an In national Federation for the promotion of the educative, ins of the executive, branch of the art. Both federations have t British affiliations, that to the Fédération Internationale Gymnastique being the Amateur Gymnastic Ass'n and tha the Fédération Internationale de Gymnastique Educative b the Ling Association.

'he enormous development of athletic sports throughout most he European countries has not caused gymnastics to suffer; great festivals at Nuremberg, Leipzig, Frankfort and in den, France and Switzerland continue to attract thousands gymnasts. On the continent of Europe the movement is ional: in Great Britain, and to a lesser extent in the United tes, interest in gymnastics is individual. The repetitive char- er, the absence of the competitive spirit, perhaps also the ective discipline so necessary, appear to have too little in mon with the Anglo-Saxon character for gymnastics ever rouse the enthusiasm which prevails in the European coun- s. The inclusion of gymnastic competitions at the Olympic nes has not appreciably affected the situation. (*See* ATH- ICS; OLYMPIC GAMES.) (P. Lo.)

YNAECOLOGY: *see* WOMEN, DISEASES OF.

YROSCOPE (*see* 12.769).— This instrument has rapidly be- ie of technical and commercial importance after having been irded as little more than a toy or means for use in demon- iting the dynamics of solid bodies. The developments in its struction and application, since torpedoes, submarines and oplanes came into extensive use, have been numerous. In- tive efforts in connection with it were greatest about the r 1920. From a commercial standpoint, the successful appli- ion of the gyroscope in the arts has led to the establishment of oortant industries turning out gyroscopic appliances with ors weighing up to about 90 tons.

mprovements in Construction.—Since 1910 many improvements e been made in the construction of the gyroscope and its modifica- ı, the gyrostat, independently of accessories for rendering them ful in the arts. Messrs. Gray and Burnside's gyrostat, designed efly for experimental purposes, is essentially a direct current tric motor, the rotor of which, in the form of a Gramme ring ıred between the peripheral parts of two magnalium disks, serves he wheel or rotor of the gyrostat. The field magnet and brush r are within the space between the disks, and the commutator is ıred to the inner side of one of the disks. The rotor, made up of heavy ring, the very light disks and the commutator, is mounted ı stationary shaft and may be driven at a speed of 25,000 revolu- ıs per minute. Enclosed in a magnalium casing, the whole forms ompact, portable apparatus.

n Rutt's gyroscope, the relative arrangements of the parts is ersed, so as to leave the rim of the rotor entirely free, the rotor ng mounted adjustably on a central gimbal carried by a rotary ft.

t is important that the rotor of a gyroscope should be mounted in urately adjusted bearings, especially when the rotor is spun at a h velocity. In order to satisfy this requirement, when ball bear- s are used, Messrs. Griffin and Sons, Ltd., mount the rotor on a ular spindle encircling a screwed rod secured within the Cardan g carrying the rotor; the ends of the spindle rotate against ball rings held in correct position by adjustable sleeves on the rod. e spindle and rod are concentric but do not touch each other. e rotors of many gyros are rotated in a partial vacuum to reduce tional resistance. In order to minimize the resistance and at the ne time keep the interior of the gyro casing cool, Messrs. Anschütz, ır Kiel, circulate hydrogen, helium or other light gas through the ing.

Gyrostatic Horizon.—On ships, aeroplanes, etc., where the use a mercury bath for obtaining an artificial horizon is often im- acticable, one of the methods adopted is to employ a gyrostat th its spinning axis vertical and carrying a plane reflector at ht angles to that axis. This, the first practical use of the gyro, s introduced by M. Serson in 1774.

ince 1910, several forms of this type of apparatus have been signed. Fig. 1 shows the main features of the gyrostatic horizon Messrs. Anschütz & Co. A box *a* is mounted on knife edges by a pension differing from the ordinary Cardan in that the horizontal e joining the knife edges *b*, which directly supports the box, is ow that joining the knife edges which support the outer ring, both es being higher than the centre of gravity of the box and its achments. Within the box is the rotor *c* supported by ball bear- s *d*, *e* and rotated by any suitable motor. A rotary ring *f* carries adjustable weight *g*, by means of which the centre of gravity of whole is moved out of the gyroscopic axis so that this axis is con- ained to precess in such a way as to compensate for the effects of earth's rotation; by means of a scale, graduated in degrees of itude, the weight can be adjusted correctly. An annular vessel containing mercury or oil, and formed with perforated partitions, employed for damping precessional movements of the gyro.

Gyro-compass.—This instrument of precision is used in the rious navies of the world, and in the mercantile marine; it is used extensively in submarines, for which the magnetic compass is unsuitable. A gyro-wheel, mounted to rotate rapidly about an axis free to turn in any direction, but provided with a form of gravity control, limiting its tilting movement, tends to set itself so that its axis points in the direction of the true north. This represents the working of the principle on which the construction of the gyro-compass depends. The many forms of gyro-compass which have been patented differ mainly in the construction of their gravity control.

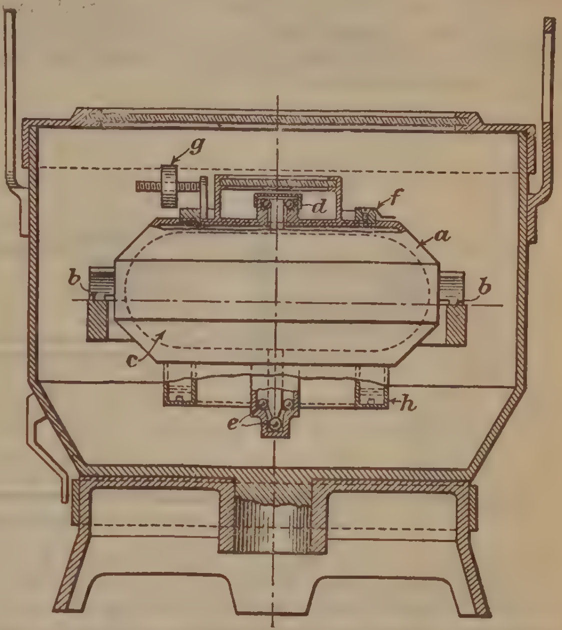

FIG. 1. Diagram showing the main features of the gyrostatic horizon of Messrs. Anschütz & Co.

In 1852 Foucault used a gyro apparatus to demonstrate the earth's rotation; this was the first practical step towards the production of the gyro-compass. A form of gyro-compass, constructed by Sir W. Thomson (afterwards Lord Kelvin) was exhibited in 1884. In the early part of this century the increasing use of submarines demanded the provision of a compass unaffected by magnetic conditions, and Dr. Anschütz invented a gyro-compass in which the rotor and its casing were mounted in a support floating in mercury, thus limiting movement about a horizontal axis. This compass was unreliable when the ship was rolling, and, to overcome this defect, Messrs. Anschütz & Co. introduced, in 1912, an apparatus comprising three gyros, two of which eliminated errors due to rolling. This apparatus was used in the German navy.

In the gyro-compass of The Sperry Gyroscope Co., of New York (British patent specifications, Nos. 15669 of 1911 and 135500), the gyro-wheel casing is supported by a suspended wire, any twist of which caused during the working of the compass is taken out by a follow-up mechanism of special construction. The Sperry Co.'s compass was adopted for use in the British and Allied navies, and was improved by Messrs. Harrison and Rawlings, who introduced a mercury control attachment (British patent specification, No. 131987).

The suspension of the vertical axis in the Brown gyro-compass (British patent specification, No. 124529) is provided by a pulsating column of oil under great pressure. In Henderson's gyro-compass (British patent specification, No. 166570) the gyroscope has its centre of gravity and that of its gravity-control apparatus at its centre of suspension, and relative motion between the gyro and gravity control is arranged to produce a controlling couple.

Gyro-apparatus for Stabilising Wheeled Vehicles.—About the year 1905, Mr. L. Brennan, of Gillingham, introduced his monorail car, in one form of which he employed two gyrostats rotating in opposite directions and mounted in a horizontally pivoted frame. The gyrostats were geared together so as to rotate in opposite directions; one was provided with means for automatically accelerating the precession when the car swayed to one side, thus effecting stabilisation, in accordance with Lord Kelvin's rule that acceleration of the precession causes the gyro to rise against gravity. In 1909, Mr. Brennan introduced powerful mechanism to control the precessional movements or to alter the position of the centre of gravity of the car, *e.g.*, by sliding the car body on the under-carriage.

The car was generally unreliable when running rapidly round sharp curves, and its gyro bearings were liable to overheating. Several of the cars were exhibited at different times; a large one was run at the Brennan factory, on Nov. 10 1909. This car had two bogies, each with two double-flanged wheels. The rotors, 15 cwt. each, were rotated at a speed of 3,000 r.p.m.; the gyros were encased and in a partial vacuum. At a speed of about 7 m. an hour, the car travelled satisfactorily on a curved track and could travel on gradients up to 1 in 13.

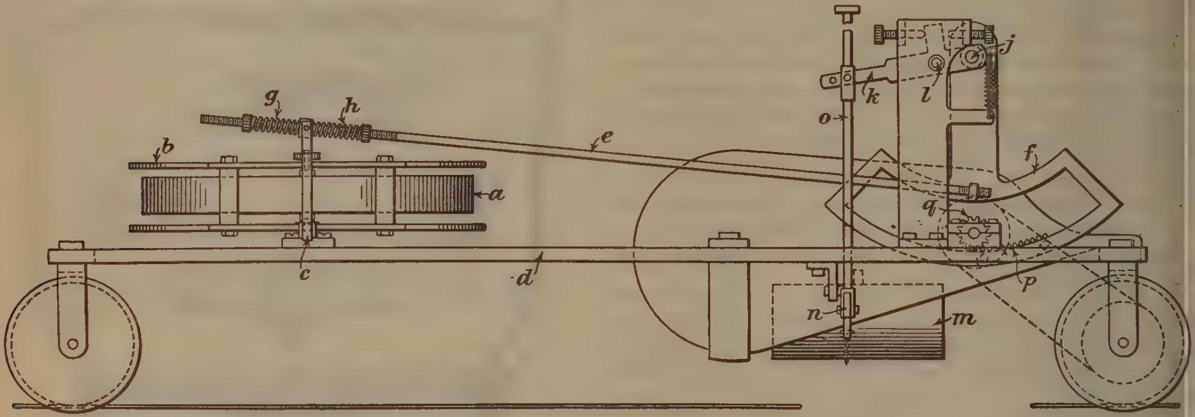

FIG. 2.—Diagram showing principal parts of P. Schilowsky's Auto-car.

The monorail car of R. Scherl, of Dresden, had one or more gyrostats with their rotors on vertical axes and mounted so as to be in unstable equilibrium and positively connected to the car at every moment. Scherl's car was not successful, difficulties having been experienced on inclines and when running round curves to right and left.

In the auto-car of P. Schilowsky, described in British patent specifications, Nos. 12021 of 1909 and 941 of 1914, the gyrostat, like Scherl's, is unstable. Fig. 2 shows diagrammatically the principal parts of the car. The rotor *a* is mounted in a frame *b* supported by pivots c^1, one at each side of the car frame *d*. A rod *e* connects the gyro to a quadrant *f*; this rod is encircled by adjustable springs *g*, h^1, to obtain a yielding connection. The quadrant *f* is suspended at j^2 from a lever *k*, fulcrummed at l^1 and caused to oscillate by the action of a pendulum *m*; the pendulum is pivoted to the car frame and presses against a cord which extends from a fixed part of the frame over a pulley and then beneath the pendulum, on its way to one arm of a bell-crank lever *n*; this is connected to a rod *o*, which rocks the lever *k*.

When the pendulum presses against the cord, as a result of the tilting of the car to one side, the quadrant *f* is lifted and a rack p^1 on the quadrant engages with a rotating pinion q^1; consequently, pressure is applied by the rod *e* to the gyro mounting with the result that its oscillations are annulled and the car brought into an upright position. Although only one pendulum is shown in fig. 2, the auto-car had two pendulums to enable the car to reverse and take curves to right and left. The inventor, in 1914, made trial runs in cars of this type and met with much success. Claiming that a monorail system of transport would be quicker and cheaper than the existing systems, Messrs. Scherl and Schilowsky, at different times, have considered plans for laying down extensive networks of lines, especially in Germany, but nothing seems to have been done.

Dr. J. G. Gray, of Glasgow University, has designed a two-wheel car controlled gyroscopically. This car has a front and a rear compartment, each running on a wheel and connected together by a vertical swivel-joint. The front compartment carries a gyrostat mounted in fixed lateral bearings and the rotor is spun in the vertical plane containing the wheel base. A motor for driving the car is installed in the rear compartment. A car of this kind was shown at a meeting of the Inst. of Civil Engineers, on June 17 1925. The car was driven forwards and the gyro rotor was spinning clockwise as seen from the left-hand side of the car, but when the car swayed to one side the two compartments were thrown out of line. Then, in consequence of the propulsion by the rear compartment, an acceleration of the gyroscopic precession was effected and the car was brought back to the upright position.

Gyroscopic Apparatus for Stabilising Ships.—The earliest u
of the gyro principle for stabilising ships was made by E.
Schlick, of Hamburg, in 1903. He mounted a number of gy
stats in the ship and used, for eliminating precessional motio
a braking-mechanism exerting a constant pressure on the gy
mountings. His invention was improved by Messrs. Swa
Hunter and Wigham-Richardson by using spring-controlled
floating bearings for the gyro frames and regulating the braki
effect in accordance with the degree of rolling of the ship.

The gyroscopic apparatus of E. A. Sperry and The Sper
Gyroscope Co., of New York, is of an active kind, for its acti
is not limited by the rolling of the ship but may itself impart
the ship a rolling motion so that the ship may be listed and he
up to the full strength of the gyro apparatus installed. Co
trolled in this way, the ship may be extricated from a diffic
position, may be used as an ice-breaker or, as set out in Briti
patent specification, No. 149439, a rolling motion of predete
mined magnitude may be maintained in a warship while her gu
are being fired.

The important elements of a Sperry stabiliser are the main gy
the small control gyro, the precession engine and the system
electric circuits. The main gyro may have its spinning axis verti
and is so mounted that a precession can be imparted to it by mea
of a circular rack which engages with a pinion of the precession e
gine. The control gyro, spinning on a horizontal axis, is so sensiti
that it precesses as soon as the ship begins to roll and effects t
closing of an electric contact which, by means of relay switch
operates the precession engine, thus bringing into action a power
stabilising couple. Next, the control gyro stops the precession eng
and is ready to deal with the next wave impulse.

Among the stabilisers built by The Sperry Gyroscope Co. is th
for the liner "Huron" of 18,000 tons displacement. A large bic
ical casing encloses the main gyro in a partial vacuum and the gy
wheel, made by bolting together two disks each 13 ft. diam., weig
about 100,000 pounds.

In the stabilising apparatus of Sir J. B. Henderson, of the Ro
Naval College, Greenwich, the velocity of the gyroscopic precessi
is controlled wholly by means of a single mechanism, which may
a continuously variable speed-gear of the variable-stroke pump ty
of the mechanical type or of the viscous resistance type. Fig
shows the mounting of a gyroscope and its hydraulic connectio
with the ship and fig. 4 a controlling means comprising a variab
stroke pump.

The rotor casing *a* is mounted on trunnions *b* in the Cardan ring
which is carried by trunnions *d* supported by standards *e*, bolted
the deck so that the trunnion axis *d* extends fore and aft. The rin
is connected by rods *f* to the buckets *g* of the single acting pum
h, *j*, which have suction valves *k* and spring-controlled delive
valves *l*; the suction pipes *m* and delivery pipes *n* may lead to t
sea far below the water line. When a wave strikes the ship, t
pressure in one of the pumps *h*, *j* increases at once and tends to fo
the gyro to roll with the ship. The hydraulic cylinders *o*, *p* of
precession-control apparatus are mounted on the ring *c* and th
plungers *q*, *r* are connected to a crank *s*, fixed to the trunnion *b*
the gyro case. In order to prevent the ship from rolling, the veloci
of the plungers *q*, *r* should be proportional to the difference of pr
sure in the cylinders *h*, *j* and the ratio between them must have
certain value. To effect this, the cylinders *o*, *p* are respectively co
nected by pipes *t*, *u* to the cylinder of a variable-stroke pump *v*, t

ton of which is connected to a spring-controlled piston *w*, working ı cylinder *x*; the ends of this cylinder communicate with the pumps nd *j* respectively, by means of pipes *y*, *z*.

n a gyro apparatus designed by the Tokio firm, Mitsubishi sen Kaisha, the precessional movements of one or more ostats effect the closing of electrical circuits controlling an engine ich is geared up to rotary retractile fins projecting from the ship's ge.

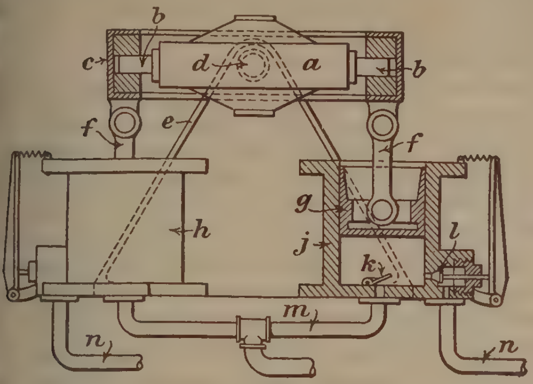

Fig. 3.

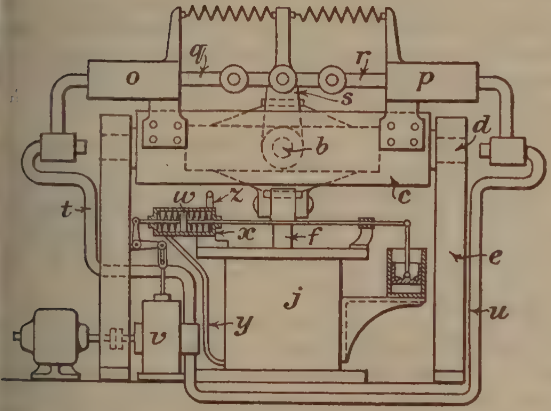

Fig. 4.

Fig. 3.—Diagram showing the mounting of a gyroscope, and its draulic connections with the ship; and Fig. 4, a controlling means mprising a variable stroke pump.

Gyro-stabilisers for Aircraft.—One of the more recent of these abilisers is The Sperry Gyroscope Co.'s, which has two pairs oppositely rotating gyrostats, with their precession axes vercal, mounted in a Cardan suspension, the outer ring of which as its pivots above the centre of gravity of the gyro-apparatus. he lateral and longitudinal balancing planes of the aeroplane e respectively actuated by relative displacements between the yro-apparatus and two control arms carried on the aeroplane. These arms control the working of a motor which adjusts the planes. A still more recent stabiliser, that of the Société Anonyme des Établissements Marmonier Fils, comprises two gyros mounted in an elongated frame supported by horizontal pivots, each gyro carrying a pendulum bob. The rotors spin in a horizontal plane and in opposite directions with equal velocities.

Gyro-steering Apparatus for Torpedoes.—Since 1910, improvements have been mainly in details in connection with the driving of the gyro-rotor, its locking and releasing mechanism, or the arrangement of the gyro-apparatus to minimise the effects of rolling of the torpedo.

Gyro Turn-indicators.—In a form developed at Farnborough, the rotor was mounted outside the aeroplane and driven by the wind, the rotation being in a vertical plane at right angles to the direction of flight. The direction and rate of turn was indicated by a precession-actuated pointer. In the Reid control indicator, a compact combination of gyro-turn-indicator, airspeed indicator and clinometer, manufactured by Messrs. Vickers, Ltd., the rotor of the turn-indicator is driven by a jet of air passing through a compound Venturi tube placed in the slip stream of the propeller. The turn is indicated by means of precession-actuated electric contacts, which switch on one, two or more green lamps, if the turn is to the right, or one, two or more red lamps, if the turn is to the left; the number of lamps switched on is directly proportional to the rate of turn (*see* AIR NAVIGATION).

Gyro-apparatus for Indicating Rate of Angular Motion.—This is usually employed for recording the rolling motions of a ship. In the Cunard liner "Laconia," fitted with Frahm's anti-rolling tanks, a gyro pendulum was used for recording the rolling motions. Its rotor was horizontal and driven by an electric motor; the rotor was mounted in a Cardan ring suspended in a stand secured to the deck, the pivots of suspension being fore and aft. The angular motion of the stand relatively to the gyro represents the rolling of the ship and is recorded by a pencil beneath which a paper band travels continuously.

Gyroscopic Transmission Gear.—The gyro principle has been utilised in transmitting power, the gyro serving as a flexible connection between a driving and a driven shaft. (*See* VARIABLE TRANSMISSION GEAR.)

Other Applications.—In apparatus for measuring deviations of bore-holes from the vertical, the gyroscope has been employed to compensate for rotation, in the bore-hole, of the outer casing containing the measuring apparatus. Messrs. Krupp's fire control apparatus for use with naval guns makes use of a gyrostatic apparatus at the observation station and a precisely similar apparatus at the gun station, both apparatuses being connected electrically so as to operate strictly in unison. The gyroscopically controlled photographic camera of Prof. Sir J. B. Henderson comprises a gyro-controlled prism for counteracting the effects of lateral movements and pitching of the support and a gyroscopically rotated sensitive plate to compensate for rolling movements. The camera is intended chiefly for aerial photography and is rigidly secured to an aeroplane.

(T. E. L.)

HAAG, CARL (1820–1915), British painter (*see* 12.780), died at Rother Thurm, Oberwesel, Germany, Jan. 17 1915.

HAASE, FRIEDRICH (1827–1911), German actor (*see* 12.782), died in Berlin March 17 1911.

HAASE, HUGO (1863–1919), German politician, was born Sept. 29 1863, at Allenstein in East Prussia. At the outbreak of the World War he was parliamentary leader of the Social Democratic party in the Reichstag, but in 1916 he seceded with the Independent Socialists, who refused to vote the estimate and war credits, and became their leader. In this capacity he exercised a moderating influence upon the extreme section of the Independents, who at a later date (1920) joined the Communists. He was one of the commission of six who conducted the Government of the German Reich, in the name of the people, immediately after the revolution of Nov. 1918. Haase died on Nov. 7 1919 from wounds received in an attempt upon his life while he was entering the Reichstag building.

HABER, FRITZ (1868–), German chemist, was born in Breslau Dec. 9 1868. He studied at the universities of Berlin and Heidelberg and at the technical high schools at Charlottenburg and Carlsruhe. He was then appointed staff professor at Berlin University and afterwards became director of the Kaiser Wilhelm Institute for physical chemistry and electrochemistry. He made a special study of thermodynamic technical gas reactions, and also made experiments in connection with the equilibrium of ammonia and the influence of very high pressures and high temperatures. During the World War he studied the gases used in warfare and their effective frustration by gas masks and chemical means. He conducted particularly important researches in collaboration with Bosch, which led to the establishment of the Haber-Bosch process for the production of nitrogen manure. After the War the large works at Leuna, near Halle, produced more nitrogenous manure, according to this process, than was imported previously in the form of nitrate of soda. The chief characteristic of the process is the continuous reaction under a pressure of 200 atmospheres, and the most important raw material used is water gas, produced from coke and gypsum (*see* NITROGEN, FIXATION OF). His recent works include *Beitrag zur Kenntnis der Metalle* (1919); *Über die Synthese des Ammoniaks: Die Chemie im Kriege* (1922); *Fünf Vorträge aus den Jahren 1920–3: Über die Herstellung des Ammoniaks aus Stickstoff und Wasserstoff* (1924).

HABITUAL OFFENDERS.—In the law, as in common parlance, a habitual offender is one who is repeatedly guilty of criminal offences, who makes a business of crime. In this broad sense the term is identical in meaning with recidivist, a constant backslider. In a more restricted and accurate sense, however, habitual offender denotes one who has become a recidivist by force of habit, and this opens up a wide and interesting divergence of opinion among psychologists as to the mainsprings of conduct. One school of students of this science stresses the hereditary element in human nature—instinct, impulse, the innate characteristics—and to the most extreme of these every " true " criminal is by propensity if not in act, a recidivist. The criminal is born, not made. The other school, believing that our original endowment differs only in degree and not in kind, lays the emphasis on environment, the individual's experience of life. The criminal is the product of circumstances.

The Schools of Thought.—Without drawing too fine a line between the adherents of these two schools of thought, it may safely be asserted that the medical criminologists tend to align themselves with the former and the sociological criminologists with the latter. Many psychiatrists have committed themselves to the view that all recidivists, if not all criminals, are either insane or psychopathic personalities. There is, on the other hand, a strong current of psychological thought in evidence at the present time, which strongly supports the view expressed in the popular maxim, " man is a creature of habit." Habit is not only a manner of acting but of thinking and feeling as well. Will, co science, impulse, are all the fruits of habit. Indeed they *are* th habit of which the external act or conduct is only the expressio The habitual offender is what he is because his experience of li has been such as to cultivate criminalistic ways of thinkin feeling and acting.

Probably no one would deny that the development of the anti-social tendencies comes easier to some than to others, but t clear implication of this doctrine is that, given a sufficiently e environment, no man that is born of woman is so endowed b nature as to resist its moulding influence. On the other hand is conceded that some, probably a very small proportion of t whole, are born into the world with such a defective equipme as to render them very unlikely subjects for the development a socially useful character. Such are the neurotic individua who early in life develop into insane or psychopathic persona ties. The notion, current a few years ago, that the feeble-minde are of this sort, has now been generally abandoned. Mental defe is a handicap in leading any kind of life, good or bad, but involves no predisposition towards the latter. The net result that the good life is not an individual endowment but a soci achievement, and the same is true of the evil life.

That the habitual offender is not irredeemable appears to ha been demonstrated by the experience of Camp Hill in Englan and by fortunate periods in the recent history of Sing Sing a Auburn prisons in the United States. " Habit is second nature but like the original nature, it is still plastic and susceptible new and more wholesome influences.

BIBLIOGRAPHY.—The literature of the subject is still, for the mo part, to be found in psychologic and other periodicals. Books articles that may be read with profit are:

Glueck, " A Study of 608 Admissions to Sing Sing Prison in *Mental Hygiene*, 2 (1918); " Jack " Black, " Breaking the Sha les," *The Call* (San Francisco, 1918, 1926). (G. W. K.*

HABSBURG (*see* 12.787), the former ruling dynasty of th Austro-Hungarian Empire. The Habsburgs' relations with the subjects were defined in the 18th century, when Charles VI last of the Habsburgs proper, issued the pragmatic sanctio which was accepted by the estates of his peoples. The fam dominions were hereby declared indivisible, and the descendan of Charles were accepted as their hereditary rulers in perpetuit so long as a male or female member of them remained. Th dynasty of Habsburg-Lorraine, founded by Charles's daughte Maria Theresa, and her husband Francis I., ruled in virtue this contract. In 1918 there were over 120 archdukes or ar duchesses, descendants of Maria Theresa, who could thus su ceed to the throne.

Results of the War.—Charles I. (*q.v.*), the last ruling Empero Austria and King of Hungary, succeeded his great-uncle Nov. 21 1916. At this time his subjects still protested loyalty the dynasty; but during the collapse of Oct. 1918 one nati after another repudiated its rule. The Poles of Galicia, who ha long been practically independent, formed a national council Cracow on Oct. 28 1918 and soon after adhered to the republ of Poland. The Ruthenians of East Galicia decided on Oct. to form a separate state. The Czechoslovaks on Oct. 21, in manifesto dated the 18th, declared themselves independent a expressly repudiated Habsburg rule. The Yugoslavs made ve similar proclamations during the last days of October. On Oc 27 Count Andrássy, the Austro-Hungarian Foreign Ministe accepted President Wilson's demands " regarding the rights the peoples of Austria-Hungary, particularly those of t Czechoslovaks and Yugoslavs." The states of Poland, Yug slavia and Czechoslovakia soon after came formally into bein and although Charles never renounced his sovereign rights these territories, the Habsburg family has made no serious clai to reassert them; although a small monarchist party in Croat since toyed with the idea of reuniting with Hungary under bsburg rule. The treaties of Saint Germain and Trianon petuated the boundaries of these States, and confirmed Italy l Rumania in the possession of their parts of the former bsburg monarchy. Most of the treaties of the "Little tente" (*q.v.*) are expressly directed towards the maintenance these frontiers, especially those of Hungary, and thus im- itly (the forms of those states being what they are) to the lusion of the Habsburgs from these territories.

Position of the Emperor Charles.—There remained only rman-Austria and Hungary. On Nov. 11 1918 Charles issued roclamation in which he stated:

> till, as ever, filled with unchanging love towards all my peoples, ill not oppose my person as an obstacle to their free development. ecognise in advance the decision which German-Austria will take its future form of State. The people has assumed the government ough its representatives. I renounce any share in the affairs of te. At the same time I remove my Austrian Govt. from its ce.

The Provisional Govt. of German-Austria proclaimed a ublic on the following day. On March 12 1919, following elections, the first national assembly repeated this declara- n. Charles, however, refused to abdicate in his own name and t of his dynasty. Thereupon the national assembly, by decree April 2 1919, banished all Habsburgs from Austria and con- cated the family property for the benefit of the War invalids. bsburgs who renounced all rights other than those of private izens were, however, allowed to live unmolested in Austria, d several of them did so. The legitimist movement in Austria s been very weak since these events. Vienna is almost fanati- ly republican, and even in the provinces, the monarchist move- nt in favour of the Wittelsbach dynasty has been quite as ong as the legitimist Habsburg movement. Austrian repub- ans claim that Charles's acceptance in advance of the republic s equivalent to a renunciation of the throne.

Charles and Hungary.—Charles issued a similar proclamation Hungary on Nov. 13 which Karolyi answered by proclaiming e Hungarian Republic on Nov. 16. When, however, the ght regained power in Hungary after Karolyi's and Kun's gimes, it proceeded by Act I. of 1920 to abolish all legislation ssed by these two Governments. Hungary, therefore, reverted the status of a kingdom, and controversy arose whether or not arles's action has annulled the pragmatic sanction, in which se the monarchy in Hungary, under her old constitution, was ctive or not. "Legitimists" and "free electors" disagreed lently, the latter usually demanding the election of a Habs- rg but one whose person and wife should be more popular an those of Charles.

On Feb. 2 1920, during the discussions on the draft treaty of ianon, the Allied and Associated Powers declared that a absburg restoration in Hungary would be a matter of inter- tional concern and that they would neither recognise nor lerate such a restoration. They attempted to insist on Hun- ry's styling herself a republic, but finally, in view of the jections raised by the Hungarian delegation, compromised on e word "Hungary."

Charles returned to Hungary and attempted to assert his im on March 27 and Oct. 20 1921 (*see* HUNGARY). On April 4 e Conference of Ambassadors insisted that Charles should ve Hungary. After the second coup, under pressure from e Powers and the Little Entente, the Hungarian Parliament ssed a decree (Nov. 3 1921) whereby the sovereign rights of arles and the pragmatic sanction were declared forever rogated and the right of the Hungarian nation to elect its king free choice restored. On Nov. 10 Hungary addressed a note the Powers consenting only to elect its king in agreement th the Powers and accepting the notes of Feb. 2 and April 3 21. The Legitimist party, however, still looks on Otto as the gitimate king since Charles's death on April 1 1922. Otto and s mother share this view.

Habsburgs are scattered over Europe. Most reside in Hun- ry, Austria and at the Spanish Court. Their financial position various. They have lost all valuables and estates owned in virtue of their rank. Great controversy was aroused by the fact that Charles took with him, and sold, the crown jewels. Many of the family, however, as the Modena and d'Este branch, own vast private fortunes and great estates. The Hungarian branch was fortunate in this respect, as their wealth was not touched by the non-socialist Government. The Polish Govt. at first sequestrated Habsburg estates, but afterwards released them. Austria confiscated all estates, etc., that were not purely private property. The income of the senior branch of the family is small.

The Archdukes.—The remaining Habsburgs have not been prominent outside the realms of politics. The Archduke Frederick (b. 1856) became inspector-general to the Austro-Hungarian army after the murder of the Archduke Francis Ferdinand (*q.v.*) in June 1914. His command was only nominal, his chief of staff, Conrad von Hötzendorf, performing the real duties. In 1917 the Emperor Charles took his place. The Archduke Eugen (b. 1863) also held a high command, assisted by Gen. Krauss. The Archduke Joseph (b. 1872) resided in Hungary, where he enjoyed great popularity. During the World War he commanded a division, and later an Army Corps. At the debâcle he assumed a nationalist Hungarian attitude, recalled the Hungarian troops under his command from the front and acted as intermediary between the King and Karolyi's Government. While Karolyi still took the oath of loyalty to King Charles, Joseph had already repudiated the monarchy and his own title. He lived quietly on his own estate as "Joseph Habsburg" throughout the Commune; but after its fall, he assumed power on Aug. 6 1919 as administrator of Hungary. He was forced to retire on Aug. 22, as the Entente declared that they would not negotiate with Hungary under a Habsburg and were "obliged to insist upon the present pretender to supreme power in the Hungarian State resigning." After this time Joseph took little part in public life.

The Archduke Albert (b.1897), son of Archduke Frederick supported by his wife, Isabella, became the chief candidate of the "free Electoral party" in Hungary, with whom he had close relations. The Archduke Stephen (b. 1860), whose estates were in Galicia, was put forward as a candidate by the Polish monarchist party. His son, the Archduke William (b. 1895), at one time aspired to the throne of the Ukraine. Although many archdukes, including Frederick and Francis Ferdinand, were known as collectors, the Habsburgs have not been prominent as creative artists. Archduke Leopold Wölfling wrote a book entitled *Habsburger unter sich.* (*See* AUSTRIA.) (C. A. M.)

HADFIELD, SIR ROBERT ABBOTT, (1859–), British metallurgist, was born in Sheffield Nov. 29 1859. Educated at Sheffield Collegiate School, at an early age he interested himself in metallurgy, subsequently becoming chairman of Hadfields, Ltd., Hecla and East Hecla Works, Sheffield, and director of other important companies. In 1883 he patented his process for the production of manganese steel (*see* 14.809) and became famous as the inventor and improver of various metallurgical processes, including low hysteresis steel and many other special ferrous alloys. He became a member of many scientific committees, and was president of the Iron and Steel Institute (1905–7), of the Faraday Society (1914–20), and of the Society of British Gas Industries (1917–8), besides being master cutler of Sheffield 1899–1900. In 1908 he was knighted; the following year became F.R.S., and was created a baronet in 1917. Sir Robert received many honours, including 10 gold medals, from scientific and learned societies; and became corresponding member of the French Academy of Sciences; hon. member of the Royal Swedish Academy of Sciences; and officer of the Legion of Honour. He published over 160 scientific and technical papers of considerable importance. His book *Metallurgy and Its Influence on Modern Progress* is a standard work of reference.

HADLEY, ARTHUR TWINING (1856–), American economist and educationalist (*see* 12.798), was elected a director of the New York, New Haven and Hartford Railway in 1913. In 1914 he lectured at the University of Oxford on "Institutions of the United States." In 1915 he endorsed college military camps and advocated the counting of military training for a degree.

In 1920 he resigned as president of Yale University and the same year was elected a director of the Atchison, Topeka and Santa Fé Railway. He wrote *The Moral Basis of Democracy* (1919) and *Economic Problems of Democracy* (1923).

HADLEY, HENRY KIMBALL (1871–), American composer, was born at Somerville, Mass., Dec. 20 1871. He studied theory and composition under Emory and Chadwick in Boston, completing his studies in Vienna. In 1904 he went to Germany, where he was Kapellmeister in Mainz Opera House for two seasons, and produced his opera *Sofie* in 1909. Returning to the United States in the same year, he was conductor of the Seattle Symphony Orchestra until 1911, and of the San Francisco Symphony Orchestra 1911–5. In 1921 he became associate conductor of the N. Y. Philharmonic Orchestra. He produced three grand operas: *Azora* (Chicago Opera Co.), *Bianca* (Society of American Singers) and *Cleopatra's Night* (Metropolitan Opera House). He composed also ode-music for the Worcester (Mass.) Festival (60th Anniversary) and *Resurgam* for the Cincinnati Festival, 1923, in addition to four symphonies, overtures and cantatas, three tone poems, ballet suites and over 150 songs. He was elected a member of the American Academy of Arts and Letters in 1924.

HADOW, SIR WILLIAM HENRY (1859–), British scholar and musician, was born at Ebrington, Glos., Dec. 27 1859. He was educated at Malvern and Worcester College, Oxford, and after taking his degree remained at Oxford as a tutor and fellow of his college. In 1909 he became principal of Armstrong College, Newcastle, retaining this post until 1919, when he became vice-chancellor of Sheffield University. He was in 1918 appointed assistant director of education for the troops by the War Office and also worked for the Y.M.C.A. He was knighted in 1918 and was made a C.B.E. in 1920. In 1922 he became Stevenson Lecturer to the University of Glasgow. Well known as a great authority on the history of music, Sir Henry Hadow also composed many songs and pianoforte pieces besides the incidental music to Robert Bridges' *Demeter* (1905).

He published *Studies in Modern Music* (1894 and 1895); *Sonata Form* (1896); *A Croatian Composer*, a valuable tract on Haydn (1897); the section "The Viennese Period" (1904) in *The Oxford History of Music*, of which he was the editor; *Citizenship* (1923); and *Music* (1924) in the Home University Library.

HAECKEL, ERNST HEINRICH (1834–1919), German biologist (*see* 12.803), died at Jena Aug. 8 1919.

HAFSTEIN, HANNES THÓRDUR (1861–1922), Icelandic statesman and poet, was born Dec. 4 1861. As a young man he became known as a lyrical poet. In 1901 he was elected a member of the Althing, and soon became a leader of the Home Rule party. It was chiefly owing to his influence that Denmark consented, in 1903, to the transfer of the residency of the Minister for Iceland from Copenhagen to Reykjavik. On Jan. 31 1904 Hafstein was appointed to this office and inaugurated a new era of practical reform. His first work was to arrange a telegraphic cable to Great Britain and a net of telegraphs and telephones all over the island. His efforts, however, were hampered by the extremists, who demanded greater political independence from Denmark. Their obduracy led to his resignation in 1908. On the victory of the Home Rulers in 1911, Hafstein again became Minister in 1912, but had to resign in 1914 after new and fruitless efforts to effect reconciliation. He lived, however, to see the full reconciliation between the two countries in 1918, and the recognition of Iceland as an independent state in union with Denmark. He died Dec. 13 1922.

HAGENBECK, CARL (1844–1913), German collector of wild animals (*see* 12.814), died at Hamburg April 14 1913.

HAGGARD, SIR HENRY RIDER (1856–1925), British novelist (*see* 12.816), was knighted in 1912. Among his later novels are *Child of Storm* (1913); *The Ivory Child* (1916); *Love Eternal* (1918); *The Ancient Allan* (1920); and *Heu-Heu: or the Monster* (1924). Much of his time, however, in his later years was devoted to matters affecting the welfare of the Empire. As a member of the Dominions Royal Commission he travelled round the world and, to further schemes for settling ex-service men on the land, he visited various parts of the Empire, writing a
port to the Royal Colonial Institute. He also wrote *Rural D*
mark and its Lessons, 1911. He died in London May 14 19

HAGUE, THE (*see* 12.817), with a population in 1923
328,581, continues to be a centre of diplomatic and internatio
movements. In 1910 the tribunal of arbitration of the No
Atlantic Fisheries met in the city, and in 1915 the Internatio
Congress of Women. In 1917 an agreement was reached h
by British and German representatives as to repatriation
disabled prisoners, etc., and in 1920 a committee of the Leag
of Nations Council met here to frame a scheme for the Perman
Court of International Justice. (*q.v.*) In 1913 the Palace of Pea
to which most countries of the world contributed gifts, was de
cated. In 1922 the house, lent to the town, with his pictures a
furniture, by Dr. Bredius, the art historian, was opened to t
public; in 1924 a museum, chiefly for educational purposes, w
large Greek, Asiatic and Egyptian collections, was established.

HAIG, DOUGLAS HAIG, 1st Earl (1861–), British soldi
was born in Edinburgh June 19 1861, son of John Haig,
Cameronbridge, Fife. He was educated at Clifton and Bra
nose College, Oxford, and in 1885 joined the 7th Hussars.
was promoted captain in 1891, afterwards passed through t
staff college and was employed with the Egyptian Army
1898 during the Nile campaign, for which he was given a bre
majority. On the outbreak of hostilities in South Africa in 18
he went out to Natal on the staff, and was present during t
opening engagements near Ladysmith. He was afterwards ch
staff officer of the cavalry division during Lord Roberts' v
torious advance from Cape Colony through the Orange Fr
State into the Transvaal, and was promoted brevet lieutena
colonel for his services.

In the later phases of the struggle he was in command o
column and later was controlling groups of columns; at the cl
of the war he was appointed A.D.C. to the King, promoted b
vet-colonel, and given the C.B. Col. Haig subsequently co
manded the 17th Lancers for a year, after which he went out
India as inspector-general of cavalry; this appointment he he
until 1906, having been promoted major-general in 1905,
which year he married the Hon. Dorothy Vivian, daughter
the 3rd Lord Vivian. From 1906–9 he was a director in the W
Office, and during this time he was intimately concerned in t
development of the general staff and the improvements effect
in the organisation of the army, which were set on foot wh
Lord Haldane was Secretary of State. In 1907 he published
volume of *Cavalry Studies*. His next appointment was that
chief of the general staff in India, which he held for three yea
being promoted lieutenant-general in 1910. In 1912 he w
brought home to take the command in Aldershot, and in 19
he was made a K.C.B.

On the mobilisation of the Expeditionary Force in 1914, S
Douglas Haig took the field as commander of the I. Army Corp
which he led during the Mons, Marne and Aisne operation
and the first battle of Ypres; he was promoted full general
Nov. for his services. On the division of the British Exped
tionary Force into two armies at the beginning of 1915, he w
placed at the head of the first. On the front of his army duri
1915 there took place the battles of Neuve Chapelle, Festube
and Loos, and at the end of the year he succeeded Sir Joh
French in the chief command. He had been made a G.C.B.
the autumn.

At this time the armies were passing through a period
transition. The regular army with the exception of its cavalr
had almost ceased to exist and the first need was to weld i
remnants, the new armies created by Lord Kitchener and t
Territorial Army, into a whole capable of combined action bo
in attack and in defence. This involved the creation behind t
lines of a large number of schools of instruction in the use of t
new weapons, which the requirements of trench warfare ha
created, and of the old ones which had been brought back wit
the service of war. Beyond and above this technical instructio
came the training of the larger formations of all armies and f
this it was necessary that a certain number of divisions shoul

placed sufficiently far behind the line to allow them the und and the opportunities for gaining experience.

This remained one of the chief items of Sir Douglas Haig's itary policy until a late period of the War. It was a policy ich often brought him into discussion both with the French erals and with the French statesmen, who were continually ssing him to take over a larger extent of front. Sir Douglas ig pointed out that it was not possible to compare a national ny created during the course of the War with one which had n long established in time of peace, and that the Germans oughout the War maintained a greater density of men oppo- the British lines than they did elsewhere. In the event, his icy was justified by the fact that in the latter half of 1918 the itish Army, was as a whole, at least as efficient as any which s then fighting in the War.

The campaigns and battles of the British Army in France and lgium are dealt with elsewhere and it is here only necessary to er to the principles which guided Sir Douglas Haig in certain the crises of the War. The first of these during his command se out of the German attack on Verdun during the first half 1916. On that occasion he assisted the French by relieving ir troops in the front and by preparing for the battle of the mme. While that battle disclosed defects both of preparation d of execution, its results convinced Sir Douglas Haig that it d caused such exhaustion of the German armies as should be ploited at the earliest possible moment. He therefore agreed th Joffre to renew the battle early in 1917.

But the battle of the Somme had caused grievous losses and e gains of ground as shown on the maps appeared trifling. erefore, neither French nor British statesmen were prepared agree to a policy which to their minds seemed likely to exhaust eir resources before it caused the enemy to yield. The con- uence of this was the replacement of Joffre by Nivelle and e assembly of an Allied Conference at Calais at the end of b. 1917, at which it was decided to give Nivelle the general ection of the British Army, while he was at the same time to in active command of the French Army. This arrangement, litarily unsound, early produced friction. For Nivelle, who s ill-informed of events on the British front, issued to Haig structions which were inappropriate both as to form and sub- nce. These differences were adjusted at a further conference London, but they created the impression that Haig was posed to any form of unity of command, which was not true.

The direct result of the failure of Nivelle's campaign was a ve of depression which spread through the French Armies d resulted in serious mutinies. Pétain, who had succeeded velle, appealed to Haig to keep the Germans occupied while was restoring the morale of the French troops. To this peal Haig responded by opening in the summer of 1917 a mpaign in Flanders, which began with Plumer's victory at essines and was followed by the battle of Passchendaele. It s only with difficulty that Haig won the consent of the British vt. to this campaign. By the middle of Oct. of that year tain was able to tell Haig that the French Army was suffi- ntly restored to be able to look after itself; and it might have en wiser to have stopped the battle of Passchendaele then, as no equate return was gained for the exhaustion caused by the olongation of the attack in execrable weather.

The crisis brought about by the success of the German-Aus- an attack on the Italians at Caporetto following on the col- se of Russia, resulted in the creation in Nov. 1917 of the preme War Council, the first meeting of which was held at e end of the following January. This meeting had been preceded a renewal of French demands for an extension of the British nt, which Haig eventually met by agreeing to take over a rtion of the line at and south of Peronne with his V. Army. this meeting a difference of policy between Haig and his vt. was disclosed. The commander-in-chief anticipated an rly attack by the Germans and asked for reinforcements: e Prime Minister wished for an offensive campaign in Pales- e, and won his way; and at this same conference, it was cided to create an Allied general reserve on the Western Front under the control of the military representatives of the Supreme War Council with Foch as chairman. During Feb. 1918 Haig became more than ever convinced that a great German attack on his front was imminent, in which he differed from the military representatives, who did not expect it before May. When the military representatives applied to him for divisions for the general reserve, he answered that in view of the lack of reinforcements, the extension of his front and the massing of German troops, he would be unable to furnish these divisions, and the formation of the general reserve broke down.

With what calm determination Haig met the great German offensive of the spring of 1918 is described elsewhere. In the most critical days of that offensive it was Haig's direct intervention with the British Govt. which brought Lord Milner to France, a visit which resulted eventually in giving Foch direct control of the Allied Armies. With Foch Haig's relations were as harmonious as they had been with Joffre, and in the late summer of 1918 the British commander-in-chief reaped at last the reward of his patient policy. When in Aug. 1918 Rawlinson's IV. Army won the victory of Amiens, Foch desired that Rawlinson should follow up his success. Haig, convinced that this would result in another deadlock, and confident now in the superior morale and efficiency of his army, persuaded Foch to agree to an extension of the battle northwards, and so came about the breaking of the Hindenburg line which made it clear that victory could be won in 1918.

For his great services Sir Douglas Haig was raised to the peerage as Earl Haig and Baron Haig of Bemersyde and was given a grant of £100,000. The Order of Merit was also conferred upon him, and the ancestral home of the Haigs at Bemersyde was purchased by national subscription and presented to him. On returning home he was for a short time commander-in-chief in Great Britain, but when that position was abolished he refused other offers of employment and devoted himself wholly to the welfare of ex-service men. He succeeded in uniting other organisations with the British Legion, of which he became president. He also created and became president of the British Empire Services League, a union of the ex-service men's organisations of Great Britain and the Dominions; he was also appointed chairman of the United Services Fund, which together with the fund he established for the benefit of ex-service men forms one of the largest benevolent organisation in the country. (*See* LOOS; NEUVE CHAPELLE; SOMME and articles on other battles of the World War; also WESTERN FRONT.) See *Sir Douglas Haig's Despatches*, ed. J. H. Boraston (1920) (F. B. M.)

HAINISCH, MICHAEL (1858–), Austrian statesman, was born Aug. 15 1858, at Aue, near Gloggnitz, Lower Austria, the son of a manufacturer, and Marianne Hainisch, a pioneer of women's rights. After a short career in the Austrian public service, he devoted himself to the study of social and agricultural questions. He was founder with Engelbert Pernerstorfer of the Gesellschaft der Fabier on the model of the British Fabian Society. Hainisch, who was particularly active in the cause of popular education, founded and endowed many hundreds of popular libraries. His works include: *Die Zukunft der deutschen Oesterreicher* (1892); *Voraussetzungen und Berechtigung des Sozialismus* (1919); *Die Landflucht* (Jena, 1923). Hainisch was elected first President of the Austrian Republic in Dec. 1920 and re-elected unanimously for a further period of four years, Dec. 1924.

HAITI (*see* 12.824), a republic in the West Indies and a member of the League of Nations. Its area is 10,204 square miles. No reliable census of the population has been taken. Estimates vary from 1,500,000 to 2,500,000, the most reliable giving 2,028,000 in 1924.

I. POLITICAL HISTORY

The principal event in Haitian affairs in the period 1910–25 was the military intervention on the part of the United States, which developed into a close political and fiscal protectorate. The first part of the period was marked by constant revolutionary turmoil and by rapid political disintegration. In July 1911

President Simon was overthrown and on Aug. 14 1911 Cincinnatus Leconte became president. A year later (Aug. 8 1912) the presidential palace was blown up and Leconte and a number of his followers killed. The National Assembly at once elected Tancrede Auguste, a prominent planter; he died the year after, and on May 4 1913, Senator Michel Oreste was elected.

Intervention of the United States.—Dec. 1913 ushered in a period of political turbulence, and three military presidents assumed office in quick succession: Oreste Zamor, on Feb. 8 1914; Davilmar Theodore, on Nov. 7 1914; and Vilbrun Guillaume Sam, on March 4 1915. The last named, after withstanding the attacks of his opponents for several months, was compelled to seek refuge in the French legation in the night of July 26 1915, while 200 political prisoners in the gaol of Port-au-Prince were massacred by order of one of his followers. At the funeral of the victims a party of mourners invaded the French legation, dragged out the ex-president, handing him over to the mob for death, and killed the ex-gaoler. Two hours later a U.S. cruiser arrived at Port-au-Prince and landed marines. U.S. forces occupied the country, disarmed the natives and restored order. Although U.S. naval officers assumed charge of most administrative functions, the Haitian governmental organisation remained intact. On Aug. 12 1915 Sudre Dartiguenave was chosen by the Haitian Congress as president. A treaty having been accepted by the Haitian Govt. in 1916, the U.S. Senate advised ratification. Ratifications were exchanged at Washington and the treaty was proclaimed on May 3 1916.

Modelled upon the American-Domingo Convention of 1907 (*see* 24.194), this instrument was designed to secure political stability and economic development in Haitian affairs by a political and fiscal protectorate, to remain in force for a period of 20 years. By its terms the President of Haiti appointed, on the nomination of the President of the United States:—

(*a*) a receiver-general of customs to take charge of the customs houses;

(*b*) a financial adviser to be attached to the Ministry of Finance;

(*c*) American officers to organise and command a Haitian constabulary (gendarmerie) which was to replace the Haitian armed forces, such officers to be later succeeded by qualified Haitians;

(*d*) engineers and doctors to supervise the public works department and public health services respectively.

Haiti agreed not to increase the public debt and not to modify the customs duties without the consent of the United States; the United States undertook to intervene when necessary for the preservation of Haitian independence and the maintenance of a stable and effective government. The treaty provisions were promptly put into effect, and determined entirely the subsequent course of events.

In the early period of American intervention the division of authority caused friction, but with the appointment in 1922 by the President of a high commissioner to supervise and co-ordinate the activities of the treaty officials and the military occupation, native irritation and the friction between the American authorities and the Haitian Govt. disappeared. The U.S. marines were later withdrawn from all interior points and concentrated at Port-au-Prince and Cape Haitien. The maintenance of order was placed in the hands of the Haitian gendarmerie. This was composed of native troops, but the officers generally were officers and enlisted men of the U.S. Marine Corps.

The future of Haiti presented in 1921 the gravest problem of United States influence in the Caribbean (*q.v.*). Early termination of military occupation was, in the opinion of those in responsible charge, certain to result in reversion to old conditions. On the other hand, public sentiment in the United States did not view with satisfaction the definitive abandonment of the one great opportunity left the negro race to demonstrate, even after repeated trial, an ultimate capacity for self-government. Until 1921 the establishment of civil order had engaged the best energies of the American officials. With this accomplished, opportunity was afforded for rendering the further offices contemplated by the treaty in a way conducive to the ultimate assumption of civil authority by the Haitian Govt.; subject only to those reservations as to political stability and fiscal solvency in force in other areas within the range of American influence in the Caribbean.

Borno as President.—Louis Borno, who was elected on April 10, was inaugurated on May 15 1922 as president of the republic. He found civil order firmly established through an efficient native gendarmerie. Roads had been constructed and bandi eliminated, and the peasantry enjoyed, for the first time p haps in their country's history, complete freedom. Pu health services had been greatly improved under American sup vision, great progress being made in town sanitation. A vigor policy of financial reform was adopted, with very satisfact results. The public debt, which in 1915 amounted to $36,000,c had been reduced to $22,046,252 at the close of the fiscal y 1924–25. The budget had been balanced and a comforta surplus realised by 1923–4, thus enabling the Govt. to sp substantial sums on public works and other developme Borno was re-elected president in 1926.

II. ECONOMIC HISTORY

Production and Trade.—The chief crop is coffee, which represen in 1925 some 75% of the total income of the country. Other im tant products are cotton and sugar. Great efforts are being mad develop systematic cultivation, for even in 1925 coffee and cot grew semi-wild. An agricultural school had been established at Po au-Prince, experimental stations set up under American official system of premiums inaugurated to encourage coffee growers, a attempts made to improve the coffee and sugar crop and encour the growth of other crops, such as cocoa, sisal, hemp and tobac A modern sugar-cane mill and refinery were erected at Port- Prince, as well as a smaller plant near Cape Haitien, and also cot ginning plants, etc. Means of communication and transport being improved in order to open up the country and develop agricultural, forest and mineral resources; in 1925 some 7,500 m road were open to traffic, motor roads totalling about 650 m. lin up the chief towns. Only some 60 m. of railway line were in opera in 1925, but the lines were being extended. Banking is in the ha of the National Bank of Haiti, a subsidiary of the National C Bank of New York, and the Royal Bank of Canada.

Foreign trade had greatly improved between 1915 and 19 The following table shows the value of imports and exports fr 1916 to 1924:—

	Imports $	Exports $
1916–7	8,606,086	8,932,88
1917–8	10,180,693	7,743,53
1918–9	17,117,608	24,762,22
1919–20	27,398,411	21,620,92
1920–1	11,957,206	6,590,40
1921–2	12,350,271	10,712,21
1922–3	14,157,963	14,591,01
1923–4	14,696,128	14,176,33
1924–5	20,237,565	19,403,76

The chief articles of export in 1923–4 were coffee, valued $10,361,776; raw cotton, $2,068,628; raw sugar, $620,412; logw and logwood extract, $440,670; cotton seed, $202,580; and coc $139,341. Exports to France were valued at $9,369,923; the Un States, $1,329,251; Denmark, $847,118; the United Kingd $722,699; Germany, $652,688; and Belgium, $509,375. Impo were mainly from the United States, $11,817,376; the Uni Kingdom, $984,600; France, $885,228; and Germany, $447, Both imports and exports increased during 1924–5, when the to trade approximated $40,000,000, with a small balance in favour Haiti.

HALDANE, RICHARD BURDON HALDANE, 1st Viscou (1856–), British statesman, philosopher and lawyer (12.831). In 1910 he was appointed chairman of the royal co mission on university education in London. To organise a u versity of the first order in, of, and for London, which sho secure for science and scholarship, under wise conditions, t full use of the great resources, human and material, of the cap of the British Empire, was a task demanding constructive stat manship in a high degree. The report of this commission (C 6717) dated Dec. 1911 dealt faithfully and vigorously with t problems placed before it. Effect has not yet been given to mmendations. Time may show that the university will and reform itself from within. If, and when, the university sets f, or is set, in order, the counsels of this commission, which the impress of the chairman's mind, will form the basis of ew activities.

March 1911 he was raised to the peerage and appointed a ıber of the Judicial Committee of the Privy Council—that t important tribunal which constitutional lawyers know to practical bond of Empire. As a student of the principles ch underlie all systems of law, he found the cases brought re the committee to be of absorbing interest, perhaps, most cially, those from India, where the fundamental principles ındu law are based on religious duty and philosophic con- s, unfamiliar to the west.

1912, at the request of the Cabinet, he visited Berlin to uss disarmament proposals and on his return reported to the inet information he gathered there as to the attitudes and litions of those then guiding the policy of Germany. To be a senger of conciliation and co-operation between the two ons was a duty for which he was in every sense especially ipped, but he was, and soon knew he was, to be baulked by conditions under which Germany was then ruled. Much ty capital was made out of this visit, both then and later ing the War. To have refused the opportunity was impos- e. To have sent any other member of the Cabinet, would e been infructuous. Something resulted from the mission, not all that he had hoped for. Lord Haldane accepted the arting of the full result he had looked for with characteristic rage and dignified silence. In 1912 he succeeded Lord Lore- n as Lord Chancellor and presided over the House of Lords h dignity and efficiency.

Vhen the War broke out in 1914, the great reorganisation of War Office which he had effected was tested to the extreme. labours were justified by their fruit. A new model had n created. There was a new spirit in the army. It had been on the way of becoming a learned and scientific profession. had been organised in accord with sound principles and its stituent elements had been brought into close relationship l enabled to co-operate with and understand one another. By creation of the Officers' Training Corps in 1909, the universi- and schools were able to contribute in the time of need ctly the type of officer required. The Militia had been laced by a Special Reserve of real value as events showed. Territorial Army had been created, and saved the situation re than once. The General Staff was brought into existence the issue of a special army order, establishing it on the foot- it held during the War and after. To Lord Haldane, again, lue the decision of the Dominion Conference in 1907, accept- the principle of an Imperial General Staff, by which con- ted action and intelligent co-operation between armies drawn m all parts of the Empire was made possible. The experi- ntal mating of Minerva with Mars had, indeed, been fruitful l felicitous.

Practical reasons and popular prejudice account for his sence from the first Coalition Ministry in 1915, when he eived the Order of Merit. He was then free—as free as any riot of his nature and temperament could be in such stressful s—to turn to philosophy. He published in 1921 *The Reign Relativity*, a masterly presentment of profound, scientific and taphysical thought, and in 1922, *The Philosophy of Human-*, an abiding memorial of the dictum *Das Geistige allein ist Wirkliche*. When Einstein came to England to lecture, he s the guest of Lord Haldane, who presided over the gathering ich heard the exposition of the theory of relativity from its coverer. Always eager to promote national education, Lord ldane devoted much time and energy to the Workers' Educa- nal Association, which owes much of its success to his support.

Lord Haldane was Lord Chancellor in the Labour Ministry of Ramsay MacDonald (1924), and working chairman of the mmittee of Imperial Defence, where his experience, tact and lefatigable industry were invaluable, and, on the fall of the bour Ministry, Mr. Baldwin invited him to continue his long association with it. The report of the Machinery of Government Committee (Cd. 9230, 1918), of which Lord Haldane was chairman, pointed out that "Further provision is needed in the sphere of civil government for the continuous organisation of knowledge and the prosecution of research in order to furnish a proper basis of policy." Accepting this declaration of principle, Mr. Baldwin established in 1925 the Committee of Civil Research, on which Lord Haldane has served as a member. Thus, through every department of State, in education, in university life, in the army, in the law and in industry are found the effects of his master mind, of his clear vision, of his resolute adherence to first principles and of his practical philosophy. Elected first Chancellor of Bristol University, he has been Lord Rector of Edinburgh, and has received many honorary degrees. His book, *Before the War*, gives an account of his political activities at that time.

HALE, GEORGE ELLERY (1868–), American astronomer, was born at Chicago, Ill., June 29 1868. He studied at the Harvard College Observatory and the Massachusetts Institute of Technology, graduating in 1890. He was director of the Kenwood Astrophysical Observatory, in Chicago, from 1890 to 1896. From 1892 to 1905 he was at the University of Chicago as associate professor of astrophysics, professor, from 1897, and director of the Yerkes Observatory, after 1895. In 1904 he became director of the Mount Wilson Solar Observatory (Cal.) of the Carnegie Institution of Washington, a position which he held till 1923, when he became honorary director in charge of policy and development. He invented the spectroheliograph first used in 1892 for photographing solar prominences, and won an international reputation for his solar and stellar spectroscopic work. He was awarded the Janssen Medal by the Paris Academy of Sciences in 1894, the Rumford Medal by the American Academy in 1902, the Draper Medal in 1903, a gold medal by the Royal Astronomical Society in 1904, the Bruce Medal by the Astronomical Society of the Pacific in 1916, and the Janssen Medal by the Astronomical Society of France in 1917. He was the author of *The Study of Stellar Evolution* (1908) and *Ten Years' Work of a Mountain Observatory* (1915), besides numerous papers in scientific publications.

HALIFAX, Nova Scotia (*see* 12.843).—The population of the city in 1921 was 58,372. The public buildings and many of the houses built of stone show a considerable taste in architecture. Much of this stone was brought from the dismantled homes and fortifications of Louisburg. About one-tenth of the city area was devastated by the explosion on Dec. 6 1917, of a French steamer carrying 3,000 tons of T.N.T., on colliding with a Norwegian steamer on its way with a relief cargo for Belgium. The reconstruction of a Greater Halifax has been carried out on modern lines of town planning.

The harbour is accessible all the year round to the largest vessels. New docks and railway stations, in course of construction, will give it an area of over 200 ac. and make it one of the best equipped ports in the world. Grain elevators and conveyor systems will meet the needs of expanding commerce. Halifax claims to have the lowest port charges on the Atlantic coast. There are a number of manufacturing industries, including the largest sugar refinery in Canada, and the city is also an important distributing centre. Halifax is the chief winter port of Canada and the Atlantic terminus of the Canadian National Railways. It has a naval dockyard and training school.

HALL, GRANVILLE STANLEY (1846–1924), American psychologist and educationalist, was born at Ashfield, Mass., Feb. 1 1846. He graduated from Williams College in 1867 and took the degree of Ph.D. at Harvard in 1878. After holding the chair in psychology at Antioch College, 1872–6, he pursued further studies at Berlin, Bonn, Heidelberg and Leipzig. He was professor of psychology in Johns Hopkins University, 1881–8, and was then elected the first president and made professor of psychology of the newly formed Clark University, Worcester, Mass. which, under Hall's personal leadership, was devoted, during its first two decades, chiefly to educational research. He became widely known as an exponent of the culture-epoch theory of mental development, a doctrine set forth in his most influential work, *Adolescence*, 2 vol. (1904). During the later years of his presidency his influence perceptibly diminished, this being partly due to the lack of scientific method in his work. He resigned in 1920 and died April 24 1924.

Hall's numerous published works include: *Educational Problems* (2 vol., 1911), *Founders of Modern Psychology* (1912), *Senescence* (1922), and *Life and Confessions of a Psychologist* (1923).

HALLE, WILMA MARIA FRANCISCA, LADY (1839–1911), Anglo-German musician (*see* 12.853), died in Berlin April 15 1911.

HALSBURY, HARDINGE STANLEY GIFFARD, 1st Earl of (1823–1921), British lawyer and politician (*see* 12.867), died in London Dec. 11 1921. The year of his birth, earlier given as 1825, was subsequently found to have been wrongly stated. The records of Merton College, Oxford, show him to have been born on Sept. 3 1823.

HAMBURG, Germany (*see* 12.871), with a population in 1922 of 1,025,502, is the second city of Germany. Its commerce, industry and shipping had been increasing up to the outbreak of the World War, which sharply arrested its development, but after the Armistice it began to recover. In 1923 the port was entered by 13,192 seagoing vessels of 15,344,999 tons, as compared with 16,427 of 14,185,496 tons in 1913. Traffic at the end of 1925 was about 90% of the pre-War figure. The proportion of shipping flying the German flag was only half what it had been, and emigrant and tourist traffic much less. The Hamburg-Amerika line, which had made great strides before the War, had 89 steamers of 386,000 tons in 1924. Since 1910 new docks have been built on Waltershof Is., forming a second free port, and large shipyards were laid down at Finkenwerder in 1918. New buildings include the Trade Corporation House (1912–6) in Neustadt, the Museum of Hamburg Antiquities (1914–20) and two ten-storyed office buildings of vitreous brick on the Messberg. The Exchange was rebuilt in 1908–12, and the Institute for Tropical Diseases in 1914. Great S. Michael's Church, burnt down in 1906, has been re-erected on the old lines and the Kunsthalle, to the east of the Binnen-Alster, has been much enlarged. The tunnel under the Elbe from the St. Pauli district to Steinwärder, which is entered by lifts, was finished in 1911; but a two-storyed bridge over the river, begun in 1914, was still unfinished in 1925.

The university, founded in 1918, with a democratic constitution, is in Rotherbaum, to the north of the city, in a building originally designed as a lecture hall. Near it is a statue of Hermann von Wissman, the explorer, which was erected at Dar-es-Salaam and removed here in 1922. Space in Ohlsdorf cemetery for 700 graves of men who died in the district during the World War has been acquired by the British Government. A memorial commemorating the seamen of Hamburg who died as prisoners of war in America was unveiled in 1920.

In 1917 a commission was appointed to bring about a reform of the class franchise which had hitherto existed in the Hanseatic cities, and a measure of electoral reform was adopted. The city and territory had nevertheless as severe an experience of the revolutionary movement as any region of Germany. The Council of Workmen and Soldiers assumed complete political power in Nov. 1918. The region of Cuxhaven belonging to Hamburg declared its independence in Jan. 1919 under Communist leadership, but the republic only lasted four days. In Jan. and Feb. 1919 Communist disturbances broke out in the city itself. The new constitution adopted in 1920, reduced the authority of the senate, and the power which it formerly wielded is now in the hands of the Bürgerschaft (representative assembly), which consists of 160 members elected on the system of proportional representation.

HAMBURG, UNIVERSITY OF.—By a process of natural development the University of Hamburg was formed in 1919 from the material of the Colonial Institute, and consists of the faculties of law, medicine, philosophy and natural science. Special facilities exist for study of the history and culture of the Orient generally, of India, China, Japan, Africa and the South Seas. Anthropology, folklore and missionary problems among the many notable features of the courses—especially summer course, which attracts a large number of students.

HAMILTON, SIR IAN STANDISH MONTEITH (1853– British soldier, was born at Corfu Jan. 16 1853. Educate Wellington College and in Germany, he joined the arm 1872. He served with the 92nd Highlanders in the Afghan and the Boer War of 1881, and was severely wounded on Ma Hill, one arm being permanently disabled. He was then several years intermittently on the staff of Sir F. (Lord) Rob He served in the Nile Expedition of 1884–5, in Burma in 188 and on the staff of the Chitral Relief Force in 1895. He c manded a brigade on the North-West Frontier in 1897, and a wards the School of Musketry, Hythe. In the South Afr War he commanded a mounted infantry division during advance from Bloemfontein to Pretoria and into the eas Transvaal. He returned home early in 1901 to become mili secretary at the War Office, but towards the end of the went back to South Africa nominally as chief of the staf Lord Kitchener, although in reality he was employed chief the commander-in-chief's deputy to control particular gr of operations from time to time during the closing stages of struggle.

He was afterwards again military secretary and then qua master-general at the War Office, and in 1904 he went out to Far East to accompany the Japanese armies in the field. impressions under the title *A Staff Officer's Scrap Book* (2 1906–7), by reason of the interest of its subject, the charm the author's style, and the combination of war experience an imagination which inspired his judgments and criticisms, at took rank in Europe as a modern military classic. His lite ability, though a token of unusual imagination and clearnes thought, rather prejudiced him throughout his career in the of old-fashioned soldiers. On his return he had charge of Southern Command until 1909, and was afterwards adjut general at the War Office for a year. He took a prominent on behalf of the voluntary service system during the camp in favour of compulsory service led by Lord Roberts, and in course of this controversy he published a book *Compul* *Service* (1910), which he wrote at the request of Lord Hald In 1910 he was appointed commander-in-chief in the M terranean and inspector-general of the Overseas Forces.

On the outbreak of the World War in 1914 Hamilton se for some months as commander-in-chief of the Home Def Army in England. Then in March 1915, he was selected to charge of the Mediterranean Expeditionary Force (*see* D danelles Campaign). The naval effort to force the Dardan having failed, he found himself obliged to undertake operat in the Gallipoli Peninsula, and although his army was very equipped for the task, he succeeded in landing it in the face of enemy, but was brought to a standstill. Having, after consi able delay, received substantial reinforcements, he made a g effort in Aug. to improve his position, but partly through inertia of some of the local commanders, sent out without sulting him, the operations miscarried, and a situation of st mate arose. The Government consulted him in Oct. as to expediency and feasibility of withdrawing from the penins and on his pronouncing himself strongly opposed to suc policy he was replaced by Sir C. Monro and returned ho In 1920, after the issue of the *Report* of the Dardanelles C mission, he published his own story of the campaign under the title of *Gallipoli Diary* (2 vol., 1920), and in 1921 *The S* *and Body of an Army*. For this *Encyclopædia* Sir Ian wrot brilliant article on War. (B. H. L. H.

HAMILTON, Ontario (*see* 12.891), had in 1921 a populatio 114,351. It was estimated (1924) at 120,235. Hamilton's graphical position gives it excellent shipping facilities on Great Lakes. The city is on the Canadian Pacific and Cana National Railways and is connected with several lines of United States. It is the centre of a system of city and subur lines, and the municipal supply of electric power is cheap and p tically unlimited. Hamilton has about 700 factories, inclu largest plough works and implement works in the British pire. Besides its Anglican and Roman Catholic cathedrals, city has 89 churches, 50 banks, 45 schools (public, private technical), five hospitals and three public libraries.

AMMARSKJÖLD, HJALMAR (1862–), Swedish states- , was born at Tuna Feb. 4 1862 and educated at the Uni- ity of Upsala, where in 1891 he was appointed professor ivil law. After establishing his reputation as a jurist, he ed an important part in national politics and became Min- of Justice in the Van Otter Cabinet, holding this post from –2 when he was appointed president of the Göta high court. 905 he was Minister of Education in the Lundeburg Cabinet also a delegate to the conference with Norway at Karlstad e time of the dissolution of the union. He was Swedish Min- in Copenhagen from 1905–7 when he became governor dshörding) of the province (län) of Upsala. He had been dish delegate at the Hague conferences in regard to private rnational law in 1900 and 1904, and from 1904 was Swedish nber of the Hague International Board of Arbitration. In he was Sweden's leading delegate to the Hague Peace Con- nce and in 1909 acted as president of the Franco-German rd of arbitration in regard to the Casablanca affair. He pre- d in 1913 over the Franco-Italian arbitration court regarding seizure of vessels during the Tripoli War. In Feb. 1914 he eeded Staaff as Prime Minister, retaining this post during World War until 1917 (*see* SWEDEN). Hammarskjöld became ember of the Institut de Droit International and a curator he Académie de Droit International at The Hague. In Dec. he was appointed by the Council of the League of Nations rman of the commission relating to the codification of inter- onal law.

AMMERSTEIN, OSCAR (1847–1919), American musical ctor, was born in Berlin. He went to the United States in 3, where he made money as an inventor of cigar manufac- ng machinery. In 1870 he became lessee and manager of a ery theatre and after 1880 built and operated the Harlem ra House, the Olympic, the Victoria and other theatres. In 5 he built the Manhattan Opera House, in avowed rivalry the Metropolitan Opera House. In the operas which he luced there he broke away from the classics and presented works of modern composers, for example Massenet's *Thäis*, ussy's *Pelléas et Mélisande* and Charpentier's *Louise*. He red artists such as Melba, Tetrazzini, Bonci and Renaud Campanini as conductor and artistic director. In 1911, ever, he was compelled to sell his concern to the Metropol- Opera Company, agreeing to abstain from producing grand ra for 10 years within the latter's territory. He then went ondon and built the London Opera House, but here again he d to make a commercial success of the undertaking. Re- ning to New York in 1912 he built another theatre for the pose of entering his former field of grand opera, but the Met- olitan Opera Company secured an injunction prohibiting from so doing. He opened his new house under the name of Lexington Theatre in 1914, with the usual form of theatrical gramme. He died in New York City Aug. 1 1919.

AMMOND, JOHN HAYS (1855–), American mining en- eer, was born in San Francisco March 31 1855. He studied at Sheffield Scientific School, Yale University (Ph.B., 1876), af- vards taking a course at the Royal School of Mines, Freiburg, ony. In 1880 he was engaged in the U.S. Geological Survey he California gold fields, afterwards practising as consulting ineer, in which capacity he visited most of the countries of th and South America. In 1893 he became associated with nato Bros. and Cecil Rhodes in South Africa, acting as con- ng engineer for the Consolidated Gold Fields Co. of South ca, the British South Africa Co., and the Randfontein Estates d Mining Company. As one of the leaders of the Rand faction, vas, in Jan. 1896, after the Jameson Raid, arrested and con- ned to death, but the sentence was commuted, and later he released on payment of a $125,000 fine. In 1900 he returned he United States and became largely interested in mining erties and irrigation projects both in the United States and Mexico. He was president of the Panama Pacific Exposition Commission to Europe, 1912; chairman of the World Court Commission, 1914–5; and chairman of the U.S. Coal Commission 1922–3. He became general manager and consulting engineer of the Guggenheim Exploration Company.

His son, JOHN HAYS HAMMOND, JR. (1888–), American inventor, was born in San Francisco April 13 1888. He studied at the Sheffield Scientific School, Yale University (B.S., 1910). Devoting himself to electrical developments and experiment, he invented a torpedo for coast defence controlled by wireless energy, a system of radio control of ships and a system of selective radio telegraphy; also various electrical devices the use of which for military purposes was secured by the U.S. Government.

HAMSUN, KNUT (1859–), Norwegian author, was born Aug. 4 1859 at Lom in the Gudbrandsdal Valley, the son of poor parents. He started to write at the age of 19 when he was a shoemaker's apprentice at Bodö in North Norway, and for the next 10 years earned his livelihood in various ways such as coal trimmer and country schoolmaster. He eventually went to America, where he became a tram conductor in Chicago and a farm labourer on the prairies. In 1888 he published, in a Danish magazine, the fragment of a novel, *Sult*, which was later translated into English, as *Hunger*. This work at once attracted attention by the beauty of style and originality of treatment. His works from this time onward revealed a richness of talent which rapidly increased his reputation. He is akin to the Russians in his psychological analysis of morbid types, but the American influence is apparent in his use of startling metaphors and the aptness of his expressions. An intense love of nature also characterises his work. He is chiefly known to the English-speaking world by his three novels, *Hunger*, *Growth of the Soil* and *The Woman at the Well*. In 1920 Hamsun was awarded the Nobel Prize for literature.

HANDICRAFTS, ARTISTIC (*see* ARTS AND CRAFTS, 2.700).—The revival of interest in and the practice of the artistic handicrafts which was organised in the early 'eighties in England by Morris, Crane, W. A. S. Benson, W. R. Lethaby and their associates exercised an influence which soon extended to other European countries, the United States and Canada. Although it must be admitted that the dream of its founders has not been and cannot be realised, that influence is not dead. The quality of production may and must vary from time to time with the varying skill of the worker; but a standard of excellence has now been promulgated which is—if not yet equal to the hopes of the pioneers of the movement—at least well advanced in that direction.

The arts and crafts movement was, and is, a protest against machine-made goods and commercialism, and though these, in the nature of things, must continue, definite results have been achieved. The influence of the movement upon the trade side of art-industry has been undeniable. The machine-made article cannot—or, at all events, does not yet—equal in technical execution the hand-made article. But in colour, in pattern, in form, one has only to compare the shop-window display of the period since 1910 with that of the earlier period, to see how great has been the advance of taste. And there has never been so great a demand for books, magazines and the written word generally relating to the arts, as there is at present; in itself a fairly convincing evidence of the growth of interest in the subject on the part of the public.

I. HANDICRAFTS IN GREAT BRITAIN

An effort is being made, in Great Britain, by various societies and with some support from the Govt., in the direction of a general revival of village handicrafts. It is too soon to measure its success; but the movement is worthy of record.

Furniture.—While it is true that the most important of the industrial arts, the making of furniture, is suffering to some extent from a fashion for 18th-century reproductions, steady progress is being made towards what may turn out to be a veritable 20th-century style, of which the distinctive features appear to be simple construction based on good joinery rather than on cabinet-making. The use of woods selected for their natural beauty and undefiled with polish or stain is another characteristic. Ornament is scantily applied and with increasing attention to utility and comfort; and the general tendency is towards rather substantial and even massive forms, although work on more delicate lines is not wanting. Undoubtedly the most distinguished figure in these, and in other, branches of craftsmanship was Ernest Gimson, whose style seems to be well on its way to becoming a tradition. But distinguished work in England has also been done by E. A. and S. H. Barnsley, P. Waals, A. Romney Green, S. Gordon Russell, C. A. Richter and Ambrose Heal. The wood carving of G. Jack and Lawrence Turner and the carved wood puppets and other figures by William Simmonds are especially notable. Continental furniture follows much the same principles, with perhaps more reliance on mass than on line; as for instance in the work of Louis Sognot of Paris, Hans Hloucat of Vienna and the productions of the Deutsche Werkstätten, Munich.

Silversmiths' Work.—In silversmiths' work, progress has hardly been maintained so far as regards a demand on the part of the public for really fine personal craftsmanship, although, again, the design characteristic of the revival is being reflected to some extent in commercial products. Most of those who are concerned with presentation plate still seem afraid to entrust their commissions to artists whose names and individuality would enhance values. For church purposes, however, admirable work has been done, especially as altar furniture, pastoral staves, etc., by Alwyn Carr, Henry Wilson, Omar Ramsden, Edward Spencer and others; and the series of episcopal and other seals engraved by Cecil Thomas would come into this category. A search for variety has revived, in new form, a combination of shagreen with silver or copper, worked with considerable success by Paul Cooper. Modern jewellery, with its distinctive use of stones *en cabochon* rather than cut, has perhaps kept its small place, but has not affected the more popular taste to any appreciable extent, and of enamels it can only be said that the art has lost rather than gained ground. The silversmiths' work of the Scandinavian group shows promise and originality, and French artists still display extraordinary technical skill and ingenuity; but for obvious reasons there is little new movement to record.

Textiles.—Textile fabrics generally show a tendency towards simple and effective colouring, side by side with a revival of the brocade and chintz patterns of the 18th century, and a still powerful oriental influence. Patterns directly based on flower and plant form have no longer the vogue of the earlier years of the century; though the renaissance of good needlework, due very largely to the efforts of Miss May Morris and Mrs. A. H. Christie, as well as to the effective work done by the Dept. of Textiles of the Victoria and Albert Museum under Mr. A. F. Kendrick, seems to be firmly established in Great Britain. On the Continent, peasant design has influenced pattern, and a definite revival of tapestry in Sweden is to be noted. In this class reference must be made to the effect of the costume designs of Léon Bakst originating a new movement which has spread far beyond its original purpose. Design in carpets and rugs, so far as it exists at all, appears to be almost entirely subservient to Persian and Near Eastern motives; apart from these, however, public taste seems to prefer unpatterned colours to an increasing extent.

Glass.—Much more attention has recently been given to original design in glass-ware on the continent of Europe than in Great Britain; and while there is perhaps too strained an effort in this direction, it cannot be denied that a fair amount of good work is being done. That of Marinot of Paris is decidedly in this class, for it keeps well within reasonable limits in appropriate treatment of the material and yet achieves a novel and highly decorative effect. Some excellent glass for table use is being made in Sweden and Denmark; and the more highly elaborated designs of E. J. Margold of Darmstadt and of the cut-class made under the direction of Prof. G. Beckert of Czechoslovakia are enterprising in pattern and by no means without interest. If in this
department Great Britain is behind, in stained glass she
made distinct progress. A Gothic tradition is, in this insta
almost essential; but its treatment of subject can be, an
sufficiently modern for all practical purposes. The desig
Christopher Whall, P. Woodroffe, G. Kruger Gray, G. P
and others have continued and developed the new life inst
in this art by William Morris and Sir P. Burne-Jones.

(E. F.

II. HANDICRAFTS IN THE UNITED STATES

In the first quarter of the 20th century the artistic h
crafts, or arts and crafts, have made substantial progress i
United States of America. When the revival began with
Boston Exhibition in 1897, the standards were not partic
high and the amount of work being done throughout the cou
was insignificant. The Boston Society of Arts and Crafts
organised in this year and has maintained its leadership i
movement ever since. Its annual sales have increased
$4,000 in 1901 to over $200,000 in 1925.

The arts and crafts were taken up with fervour and a
number of societies were soon organised. The result was
with the showing at the St. Louis Exposition in 1904 and a
Boston Exhibition in 1907, fairly good standards were establi
in all branches of craft work. It must be admitted that crafts
who were foreign-born and trained contributed largely to
rapid advance. While some of the initial enthusiasm died d
after a few years, there has been a decided renewal of int
since the World War. Distinguished work is now being d
which has had considerable influence on commercial work
in the improvement of popular taste.

Probably the most important advance has been made in
field of stained glass, in which it may be said that an outstan
American style has been established, notable for its decora
character and its emotional quality of colour. While it
definitely carries on the traditions of the early stained glas
is already adding traditions of its own. The fact that the
portation of fine stained glass from Europe has dropped off at
75% in the last ten years, although there has been an unpr
dented number of fine churches built, is due to the work of
men as Charles J. Connick, Nicola D'Ascenzo, Henry W
Young, J. Gordon Guthrie, Lawrence Saint and Joseph
Reynolds.

In metal work, there has been the greatest advance in ironw
and jewellery. Samuel Yellin is doing some masterly work
iron, as well as Frank L. Koralewsky, Morgan Colt and
Marie Zimmerman. In quality of design and technique,
standards have been reached by such jeweller-craftsmen
Frank Gardner Hale, Edward E. Oakes, Herbert Kelley,
Margaret Rogers, Mrs. Josephine H. Shaw, Mrs. Eda Lord Di
and Horace E. Potter. The early American silversmiths car
their art to a high point of perfection, and those of the pres
generation have been content to follow along the Colonial li
without attempting much originality or change. American si
is characterised by good lines and plain surfaces, with
decoration than is usual in Europe. The marked increase in
demand for handwrought silver is due to the notable work
Arthur J. Stone, George C. Gebelein, James T. Woolley, Ge
E. Germer (who has done some fine ecclesiastical pieces), Doug
Donaldson, George J. Hunt, Porter Blanchard, Karl F. Leino
John P. Petterson and F. J. R. Gyllenberg. A growing dema
for pewter is recently apparent, stimulated by the work of Les
H. Vaughan.

The leading American woodcarver is undoubtedly I. Kir
mayer, who has developed a style of his own which he ca
American Gothic, characterised by the introduction of archit
tural motives in the drapery, but more especially by strength
character, reverence and a mastership of all the best traditio
In furniture, as in silver, there has been a harking back
Colonial times, and the standards of public taste have be
raised enormously through the great vogue of antique pieces a
good modern reproductions. No new styles have been develop

In textiles the advances have been largely in batik and blo ating. The names of Miss Lydia Bush-Brown, Miss Helen yden, Charles S. Todd, Jean Paul Slusser, Arthur Crisp, Miss ll Witters, Gilbert Fletcher and Mrs. Marion Maercklein odbridge stand out prominently. Weaving has been restricted gely to Colonial models.

reditable work is being done in pottery. The porcelains of s. Adelaide A. Robineau and the tiles of Henry C. Mercer and s. Mary Perry Stratton have a high reputation. Other master ters are Charles F. Binns, Arthur E. Baggs, Edmund de Curtis, H. Varnum Poor and R. Guy Cowan.

ome excellent illumination has been done by Sister Olive nces, Sister Magdalen, Miss Winifred M. Crawford and Mrs. rtrude S. Bassett. The demand for hand bookbinding must ays be limited, but good work was done by Miss Mary Crease rs, Mrs. Averill Cole Howland, John F. Grabau and Miss anor I. van Sweringen. In the field of fine printing and ography it is generally conceded that such men as Bruce gers, D. Berkeley Updike, and T. M. Cleland are among the ders. The demand for good commercial printing and binding stimulated many of the leading publishers to put out books really artistic merit. American craftwork is holding its own h that of Europe and, in comparison, its dominant characistics seem to be its conservatism and restraint.

(H. P. M.)

HANGAR: *see* AERODROME.

HANIHARA, MASANAO (1876–   ), Japanese statesman, s born in Yamanashi-Ken. He graduated from Waseda Unisity, Tōkyō, in 1897 and entered the diplomatic service. In 9 he went to the legation at Seoul (Korea), as attaché, being nsferred to Washington in the same capacity in 1901. After ear of service there, he was made secretary, invited specially study American affairs, and later became chief secretary for eign affairs. He felt that American-Japanese relations were satisfactory and wished to impress upon the citizens of the ited States the necessity for friendly co-operation with the anese. He was sent to San Francisco as consul-general in 6, remaining until the end of 1917. Returning to Tōkyō he t became director of political affairs and then, in 1919, Viceister for Foreign Affairs. As vice-minister he was one of the r delegates to the Washington Conference 1921–2. In 1923 was appointed Japanese Ambassador to Washington, and it naintained in America that his reference, in a public speech, to " regrettable consequences which would follow the passage " the Immigration bill, was responsible for the bill becoming . The Japanese Govt., realising that some blunder had been de, recalled Hanihara in 1924.

HANKOW, China (*see* 12.919).—A great commercial entrepôt is vided for China by the three large cities, Hankow, Hanyan l Wuchang, at the point where the Han flows into the Yangtze ing. The population was given in 1923 as 1,646,800. In sumr the surrounding country is flooded, and vessels drawing ft. can get up to Hankow, but during the winter the port is essible only to vessels drawing 12 ft., even at favourable peri, and as the water falls hulks are moved out from the banks, h which they are connected by staging. In 1921, however, a er commission was formed, and the work of levelling the river l from Hankow downstream was begun. The advisability of d prevention works is also being investigated. Hankow, ing to its strategical importance, suffered considerably during Revolution of 1911, and in Nov. two-thirds of the city was troyed by fire, as a result of bombardment by the Imperialists. 1914 80% of the area was again covered with houses on the old tern. Several new roads, however, have since been laid out the rear of the native city on reclaimed land, and a scheme housing large numbers of the poorer classes on new areas, to eve the housing problem, has been promulgated.

he industrial development of the district, increasingly active er the World War, is reflected in the building of a number of tories and workshops, and foreign interests are largely inased. The British Bund has become the banking and comrcial centre, and a number of imposing banks and offices have n erected, including a customs house, a large Chinese hospital in European style in the native quarter, and a church in the French Concession. The British Concession has been enlarged, and the concessions, each with its own municipal council, now extend for over 2 m. along the river. Those of the Germans and Russians have been taken over by the Chinese authorities. The water supply of the city is good; and there have been no recent outbreaks of cholera. After the World War trade expanded steadily, though the black tea trade, Hankow's staple industry in former days, has declined, largely because of the elimination of the Russian market. The interruptions to communications and the constant impositions which have resulted from the internal troubles of China, as also the increased competition since the re-entry of German traders, have greatly troubled exporters.

HANN, JULIUS (1839–1921), Austrian meteorologist and climatologist, was born near Linz, Upper Austria, March 23 1839. In 1865 he became editor of the *Zeitschrift der Oesterreichischen Gesellschaft für Meteorologie*, and from 1877 was occupied in the Central Meteorological Institute at Vienna. In 1873 he was appointed professor of physics at the University of Vienna. He acquired a world-wide reputation for his works on atmospheric dynamics and thermodynamics, the " atmospheric pulse," cyclones and climatology. His principal works are *Die Erde als Ganzes; Die Atmosphäre und Hydrosphäre* (1872); *Handbuch der Klimatologie*, 3 v. (1908); *Lehrbuch der Meteorologie*, 3d ed. (1914) and many papers in his own *Zeitschrift* and the reports of the Akademie der Wissenschaften. He died in Vienna Oct. 1 1921.

HANUSCH, FERDINAND (1866–1923), Austrian politician, was born Nov. 9 1866 in Oberndorf, Silesia, the son of a poor Silesian weaver. After a childhood of crushing poverty, Hanusch became in 1900 secretary of the Austrian Textile Workers' Union. In 1907 he entered Parliament as a deputy. He was a pioneer of the Austrian trade union movement, especially in his own branch of industry, and did much to improve conditions for this class of labour, which were abnormally bad. In Oct. 1918 he became secretary of state in the new ministry of social welfare, and was author of most of the social legislation of the period, including the eight-hour day, the Works Councils Act, the law compelling employers of 14 hands or more to increase their staffs by 20% in order to reduce unemployment, and the laws dealing with the unemployment dole. He was universally respected for his personal probity and first-hand knowledge of labour problems and conditions. He died Sept. 28 1923.

HARA, TAKASHI (1856–1921), Japanese politician, was born at Morioka. After studying law and practising journalism he entered the diplomatic service, and was *chargé d'affaires* in Paris in 1886. In 1892 he was appointed director of the commercial bureau at the Foreign Office, and in 1895 became Vice-Minister of the department. He acted as minister to Korea from 1896–7, when he became chief editor of the Osaka *Mainichi*. Still deeply interested in politics he became the leading spirit of the Seiyu-Kai (Liberal) party. From the end of 1900 to May 1901 he was Minister of Communications in the Ito Ministry. He then reverted to journalism, and became chief editor of the Osaka *Shimpo*, and was elected a member of the House of Representatives for Morioka in 1902. Definitely abandoning journalism he was appointed Minister for Home Affairs in the first Saionzi Ministry of 1906, in the second Saionzi Ministry of 1911 and in the Yamamoto Ministry of 1913. On Sept. 29 1918 Mr. Hara, as the first commoner to become Prime Minister of Japan, formed a Cabinet based, for the first time in the history of Japanese politics, on strictly parliamentary principles. He was assassinated by a demented youth in Tōkyō on Nov. 4 1921.

HARBORD, JAMES GUTHRIE (1866–   ), American soldier, was born at Bloomington, Ill., March 21 1866. He graduated from the Kansas state agricultural college, Manhattan, Kan., taking the degree of B.S. in 1886. He joined the 4th Infantry in 1889 and was commissioned in the cavalry in 1891. Serving in the 5th, 11th, 10th and 1st Cavalry, he became a major in 1914. From 1903 to 1914 he served in the Philippine Constabulary. He became brigadier-general in 1917, and was chief of staff of the American Expeditionary Force in France 1917–8. He commanded the Marine Brigade near Château-Thierry, June 1918, being appointed major-general on June 26. He commanded the 2nd Div. A.E.F. in the Soissons offensive under Mangin, July 1918, after which he was placed in command of Service of Supply. He was reappointed chief of staff A.E.F., May 26 1919, and was head of the American military mission to Armenia, Aug. 1919. He served as deputy chief of staff, U.S. Army, 1921–2. Retiring from the army Dec. 29 1922, he became president of the Radio Corporation of America.

HARCOURT, LEWIS VERNON HARCOURT, 1ST VISCOUNT (1863–1922), British politician, was born in London Feb. 1 1863, the elder son of Sir William Harcourt (*see* 12.939). He was educated at Eton and afterwards travelled widely, becoming well known for his interest in art. In 1899 he married the only daughter of Walter H. Burns, of New York. In 1904 he was elected Liberal M.P. for the Rossendale division of Lancs., retaining the seat until 1916, and on the formation of Sir Henry Campbell-Bannerman's Government (1905) he became First Commissioner of Works. In 1910 he became Secretary of State for the Colonies in the Asquith Cabinet, and on the formation of the Coalition Government in 1915 again became First Commissioner of Works. In 1917 he was raised to the peerage. He died in London Feb. 24 1922, leaving a young son who succeeded to his title.

HARDIE, JAMES KEIR (1856–1915), British politician, was born on Aug. 15 1856 at Legbrannock in Lanarkshire of very poor parents. He was a message boy at six, and at 10 a "trapper" in a mine. After 13 years underground he became a miners' agent and helped to form the Ayrshire Miners' Union which was the first organised body to put forward the demand for a Labour party. In 1888 he stood as Labour candidate for Mid-Lanark and in the same year formed the Scottish Labour party. In 1892 he was elected for West Ham as the first Independent Labour M.P. At the formation of the Independent Labour party in 1893 he was made chairman, and eventually succeeded, with James Ramsay MacDonald, in forming the Labour party. He lost his seat in 1895, but was returned for Merthyr in 1900, 1906 and 1910. In 1894 he founded *The Labour Leader*. In 1908 he made a tour of the world. As a begetter of the Labour party and on account of his personality and courage he is considered one of the party's heroes. He died in Glasgow on Sept. 26 1915.

HARDINGE OF PENSHURST, CHARLES HARDINGE, 1ST BARON (1858–), British diplomat, was born in London June 20 1858, second son of the 2nd Viscount Hardinge. He was educated at Eton and Trinity College, Cambridge, and in 1880 entered the diplomatic service. He became secretary of legation at Teherān in 1896, and in 1898 went to St. Petersburg as secretary of embassy. In 1903 he returned to England and became assistant Under-Secretary for Foreign Affairs, becoming later (1906–10) permanent Under-Secretary. In the latter capacity he accompanied King Edward VII. on his foreign visits. He was created K.C.M.G. in 1904, G.C.M.G. in 1905 and K.G. in 1916. From 1904 to 1906 Sir Charles Hardinge was ambassador to Russia, and in 1910 was appointed Viceroy of India and raised to the peerage. Lord Hardinge returned to England in 1916 and was reappointed to the post of permanent Under-Secretary of Foreign Affairs. In Nov. 1920 he succeeded Lord Derby as ambassador in Paris, retiring in 1922.

HARDING, WARREN GAMALIEL (1865–1923), 29th President of the United States, was born at Corsica (then Blooming Grove), Morrow co., Ohio, Nov. 2 1865, son of George Tyron Harding, a farmer and country doctor, and Phebe Elizabeth Dickerson. He studied in the common schools, and from 14 to 17 at the Ohio Central College at Iberia. He taught in a country school for a year, read law for a short time, worked in a newspaper office and in 1884 became editor and proprietor of the *Marion Star*. On July 8 1891 he married Florence Kling. Having attracted the notice of Senator Joseph B. Foraker (*see* 10.628), he was encouraged to enter state politics, and was early recogni as an effective speaker. He served two terms in the Ohio sen (1900–4), and during the second was influential in secur Senator Foraker's re-election to the U.S. Senate. From 1904 1906 he was lieutenant-governor of Ohio, but in 1910, wh nominated for governor by the Republicans, was defeated b plurality of 100,000. In the campaign of 1912 his paper support President Taft. In 1914 he defeated Foraker in the Republi primaries as candidate for the U.S. Senate, and was elected w a majority of 100,000 for the term of 1915–21; but his friends with Foraker remained unabated.

In 1916 Mr. Harding was delegate-at-large from Ohio to t Republican National Convention, of which he was chosen p manent chairman. In the Senate he was regarded as a "saf man, who could be relied upon to support orthodox Republi policies. In 1915 he urged "preparedness" for naval defe In 1916 he voted against the confirmation of Louis D. Bran as associate justice of the U.S. Supreme Court. In 1917 he g his support to the declaration of War against Germany, and a to all the War measures, including the Selective Draft a Espionage bills. He favoured the death penalty for spies, b after the War advocated amnesty for political prisoners. opposed the suggested Federal control of food and fuel. favoured the Prohibition Amendment, and voted for the V stead Act, enforcing War-time prohibition, over the Presiden veto. He favoured the anti-strike clause of the Cummins Ra way bill, and voted for return of the lines to their owners with a year after the end of the War. He was for exempting Americ shipping from Panama Canal tolls and also supported wom suffrage. He was opposed to the Covenant of the League Nations, holding that "either the Covenant involves a surren of national sovereignty and submits our future destiny to t League, or it is an empty thing, big in name, and will ultimat disappoint all of humanity that hinges its hopes upon it." voted for the Lodge reservations and also for the Reed reser tion that the United States alone should judge whether mat of direct interest to it should be brought before the League; finally he voted against ratification of the Treaty as submitt by President Wilson. He maintained that Americans sho show chief concern for America, and opposed all tendenc toward internationalism. He supported the Knox resoluti declaring that war with Germany was ended.

At the Republican National Convention in 1920 Mr. Hardi was not at first among the prominent candidates for preside On the first ballot he received $65\frac{1}{2}$ votes (493 being necessa for choice), 39 of these being from his own state. On the eigh ballot he received $133\frac{1}{3}$ votes, on the ninth $374\frac{1}{2}$ votes, and the tenth he secured the nomination with $692\frac{1}{2}$ votes, the res being due largely to the support of certain influential U.S. Se tors, delegates to the convention, who hoped that as presi he would be amenable to the Senate. He did not "stump" t country, but conducted his campaign from the "front porch of his own home. Mr. Harding based his campaign chiefly up criticism of the Wilson administration, denouncing especia the excessive power that, as he maintained, had been exercis by the executive as a result of War centralisation; he demand as speedy as possible a return to normal conditions, political a industrial.

While opposing the Covenant of the League of Natio Mr. Harding gave to many of his supporters the impression th he desired an "association of nations" which, without t characteristics of a super-state (such as he believed the Leag to be), might safeguard peace. But he retained the politi support of many who were opposed, like Senators Borah a Johnson, to any sort of international association. In the N elections he won an overwhelming victory over James M. C the Democratic nominee, also from Ohio; he carried, genera by immense majorities, all the northern states and all but of the states on the border between North and South, and cut down materially the Democratic majorities in the Sou The electoral vote was 404 for Harding against 127 for C The popular vote was 16,138,000 for Harding against 9,142, Cox. In Ohio the popular vote was 1,182,000 for Harding inst 780,000 for Cox. The sweeping character of his victory s due less to his own personal strength or to the weakness of x than to the national reaction against the Democratic party l the popular feeling against President Wilson. Mr. Harding igned from the U.S. Senate in Dec. 1920, and was inaugurated irch 4 1921, the sixth President to come from Ohio.

The promise frequently made by Republican campaign leaders t Mr. Harding would surround himself with advisers of acity and experience, seemed to be fulfilled by his choice of inet members. The outstanding names were those of Charles Hughes and Herbert C. Hoover, who became Secretary of te and of Commerce respectively. The distinguished career the former and the widespread confidence in his ability and itical integrity had marked him for the most important posi- n in the Cabinet; and there had been a general demand that new administration should utilise the organising ability played by Hoover in many fields. Various elements in the publican party, nevertheless, had stoutly opposed their pointment, so that the President's choice showed that he was pared to exert his independence of party managers and to ist upon administrative efficiency. The choice of Andrew W. llon, a wealthy banker and ironmaster of Pittsburgh, as retary of the Treasury, was welcomed by men of business; l though that of Will H. Hays to be Postmaster-General was he nature of payment of a political debt to the man who had n the manager of the Republican campaign, it was early tified by his administration of the Federal postal service.

Mr. Harding's inaugural address, and his first message to ngress, delivered in person on April 12, voiced his desire to urn to "normalcy," as he expressed it. Retrenchment in enditure formed a major item in his programme, together h a prompt and thorough revision of taxation. He advocated adoption of a national budget system, and the Congress hav- passed a Budget bill similar to that vetoed by Mr. Wilson in o, he approved it on June 10 1921; it provided for a Budget reau in the Treasury Department and the appointment of a ctor of the budget, the first being Charles G. Dawes, formerly eral purchasing agent of the American Expeditionary Force. sident Harding's first budget was presented Dec. 5 1921. President was insistent upon the need of repealing the excess fits taxes and reducing transportation taxes and income sur- es. The need of financial retrenchment led to his opposing proposal that War veterans should receive a cash bonus. In matter, as in others, he proved his ability at this early stage esist political pressure. As regards the tariff he advocated, as mporary stop-gap, the passing of the emergency tariff, which been vetoed by President Wilson, but which with slight ration was approved by Mr. Harding on May 27 1921. He ed the need of adopting a permanent tariff policy, and on 5 1921 suggested a "flexible tariff" which might provide the adjustment of rates to meet unusual and changing con- ons. Such adjustments might be made, in his opinion, by executive on the advice of the Tariff Commission.

Ir. Harding's interest in agricultural problems was keen; in first message he asked special protection for agricultural rests, and in his second he declared that something more n protection must be given the farmers, advocating warmly encouragement of co-operative marketing plans. As regards nestic legislation, the President, in general, assumed the rôle noderator. He disclaimed any desire to enlarge the powers responsibilities of the executive, which, he declared, were ady too large; and he aimed at close co-operation with Con- s. In marked contrast to his predecessor, he left adminis- ive responsibility to the members of his Cabinet. Foreign cy was largely determined by Hughes, financial by Mellon, the problem of unemployment was thrown upon Hoover. President, however, frequently played an active rôle in the erences necessary to secure general agreement, as on Aug. 21 when an accord was reached between the Treasury and Representatives on the taxation plan.

he foreign policy of the administration at first seemed likely to emphasise independence of action, on contradistinction to that of President Wilson; the threatened war between Panama and Costa Rica was prevented by a sharp note from Secretary Hughes; the claims of the Japanese to a mandate over Yap were stoutly denied; the administration refused to follow Great Britain in resuming trade relations with Soviet Russia. President Harding made plain in his first message that the United States would not enter the League of Nations. But he expressed himself warmly in favour of active co-operation with other nations of the world, and by accepting the invitation to participate in inter-Allied councils indicated that he would avoid a policy of isolation. In rejecting the League Covenant, he said "we make no surrender of our hope and aim for an association to promote peace, in which we would most heartily join." The President advocated a declaration of peace with Germany by resolution, and the immediate negotiation of a treaty. This policy was adopted by Congress, which agreed upon a joint peace resolution, signed by him on July 2. On Aug. 25 1921, a treaty with Germany was signed, embodying the President's plan of including most of the stipulations of the Versailles Treaty, but repudiating adherence by the United States to any clause referring to the League of Nations. This treaty and similar pacts with Austria and Hungary were ratified by the Senate, Oct. 18 1921.

The most important step taken by President Harding during the first year of his administration was the calling of an international conference on the limitation of armaments. On May 25 1921 the Senate had adopted an amendment of Senator Borah to the Navy bill, authorising and inviting the President to call such a conference. Mr. Harding's preliminary invitations to the principal naval Powers (Great Britain, Japan, France and Italy) were sent July 10, and formal invitations Aug. 11. He made clear his belief that the question was closely connected with the problems of the Pacific and Far East, and invitations were also sent accordingly to China and to the smaller European Powers with Far-Eastern interests—Holland, Belgium and Portugal. The invitations were accepted, and the conference assembled at Washington on Nov. 12. President Harding avoided the example set by his predecessor, and did not himself participate as a delegate. He displayed his political tact in the choice of the American delegation, which was led by Secretary Hughes and included, besides Elihu Root, two members of the Senate, Lodge and Underwood, the Republican and Democratic leaders respectively. The policy drafted by the President and Mr. Hughes was direct and vigorous. They refused to permit the vital problem of limitation of armaments to be side-tracked, and surprised the conference by proposing a 10-year naval holiday and a drastic scrapping of tonnage by the three chief naval Powers. The President made it clear that he regarded the conference merely as a step in securing international understanding and goodwill; he advocated the convening of succeeding conferences as a possible means of securing an international association for the promotion of peace, and he approved the principle of substituting an understanding between the United States, Great Britain, France and Japan regarding Far-Eastern problems, for the existing Anglo-Japanese Treaty. (*See* WASHINGTON CONFERENCE.)

The Washington Conference was the highwater mark of the Harding Administration. Thereafter he faced the development of blocs in the Republican party which destroyed its solidarity, and the growth of criticism which was manifested by the elections of 1922, as a result of which the Republican majority in the House was reduced. Mr. Harding's veto of the Bonus bill indicated his unwillingness to sacrifice principle to expediency. But he found difficulty in explaining the administrative incompetency, or worse, of office-holders in Washington; resentment was felt against the Republican national organisation controlled by the Old Guard; there was outspoken criticism of the new tariff; keen discontent among the farmers led to the election to the Senate of Shipstead and Magnus Johnson. Again the threat of a Third party became imminent.

In the summer of 1923 Mr. Harding set forth on a tour across the United States and to Alaska, designed to reassure the farmers and reawaken enthusiasm for the Administration. The President, already tired, became ill on the trip back from Alaska and was stricken with pneumonia in San Francisco. On Aug. 2 1923 he died suddenly. (C. Sey.)

HARDY, THOMAS (1840–), English novelist (*see* 12.946); in later years received increasing recognition, not only as a great novelist but also as a poet. His great epic-drama *The Dynasts* (1904–8), a chronicle play of England's struggle against Napoleon, with an accompaniment of philosophic comment chanted by a chorus of "phantom intelligences," was in part produced at the Kingsway Theatre, London, in the early months of the World War, and again at Oxford in 1920. several volumes of lyrical poetry followed (*Selected Poems* in 1916; *Collected Poems* in 1919—but now incomplete). His first wife died in 1912, and in 1914 he married Florence Emily, daughter of Edward Dugdale, herself a writer of children's books and articles in periodicals. Both on his 70th and on his 80th birthday he received tributes of respect and admiration throughout the English-speaking world.

Thomas Hardy's career naturally divides itself into three periods. The first of these contains his work as a novelist, and ends with *Jude the Obscure* in 1896 (*The Well-beloved*, published in book form in 1897, appeared serially in 1892). The second period consists of *The Dynasts*, the three parts of which were issued separately in 1904, 1906, 1908: no doubt the greatest single achievement of his career. The third period may be said to begin with *Time's Laughing-stocks* in 1909, and is wholly devoted to lyrical poetry. It is not often that an artist's life can be divided so definitely into separate stages, each stage characterised by the use of a different form; and, next to its length and plenty, and consistently noble idiosyncrasy, this tripartite division is perhaps the most remarkable feature of Mr. Hardy's career as a whole. The lyrical period, however, does not give us an entirely new development of his genius.

While he was writing novels, he had occasionally experimented with poetry, and some of the results were published, in *Wessex Poems* (1898) and *Poems of the Past and the Present* (1901), between *Jude the Obscure* and *The Dynasts*. The volumes published since *The Dynasts* also contain a good many more of these earlier poems. But from 1909 onwards Mr. Hardy wrote nothing but lyrical poetry, and this may therefore truly be called his lyrical period. (*A Changed Man* in 1913 merely rescued from the periodicals of former years several stray pieces of minor fiction.) It represents a new concentration of his power, but certainly no diminution of it. Devotion to lyrical expression has produced a mastery almost as signal in its kind as his command of the art of fiction; and his 70th year saw him beginning, with *Time's Laughing-stocks*, the series of volumes—*Satires of Circumstance* (1914); *Moments of Vision* (1917), *Late Lyrics and Earlier* (1922), *Human Shows, Far Phantasies* (1925), which has shown him to be the most original, the most poignant, and also the most copious, of contemporary lyrical poets.

The originality of the technique in these volumes does not by any means consist in a mere breach with the accepted conventions, but rather in its highly individual—to some, perhaps, rather disconcerting—compound of the conventional and the unconventional. Most of these lyrics maintain an exact and even rigid formality of stanza, in which a scheme of rhymes is imposed, as it seems, arbitrarily and at all costs. The effect is sometimes justified by its music; but more often by the compact force its pressure gives to language almost conversational in its idiom and choice of words. Yet the diction which defies poetic tradition and seems to despise the magic of elaborated verbal suggestion, is oddly blended with stiff literary phrases and even with words that one might expect only lexicographers to think of. The truth seems to be that, in lyrical technique, Mr. Hardy has no prejudices either for or against the conventions. He is simply concerned with the matter which intense feeling and profound understanding have enabled him to imagine in a way peculiarly his own, and to express this faithfully he has forged a technique peculiarly his own, out of whatever the language of literature or of speech could offer him. Readers who are willing to allow him this liberty can hardly fail to be impressed, perhaps nowhere else in recent poetry, by the subtlety, dep and variety of his versions of the experiences common to h manity: the commonplace becomes in his hands something ri and strange. Naturally the habit of thought and outlook the world, which we find progressively insistent in the series the Wessex novels, and which inspire the turbulent matter a monumental structure of *The Dynasts*, are very evident also the lyrics; which indeed are often in the nature of marginal co ments on themes previously used.

But something like the quintessence of his tragic power m be found in such ballads as "A Trampwoman's Tragedy," such keen discrimination of pathos as "Near Lanivet," a something too like the quintessence of his irony to be altogeth comfortable in *Satires of Circumstance* or "Ah, are you diggi on my grave?" Nor is the rustic humour of his beloved Dors villagers wanting, nor the vivid delight in nature, in the extra dinary range of his lyrical art. It is, in fact, the same Har in the lyrics as in the novels and *The Dynasts;* but a Hardy wh if his lyrics were all we had of him, would surely, by virtue them alone, hold a secure, indeed a unique, position in mode English literature. (L. Ab.)

HARE, SIR JOHN (1844–1921), British actor (*see* 12.948), di in London Dec. 28 1921. He made his latest appearance on t stage in a revival of Grundy's *A Pair of Spectacles* at Wyndha Theatre in 1917.

HARINGTON, SIR CHARLES HARINGTON (1872– British soldier, was born at Chichester May 31 1872 and co missioned in the King's (Liverpool) Regiment in 1892. A service in the South African War, he held a series of staff a pointments, and on the outbreak of the World War went France as general staff officer, 2nd grade, of the III. Corps. ability brought him rapid promotion and in June 1916 he bec major-general, general staff of the II. Army. He remained ch of staff to Gen. Plumer in France for nearly two years, w the exception of a short interval in Italy. The combined tal of the two men were such that the II. Army became prover for its excellent staff work and for carrying out any operation w the maximum economy of life. Messines 1917 was perhaps th most brilliant feat. In April 1918 Harington was recalled to War Office to become deputy chief of the Imperial Gen Staff. In the following year he was created Knight comma of the Bath. In Sept. 1920, he succeeded Gen. Milne as C mander-in-chief of the British forces, and subsequently of Allied forces at Constantinople and in the Black Sea. His and diplomacy in a difficult situation, especially during Chanaq incident, helped to avert serious complications, and fittingly acknowledged in Parliament. On his return to Engl in Oct. 1923 he was appointed to the Northern Command.

HARLAN, JOHN MARSHALL (1833–1911), American ju (*see* 12.954), died in Washington, D.C., Oct. 14 1911.

HARPIGNIES, HENRI (1819–1916), French painter (13.15), of whose drawings there was an exhibition in Lon in March 1910, died in Burgundy Aug. 25 1916.

HARRIGAN, EDWARD (1845–1911), American actor (13.17), died in New York City June 6 1911.

HARRISON, FREDERIC (1831–1923), British man of lett (*see* 13.23). Frederic Harrison's death at Bath from sud heart failure at the age of 92, on Jan. 14 1923, closed an unusu long and active career devoted to literature and religious serv

In his last book *De Senectute* (1923), which he did not liv see published, he re-affirmed his life-long principle and attachm to the religion of Auguste Comte, and no estimate can do justice which does not take into account the essentially relig character of his life, of which all his written works may be to be a contributory expression. Though Frederic Harris originally came into prominence in the days (1850–80) of figh agnosticism, he was never himself an "agnostic," and in fact severely criticised by the leading agnostics, notably by Hu and Herbert Spencer, etc.; moreover, as a Positivist, he w republican in spirit and, what was new at that period, a soci gist. It was this positivist sociology which caused him as a you an to espouse the cause of trade unionism, which he did with ch energy and legal skill as adviser to the Royal Commission Trade Unions in 1867, that he was really the inspirer and under of the trade union law as it existed from 1868 to 1906. one the less, his religion did not permit him to embark upon a iblic career. He virtually retired from politics (in the party nse) and from legal practice in mid-life, this latter very largely the enforced consequence of his pioneer fight on behalf of ide unionism, and took to letters.

At the age of 80 he published his *Autobiographic Memoirs,* vol. (1911). Among the books that flowed almost annually m his pen may be mentioned: *Memories and Thoughts* (1906); *itional and Social Problems* (1908); *Tennyson, Ruskin, Mill d other Literary Estimates* (1899); *George Washington, etc.* 901); *The Creed of a Layman* (1907); *Realities and Ideals* 908); *Novissima Verba* (1920); *De Senectute* (1923). As an storian Frederic Harrison did not belong to the modern school specialisation, and ranks as a " literary-historian "; as essay- , he excelled, occupying a distinguished place both for the undness of his judgment and for the vigour and clarity of his yle. Politically, he stood in the position of an unofficial pro- nsul, and for some years before the World War he repeatedly irned his countrymen of the impending crisis arising out of the med system of Europe, and of the necessity of British prepara- on to meet it. An article he wrote in *The English Review* in 13 proved to be only too prophetic. During the War he stood falteringly for victory and for the cause of France. His son, né, was killed in Flanders in 1915.

Frederic Harrison can hardly be classified either as a pure in of letters or as politician by virtue of his religious opinions iich debarred him from active participation in worldly affairs, d even as a critic the humanist motive was uppermost. His e may be described as an attempt to introduce Comte's Human- sociology into this country, to which end he devoted all his ergies. For 20 years he was the leader of English Positivism d regularly lectured at Newton Hall, being also a co-founder of d contributor to *The Positivist Review*. His political views were llously put forward in that organ. He was not a Radical in e party sense though always a Liberal in spirit. Internationally, was a life-long supporter of France, and in 1870 vehemently ged British support of Gambetta as against Bismarckianism. he was a " Little Englander," it was because of his champion- ip of the " Little Peoples," and during the Boer War his pro- unced anti-jingoism led him into acute controversy. Publicly, attitude was often misunderstood for that reason. He may said to have been a republican in spirit, a humanist by con- tion and a " meliorist " as politician.

Frederic Harrison had not originally wished to found a Posi- ist centre or sect, but after the secession of Dr. Congreve on e crucial issue of allegiance to French Comtists, he virtually d no alternative, and it was thus that Newton Hall came into ing. As the head of that body, Frederic Harrison found copious e for his scholastic knowledge and energies as lecturer and cher, and though in that position he was " labelled," the cerity and disinterestedness of his opinions were so universally ognised that his public moral authority did not lose through lation. In this way he occupied a kind of " chair " of public orals, such as is hardly conceivable in any other country, hence unflinching war determinism in 1914 caused him to be ore popularly known and appreciated in extreme old age than d been the case during the Victorian epoch when, as a human- , he found himself neither on the one side nor the other of the eat Victorian struggle for " liberty of thought," the founda- n of which intellectually had been laid by Auguste Comte and arles Darwin.

In this great battle of " reason," which started at Oxford, Har- on played a conspicuous part, though never as an iconoclast d in interest, spiritually; *i.e.*, outside the intellectual ethicism sing out of the new criticism, for he neither adhered to the litarianism of Mill nor to the " dry light " of the debaters the famous Metaphysical Society of which he was a member. sitivism was at that time regarded as a " heresy " both by orthodoxy and by the agnostics, and in the controversies that ensued Harrison drifted somewhat out of the movements of his time. He was perhaps the last survivor of the " great " Victorians. He will be remembered as a supreme individualist, a slashing controversialist, as a practical idealist and citizen. Thus he consistently advocated the return of the " Elgin Marbles " to Greece on the ground that the statuary belonged to the historical religion of the Greeks. He was a friend of President Roosevelt and twice lectured in the United States. He was at his best as critic of life and art in the relation of the past to the present, which was Comte's " law " of continuity, but Harrison was alive to the academic weaknesses in Comte's *Polity* and rejected any dogma. In his latter years he resided at Bath, of which city he was given the freedom. He refused all titles or " honours." His ashes, mingled with those of his wife, repose in an urn placed in the chapel of Wadham College, Oxford, according to his last wishes. See Austin Harrison, *Frederic Harrison: Thoughts and Memories*, 1925. (A. Hn.*)

HART, SIR ROBERT (1835–1911), Anglo-Chinese official (*see* 13.30), died at Great Marlow, Bucks., Sept. 20 1911.

HARTLEPOOL, England (*see* 13.34), had a population (1921) of 20,997 and an area of 924 acres. It is connected with West Hartlepool by rail and tramway over Hartlepool Bay. West Hartlepool had in 1921 a population of 68,689 and an area of 2,958 acres. The parish church was restored in 1921, and the Baptist church, destroyed by bombardment, was rebuilt. An obelisk has been erected in Victory Square, West Hartlepool, as a war memorial. In 1924, 5 ac. of land were levelled for additional timber storage, and a quay was built for the fishing industry in 1910. The total area of docks in the Hartlepools is now 200 acres. In Dec. 1914 the towns were shelled by German cruisers and a little damage was done.

HARTLEY, SIR CHARLES AUGUSTUS (1825–1915), British engineer (*see* 13.35), died in London Feb. 20 1915.

HARTLEY, JONATHAN SCOTT (1845–1912), American sculptor (*see* 13.35), died in New York City Dec. 6 1912. Among his last exhibits were " Young Hopi Stick Thrower " (1911) and " The Cradle of Pan " (1912).

HARVARD UNIVERSITY (*see* 13.38).—The history of Harvard University after 1909, when Abbott Lawrence Lowell succeeded Charles William Eliot as president, is one of change and growth to meet new needs and opportunities.

Buildings.—Three residence halls for freshmen (Gore, Standish and Smith) accommodating about 450 men, built near the Charles river at a cost of approximately $2,500,000, were opened in 1914; and in 1919–20 a number of other dormitories, originally erected by private enterprise, were purchased by the university, thus largely increasing the residence halls under its control; in 1924–5 over half the undergraduates of Harvard College and a considerable proportion of the students in the graduate schools located in Cambridge were housed in buildings owned by the university. In 1925–6 Massachusetts Hall, which was a residence hall from 1720 to 1870, was again occupied by students, and two new dormitories, Lionel and Mower halls, became available for seniors; the erection of a third dormitory in the Yard was begun, while by the Charles river a fourth large dormitory for freshmen was under construction. Two new chemical laboratories, the Wolcott Gibbs and the Thomas Jefferson Coolidge, Junior, Memorial, were opened in 1913–4; these facilities for the study of chemistry were, in 1925–6, being increased by large laboratories, which at time were under construction at a cost of approximately $2,000,000.

During 1914–5 the university's museum buildings as originally planned by Louis Agassiz in 1859 were completed by an addition to the Peabody Museum. A building for the Music Dept. and the Cruft High-Tension Laboratory were also opened in 1914–5. In the same year the Widener Library, the largest of college libraries, erected by his mother in memory of Harry Elkins Widener, of the class of 1907, who lost his life in the " Titanic," was first used. The Germanic Museum, to exhibit the evidences of Germanic civilisation in the widest sense, was completed and opened in 1921. The new Counting-House, finished in 1925, provides adequate offices for the officials, except the treasurer, who have charge of the university property and accounts. In the same year work was begun on the buildings for the Graduate School of Business Administration, provided through the gift of $5,000,000 by George F. Baker; these buildings occupy a large tract on the Boston side of the Charles river. The erection (1925–6) of a new Art Museum at a cost of $1,200,000 to take the place of the Fogg Museum, long outgrown, was also made possible by friends of the university. Improvements have been made in athletic fields, gymnasia, etc.

Endowments.—The period under consideration was remarkable for the rapid increase of funds. In spite of the World War, graduates and friends gave approximately $17,000,000 in the decade 1909–19. Of this about $5,000,000 was for buildings and immediate use; $12,000,000 for permanent endowment. With the close of the World War the alumni revived a project, started before the War but then suspended, to secure additional endowment, and organised in 1919 a committee for the purpose. At the close of the fiscal year 1924–5 over $14,000,000 had been subscribed, of which over $12,875,000 had been paid into the treasury. The total productive endowment of Harvard University on the same date was approximately $70,000,000.

New Plan of Admission.—In 1910–1 a new plan of admission to Harvard College was adopted, which endeavours to test the intellectual condition of the applicant for admission and to establish a closer co-operation with preparatory and high-school authorities. From experience the plan is found to secure closer articulation, especially with public schools, and to provide the college with a better grade of student. In its essential features the "new plan" has been followed by a number of other important colleges. In 1923 the experiment was begun of admitting without examination students who have completed in regular course in a good secondary school a programme of study which fulfils in all respects the requirements for admission to the privileges of examination under the new plan, provided they have ranked in scholarship in the last two years of their school course among the highest seventh of the boys in the graduating class and are recommended by their school. So far as can be judged, students so admitted are above the average of their class in scholarship. In 1924, 48·4% of the freshman class entered from public schools.

The former free elective system, which furnished little or no direction to a student's choice of studies, was modified in 1910 by requiring each student to choose enough courses in one field of knowledge to enable him actually to gain considerable knowledge of that subject; and by distributing a certain number of courses among other fundamental subjects to secure a more systematic and well-rounded education. At the same time the "degree with distinction" was established for high attainment in general, coupled with distinguished success in the subject to which the student has given most attention. Beginning with 1916, general final examinations on the student's field of concentration were introduced in the departments of history, government and economics for all students; the plan was later extended to all other departments except the natural sciences.

In the years following 1916 a system of tutors was developed to direct the private reading of the students. The tutor meets his men individually each week and advises as to their private study; he is in no sense a coach. The results thus far show that the tutorial system is of great educational value; it encourages the student to think of his chief subject as a whole, and to read independently in his field; while the general final examination gives an opportunity to test his capacity at the end of his course. The two have resulted in increased interest on the part of the students and in higher scholarship among students of varying abilities. In 1925 out of the 516 students who presented themselves for the general final examinations in their several fields, 111, or 21·4%, obtained degrees with distinction.

The Engineering School.—In 1915–6, after the Massachusetts Institute of Technology had decided to move from Boston to Cambridge, all instruction in engineering was virtually transferred to it under a co-operative agreement entered upon between the Institute and Harvard. There being doubt, howeve
as to whether such co-operation was allowed under the terms
the Gordon McKay bequest which was given to Harvard Univer
sity to further applied science, application was made by th
university authorities to the Supreme Court of Massachusett
The decision of the court in 1917 was adverse, and Harvar
again established a School of Engineering Sciences, which, i
spite of conditions caused by the World War, made a successfu
beginning, and in 1924–5 had 36 instructors and 258 student
on the register.

Graduate Schools.—The period under review was marked b
constant developments in the graduate schools of the universit
The Graduate School of Arts and Sciences grew steadily i
numbers, although in common with other departments i
suffered a temporary check by the World War. Its students a
mostly preparing for careers as teachers and scholars; and,
spite of the economic disadvantages under which the professio
of teaching still labours, it is impossible to meet all requests com
ing to the school for teachers and research workers. In 1924
the total attendance was 763. The preparation for the scientifi
management of business given to young men by the Graduat
School of Business Administration won wide appreciation, caus
ing large resort to the school (614 in 1924–5) and it became ne
essary to limit the number of students. In the Law School
post-graduate year of study was established, leading to the de
gree of S.J.D., intended especially for men wishing to prepar
themselves for teaching law and for research in jurisprudenc
In 1924–5 the number of teachers was 24 and of students 1,20
representing 175 colleges. In the Medical School departmen
of pharmacology, of tropical medicine and industrial medicin
were organised, and a School of Public Health was establishe
Affiliation with hospitals, many of them grouped near the schoo
and changes in the faculties secured one of the largest and strong
est organisations for the teaching of medicine and for medic
research in the United States.

A separate faculty of architecture was established in 191
having under its charge the Graduate Schools of Architectu
and of Landscape Architecture, which respectively had (1924–
48 students from 19 colleges, and 39 students from 22 colleg
In 1920 the instruction in education, which had previously be
given under the faculty of arts and sciences, was organised
the Graduate School of Education with a separate faculty. T
this school women, as well as men, who hold an academic degr
are admitted, this being the only part of the university where c
education is recognised. In the year under review the school ha
37 instructors and 272 students, representing 86 colleges. T
Theological School was created in 1922 by an affiliation betwe
the Harvard Divinity School (1816) and Andover Semina
(1808); but this union was dissolved by a decree of court in 19
With the Divinity School are associated the Episcopal Theologic
School (in Cambridge), Boston University School of Theolog
and Newton Theological Institution. The degrees of Master
Theological Science (S.T.M.) and Doctor of Theology (Th.D)
were established for those wishing to continue their studi
after obtaining the ordinary degree, and the ordinary degr
itself (S.T.B.) is now given on the basis of a general examinati
at the end of the student's three-year course.

University Extension.—Subsequent to 1909 Harvard Unive
sity united with Boston University, Boston College, the Massach
setts Institute of Technology, Simmons College, Tufts Colleg
Wellesley College, the Boston Museum of Fine Arts, the Ma
sachusetts Board of Education and the School Committee
the City of Boston in offering courses in university extensio
These courses are given ordinarily in Boston to a considerab
number of students each winter.

War Services.—Ten thousand Harvard graduates and studen
entered the army or navy of the United States during the co
flict; of these 70% received commissions. No complete recor
exist of those who engaged in non-military service, but it m
safely be said that over half the Harvard men of every age to
an active part during the World War. The Roll of Honour co
tains 372 names of men who gave their lives.

The number of students in 1924–5 was as follows:—

College	3,009
Graduate School of Arts and Sciences	763
Special Students	32
Engineering School	258
Theological School	74
Law School	1,201
Medical School	506
Dental School	204
School of Public Health	30
Graduate School of Business Administration	614
Architecture	87
Graduate School of Education	272
Bussey Institution	25
Summer Schools of 1924 (446 deducted for duplication)	2,686
Total	9,315

1908–9 the corresponding total was 5,250. The number of ficers of instruction and administration in 1924–5 was 1,319; in 08 9, 743. The total number of volumes and pamphlets in the iversity library in 1924 was over 2,320,000. Radcliffe College or women), in which instruction is given by Harvard teachers, though not part of Harvard University, had in 1924–5 908 udents. (C. H. M.)

HARVEY, GEORGE BRINTON McCLELLAN (1864–), merican editor and diplomat, was born at Peacham, Vt., Feb. 1864, and was educated at the Peacham Academy. At the ge of 18 he became a reporter on *The Springfield* (Mass.) *Re-ublican*, and later on *The New York World*. In 1885 he was pointed by Governor Green of New Jersey as aide-de-camp his staff, and was reappointed by Governor Abbett. The tter also made him insurance commissioner of New Jersey in 90. During 1891–4 he was managing editor of *The New York orld*. Then for several years he was engaged in the construc-on of electric railways, and in 1898 organised a syndicate hich secured possession of the lines in Havana, Cuba. The llowing year he purchased *The North American Review*, which ereafter he edited for several years. During 1900–15 he was esident of the publishing house of Harper & Bros., and during 02–13 was editor of *Harper's Weekly*. In 1903 he purchased *he Metropolitan Magazine*.

Harvey was said to have been the first to suggest (in 1906) oodrow Wilson, then president of Princeton, as a presi-ntial possibility. In the campaign of 1912 he gave Wilson rong support; but after the latter's nomination an estrange-ent developed, due, as it was generally understood, to the ct that Wilson intimated that his cause was being jeopardised Harvey's officiousness. In 1916 Harvey urged the election Charles E. Hughes, the Republican candidate for President. e was strongly opposed to the League of Nations, on the ground at it involved the yielding of national sovereignty. In 1918 established *The North American Review's War Weekly*, later lled *Harvey's Weekly*, which bitterly denounced the Wilson lministration. In 1921 he was appointed ambassador to Eng-nd by President Harding, a position which he held till Nov. 23. He became editorial director of *The Washington Post* in May 24, resigning May 31 1925. Harvey's books include *Women* 08) and *The Power of Tolerance, and Other Speeches* (1911).

HARWICH, England (*see* 13.47), with a population of 13,046 1921, and an area of 1,541 ac., including Halstead, added to e borough in 1917, is the most important naval base on the st coast of England. Flotillas operating from the harbour did gnificent work during the World War, particularly in mine eeping in 1917. The main quay was extended by 1,000 ft. 1911, and there are now berths for nine steamers, and moor-gs for nine more in the river. A train ferry to Zeebrugge was ugurated in 1924. The parish of Dovercourt has been united th that of Harwich for purposes of local government. A metery was opened at Parkeston in 1910. The electricity ply was taken over by the municipality in 1925.

HAUPTMANN, GERHART (1862–), German dramatist e 13.68), hardly added to his reputation as a dramatist after 09. He produced *Kaiser Karls Geisel* (1908); *Griselda* (1909); *e Ratten* (1910), the latter in his earlier realistic manner; *Gabriel Schillings Flucht* (1912); *Das Bogen des Odysseus* (1914); *Winterballade* (1917); *Indipohdi* (1921) and *Peter Brauer* (1921). His novels include *Der Narr in Christo Emanuel Quint* (1910); *Atlantis* (1912); *Der Ketzer von Soana* (1918); *Phantom* (1923) and *Die Insel der Grossen Mutter oder Das Wunder von Île des Dames* (1924). In 1921 appeared *Anna*, an epic poem.

See C. Holl, *Gerhart Hauptmann*, etc. (1913); W. Bonsels, *Das junge Deutschland und der grosse Krieg, aus Anlass des Briefwechsels Romain Rollands mit G. Hauptmann über den Krieg und die Kultur* (1914); A. Esprey, *G. Hauptmann und wir Deutschen* (1916); P. A. W. Gaude, *Das Odysseusthema bei Hauptmann* (1916); J. H. Marschan, *Das Mitleid bei G. Hauptmann*, with bibliography (1919); Paul Fechter, *Gerhart Hauptmann* (1922).

HAVANA, Cuba (*see* 13.76).—The population of Havana, the capital of Cuba, was 360,517, according to the census of 1919. Since that time it is estimated that there has been a still further increase to perhaps 500,000 inhabitants in 1926, for which immigration, mainly Spanish, is largely responsible. Havana, once rather backward in civic improvements, now compares as favourably with other cities of the world in its attractive, up-to-date appearance as it does in commercial and industrial importance. Motor cars swarm the streets, which for the most part are very narrow, but this condition has been relieved by having traffic go one way in all but the wider thoroughfares. In keeping with the wealth of Cuba, the capital has an unusual number of splendid private residences, excellent hotels, and luxurious club houses. The Spanish clubs are astonishingly rich. One of them, the Galician Club, has 67,712 members, while the Asturian Club has 60,351. The university of Havana, the principal educational institution of Cuba, has over 4,000 pupils, of whom some 3,000 are in daily attendance.

Havana is the economic, as well as the political, social, and intellectual centre of Cuba. Nearly all of the larger commercial companies and banks have their main offices there. The volume of trade through the port of Havana surpasses that of any city in the Western Hemisphere, except New York. About 75% of all Cuban imports enter at Havana, but the proportion of exports is considerably less. The customs receipts at this port are some 75% of the total collected in the island. Havana is connected with other parts of the world by means of a number of steamship lines and cables. There is even through freight train service from the United States, making use of a ferry from Key West, which is six hours away. (C. E. Ch.)

HAVRE, LE (*see* 13.82), the second seaport of France, had a pop. of 163,374, including the garrison, in 1921. Work has been continued on the last stages of the 1909 programme of port improvement, which includes a large graving dock and wharfage in the tidal basin, a floating dock and pontoons, a basin for large oil tankers and reservoirs in the outer harbour, and a wharf and mole for goods storage in the north part of the port. A petroleum pipe-line to Paris has been built, but Havre is still only linked by one line of railway to the capital, and is badly connected with other towns in its own district. An escalator is to be built in Rue de Montmorency, one of the steepest streets. In Aug. 1924 a monument was unveiled commemorating the hospitality shown by the town during the War to the Belgian Government, which was housed in a hostel at St. Adresse to the northwest of Havre, after the fall of Antwerp. At the same time a golden sword of honour was presented to the King of the Belgians on behalf of the French people. During the World War large numbers of British and American troops and vast quantities of ordnance and stores passed through the port, and after the Armistice it formed one of the American embarkation points. Trade has again reached its highest pre-war point. In 1924, 4,021 vessels of 8,264,645 tons entered and cleared the port, as compared with 4,018 vessels of 5,671,975 tons in 1907, previously the highest figures recorded.

HAWAII (*see* 13.83).—A group of islands in the North Pacific Ocean, annexed to the United States on Aug. 12 1898, and now represented in the American Congress by a delegate elected biennially. In 1925 the population, including military and naval personnel of 17,094, was 323,645 (an increase, exclusive of such personnel, of 59·7% since 1910).

Race must not be confused with nationality. Birth in Hawaii, as well as elsewhere in the United States, makes one an American citizen. Of the above total, 202,165 were Americans and 121,480 (including Filipinos who are neither citizens nor aliens) were not. Immigration of Orientals in the earlier stages produced an abnormal ratio not only of aliens to citizens but of adults to children and males to females, but later there was a rapid tendency toward normality. Except among Americans and Filipinos, the increase in population was in 1925 mainly through births. Departures have latterly exceeded arrivals, and the departures have been largely of adult aliens. The birth-rate was 41·57 and the death-rate 12·74 per 1,000 in 1925. While there was a growing tendency toward intermarriage among all races, the extremists in preserving racial solidarity are the Koreans and Japanese. The most noticeable social feature in Hawaii is the comparative absence of those racial antagonisms and prejudices prevailing in Asia and Europe.

Immigration has been occasioned by the rapid growth of industries. Many Latin and Oriental unskilled labourers were assisted to reach the country but this is now impossible under the immigration laws. Many of these with their children under improved conditions become skilled labourers. Hence the constant need of replenishing the supply of unskilled labour. The last immigration assisted by the Government (1906–12) comprised 5,288 Spanish, 4,962 Portuguese and 2,056 Russians. Since then the only assisted immigration has been of Filipinos by the sugar producers. These increased from 2,318 in 1910 to 49,335 in 1925. Chinese immigration, restricted previously, has been prohibited since 1898. The Chinese decreased until 1910, but have since increased slowly. The Portuguese, Porto Ricans and Koreans are increasing slowly and the Spanish are decreasing. The Japanese departures have exceeded arrivals since the "Gentlemen's Agreement" of 1907. The native-born Japanese, being American citizens, present the most important problem for the future. They increased from 4,855 in 1900 to 70,860 in 1925. Experience tends to show that the Japanese as well as the Chinese vote will be intelligent and conservative. Notwithstanding the comparatively small percentage of Anglo-Saxon Americans, the atmosphere—political, social and commercial—is conspicuously American.

Industries and Commerce.—Due mainly to the enterprise of the Anglo-Saxon element, the application of scientific methods, favourable soil and climatic conditions, location at the cross-roads of the Pacific and the American protective tariff, Hawaii has enjoyed prosperity for half a century.

Although prices of the principal products were low in 1925 the gains since 1910 were marked. Exports increased from $47,029,631 to $105,599,818; imports from $26,152,435 to $81,802,547; taxable property from $150,268,467 to $360,832,895; bank deposits from $13,324,305 to $60,809,716. Trade was chiefly with the mainland of the United States—$104,095,273 of exports and $72,145,418 of imports in 1925. The exports comprised sugar, $71,468,150; fruits and nuts, chiefly canned pineapples, $27,943,493; coffee, $1,197,535; sugar machinery, $616,270; and smaller values of molasses, hides, tallow, wool, canned fish, bananas, rice, honey and other products. Imports from foreign countries are largely nitrates from Chile, bags from India, and food supplies from Japan.

The sugar crop has increased considerably in recent years, not by increase of acreage, but by scientific discoveries of better methods of cultivation, fertilisation and irrigation, and new varieties of cane. The most striking feature in Hawaiian industries is the extent to which science is applied—through such agencies as the sugar planters' and U.S. experiment stations, the University of Hawaii and the territorial Bureau of Agriculture and Forestry. The yield of sugar per acre is larger than in any other country; but the cost is greater and 18 months is required for a crop. In 1925 the crop was 776,000 short tons—an average of about 6½ tons per acre. A few fields yielded over 18 tons, and one plantation averaged over 12 tons throughout. Half the acreage is irrigated by means of conduits from mountain streams, storage reservoirs and pumping from artesian and surface wells. The crops from the irrigated lands, though more costly, are so much greater as to be more profitable in general than those from the unirrigated lands in the wetter districts. The industry is conducted by corporations owning the mills and raising the cane. The capital stock is widely distributed and bought and sold freely on the exchange. The labourers receive house, fuel, water and medical attendance free. Day labourers, few in number, receive a minimum of a dollar a day plus a turnout bonus of 10% if they work 23 or more days a month plus a profit-sharing bonus of 1 % for each of a cent by which the average price of sugar for the month excee 4½ cents. About 95 % of the labourers take work by contract, as th gives them greater remuneration and more independence. Much h been accomplished in improving the living conditions of the e ployees by replacing tenements with cottages and garden spac providing hospitals, entertainment halls and motion-pictur play-grounds, kindergartens, social-service workers, instruction industrial methods and creating an *esprit de corps* by various mea

The canned pineapple industry is entirely a growth of rece years. Its output in 1925 was 8,728,580 cases of two-pound ca One factory is the largest fruit cannery in the world. The cr has been increased materially by the use of mulching paper. This rolled out on the fields in long strips, through holes in which t plants are set out. It serves many purposes, such as preventing wee from growing, conserving moisture, etc. While Hawaii exports a imports a larger percentage of what it produces and consumes th most countries, there is nevertheless much subsistence farming, a several industries, such as the livestock and fishing industries, figu largely in local trade. Much attention has been given to the import tion and raising of thoroughbred stock. The principal food of t Hawaiians is *poi*, manufactured from the root of the *taro*. There a no mineral products except building stone, lime and salt. Althou Hawaii is essentially an agricultural country, the industries are su as require much manufacturing, not only directly, as in sugar, r and coffee mills and fruit and fish canneries, but also indirectly, in iron and fertiliser works and can factories of large size. Ma factures of other products, such as biscuits, macaroni, starch, sho clothing, boats, etc., are on a small scale. Strikes of serious ext have occurred only twice, in 1909 and 1920, and unionism has o tained little foothold. There is a compulsory Workman's Co pensation law.

Communications.—Commerce on the Pacific is growi rapidly owing to industrial development on both sides of t ocean and the construction of the Panama Canal. The Fe eral and territorial Govts. and private enterprises have d veloped shipping facilities in Hawaii, located as it is at the co mercial cross-roads provided facilities at lesser ports for int island traffic; and developed the principal port on each of t four large islands for trans-Pacific and inter-island traffic. the newer wharves are of concrete. At Honolulu there a electrical freight-handling apparatus, automatic coal-handl plants, oil storage tanks connected with the wharves by pipe l and floating dry-docks. From 1910–25 the number of deep- steamers, exclusive of naval vessels, army transports and co bunker vessels, increased from 545 to 1,037; while sailing vess decreased from 232 to 31, and the combined tonnage increas from 2,589,097 to 7,993,137 tons. Some of these vessels solely between Hawaii and ports of the United States, mai San Francisco, Los Angeles and Seattle, but in part Atla ports; others are trans-Pacific, making Hawaii a port of between San Francisco and the Orient, Canada and the Ant odes, the Orient and Mexico or South America, while oth are round-the-world steamers. A fleet of 13 steamers is enga exclusively in the inter-island trade. There are 350 m. of se railways on the four principal islands and over 600 m. of priv railways on the sugar plantations. Hundreds of miles of c crete and macadam roads have been constructed. Beside cable there are four powerful wireless plants for trans-Pac communication, and smaller stations for communication tween the islands and with ships at sea. The five larger isla are well covered with efficient telephone systems.

Administration.—A direct primary law has been in operat since 1913 and woman suffrage since 1920. Racial distribut of voters differs much from that of population, dependin the case of each race partly on eligibility to naturalisation a partly on the percentage born in the United States and length of time the race has been in Hawaii. Hawaiians and pa Hawaiians are citizens; adult immigrant Portuguese, Span and Porto Ricans have generally been ineligible for naturali tion because of illiteracy; and Chinese, Japanese and Koreans ineligible under the Federal laws. In 1924 the registered vot comprised 21,575 men and 13,164 women, as follows: Hawa and part-Hawaiian, 16,685; Latins, 5,203; other Caucasia 9,124; Chinese, 2,016; Japanese, 1,711. There are two m political parties, Republican and Democratic, with the for usually in the majority.

Finance.—The bonded debt of the territory on June 30 1925 was 7,990,000. This has been incurred since 1910 for public improve-ents. Much current revenue also is expended on public improve-ents. The only local-government indebtedness consists of $2,080,-o public improvement bonds of the city and county of Honolulu d $1,280,293 district improvement bonds, the latter payable solely the property benefited, but $6,776,872 of the territorial debt has en incurred for county improvements, for which the counties reim-rse the territory in interest and sinking funds. The total revenue the territory and counties for the year ending June 30 1925 was 7,756,070 of which $8,283,262 went to the territory and $9,425,390 the counties ($47,418 undistributed) as compared with $2,621,758 d $1,394,695 respectively in 1910. The Legislature has recently ovided for a territorial budget system, a pension system for ritorial employees, and a uniform accounting system for the unties.

Education.—The educational system of Hawaii ranks high efficiency. It includes all grades from kindergarten to uni-ersity as well as a normal school and schools for the physically efective and feeble-minded. There is much manual work and dustrial training. Medical inspection of pupils is regularly ade and treatment is furnished free or at moderate prices and tention is given to nutrition. The university, established in 07, has 1,096 students. It possesses an aquarium and marine ological laboratory, conducts extension work and performs portant services in industrial experimental and research work. he number of pupils in the schools increased from 25,537 in 10 to 64,916 in 1925, of whom 55,044 were in the public hools and 9,872 in private schools. The cost of the public hool system is about $5,000,000 a year. More than half e pupils are Japanese. In addition the Japanese maintain an tensive system of so-called language schools. In 1920–5 laws ere passed subjecting all foreign-language schools, including me Chinese and Korean, to the supervision of the Department Public Instruction, limiting the sessions to shorter periods stricted to after public school hours, requiring the teachers to ss satisfactory tests in the English language, American his-ry and institutions and ideals of democracy, and providing r textbooks of superior pedagogical value and more suitable subject matter for American pupils. In 1912 a territorial brary was opened in Honolulu, with numerous stations through-t the territory which it supplies through travelling libraries.

Charities.—Of all the departments of the territorial govern-ent none except that of education is of wider scope or expends ore out of current revenues than that of public health. Phy-cians are employed or subsidised so that all, however indigent remote from population centres, may have proper medical ttendance. The principal territorial institution under this epartment is the leper settlement on the island of Molokai, ith its auxiliary hospital in Honolulu. Formerly emphasis as laid on isolation, but since 1909 emphasis has been placed n treatment, with the result that the number of lepers has een greatly reduced. Much progress has been made through ientific research and experimentation in effecting cures. haritable and welfare institutions abound in Hawaii.

History.—Hawaii's recent growth in importance has been arked not only in the scientific development of industries and s the commercial cross-roads of the Pacific, but as a great urist resort, as the great western military and naval outpost f the United States, and as the friendly meeting-place of East nd West. The tourist business has come to rank third in xtent. In 1909 the chain of small islands extending 1,200 m. the northwest of the larger islands was created a bird reser-ation—the largest and most numerous bird colony in the world. n 1916 the active volcanoes of Kilauea and Mauna Loa and e extinct crater of Haleakala were created a national park. he capital city, Honolulu, has grown rapidly. The naval sta-on and military post in Oahu Island are the greatest belonging the United States. Honolulu has been the seat of numerous an-Pacific conferences to foster among Pacific peoples the spirit f inter-racial brotherhood and promote co-operation among em for their common welfare—scientific, educational, press, mmercial and food conferences in 1920–4 under the auspices f the Pan-Pacific Union, and the Institute of Pacific Relations, atterned after the Williamstown Institute in 1925 under independent auspices. These unofficial conferences as well as the official Washington Conference bear witness to the growing importance of the Pacific area in world affairs. In 1920 the centenary of the landing of the missionaries was celebrated. The governors since 1907 have been: W. F. Frear, 1907–13; L. E. Pinkham, 1913–8; C. J. McCarthy, 1918–21; W. R. Farrington, 1921–.

HAWTREY, SIR CHARLES HENRY (1858–1923), British actor (*see* 13.104), was knighted in 1922 and died in London July 30 1923.

HAYASHI, TADASU, COUNT (1850–1913), Japanese statesman (*see* 13.109), died at Tokyo July 10 1913.

HAYES, PATRICK JOSEPH (1867–   ), American Cardinal, was born in New York City Nov. 20 1867. Graduating from Manhattan College in 1888, he continued his studies at St. Joseph's Seminary at Troy, N.Y., and was there ordained priest in 1892. After a graduate course at the Catholic University of Washington, he became curate of St. Gabriel's parish in East 37th St., New York City. In 1903 Archbishop Farley of New York, who had been his parish priest, appointed him his secretary and chancellor. In the same year Cathedral College was opened, and he became its first president, an office which he held for 11 years. In 1914 he was consecrated titular bishop of Tagaste and bishop auxiliary of New York. In the following year he was made rector of St. Stephen's Church, and on Nov. 24 1917 was appointed Catholic chaplain bishop for the U.S. Army and Navy, in which capacity he travelled extensively, appointing chaplains to the various camps. He was made Archbishop of New York in 1919. Early in 1924 he was summoned to Rome by Pope Pius XI. and was made a cardinal at a consistory held on March 25, being assigned the Church of Santa Maria in Via as his titular church.

HAZLITT, WILLIAM CAREW (1834–1913), British bibliographer (*see* 13.120), died at Richmond, Surrey, Sept. 8 1913.

HEALTH: *see* PUBLIC HEALTH.

HEALTH, MINISTRY OF.—The English Ministry of Health was set up by statute in 1919. The Act had as its principal object the concentration of the health services of England under a single Minister responsible to Parliament. These services had grown up under many departments: The Local Government Board, the Insurance Commissioners, the Privy Council, the Home Office and the Board of Education. The Act established a Minister of Health for England and Wales with a parliamentary under-secretary. Wales was given a Board of Health separately constituted but responsible directly to the minister. A similar Act was passed in the same year setting up a Scottish Board of Health. This last is a separate organisation and its parliamentary chief is the Secretary for Scotland, who has a parliamentary under-secretary for health for Scotland. There are thus two separate national health administrations in Great Britain whose only link is the association of their parliamentary chiefs in the Cabinet.

Powers of the Ministry.—The main organisation in the new Ministry of Health was the transformed Local Government Board, and this explains many of the functions, remote from its title, which the Ministry still exercises, such as, for example, its power over the finance of local authorities. When the Ministry came into being (July 1 1919) it assumed from that date the whole of the powers and duties of the Local Government Board, and of the English and Welsh Insurance Commissioners, save for the powers of the latter over the Medical Research Council (then the Medical Research Committee). The powers of the Privy Council relating to midwives were immediately vested in the new Ministry. On Oct. 1 it took over, as provided by the Act, the powers of the Board of Education with respect to the health of mothers and young children, and of the Home Office in relation to infant life protection under the Children Act 1908. On Dec. 1 the Ministry further assumed responsibility for the duties of the Board of Education regarding the medical inspection and treatment of children and young persons. Arrangements had, however, to be made to enable certain of these latter duties to be carried out by the Board of Education on behalf of the Minister of Health.

In May 1920 the Ministry took over from the Home Office the administration of the Anatomy Acts and of certain powers and duties in relation to lunacy and mental deficiency. Many powers inherited from the Local Government Board have been similarly transferred to other departments, such as the Home Office, the Board of Education, the Electricity Commissioners and the Ministry of Transport. An example of this process may be seen in the Order in Council dated May 27 1921, transferring the powers of the Ministry over electoral registration and elections to the Home Office.

Activities of the Ministry.—The activities of the Ministry are classified in five main sub-divisions: (1) public health, (2) local administration and taxation, (3) housing and town-planning, (4) administration of the Poor Law and of the Old Age and Widows and Orphans, Pensions Acts, (5) national health insurance. Of these, housing is the greatest purely post-War development, and has under the 1919 (Addison) Act and the 1923 (Chamberlain) and 1924 (Wheatley) Acts expanded so greatly as to form almost a Ministry in itself. Important matters relating to health services and administration are still under other departments. Of these the Privy Council holds perhaps the greatest share, though the Home Office has duties in relation to the inspection of factories and workshops, etc., of much importance to national health. The Medical Research Council, as stated above, was not transferred to the Ministry with the other branches of the Health Insurance Commissions, but passed under the Privy Council. (The Medical Research Council originated under the Insurance Act of 1911 as the Medical Research Committee.) In addition the General Medical Council, the controlling body of the medical profession, is under the Privy Council and not the Ministry of Health.

The Scottish Board.—The Scottish Board of Health performs duties in Scotland almost identical with those of the Ministry of Health in England. It is derived similarly from the Scottish Local Government Board and the Scottish Insurance Commission. The only service with no English counterpart is that financed from the Highlands and Island Medical Services Fund (instituted by statute in 1913), which provides practically a State medical service in these areas and is subsidized directly from the Exchequer.

It will be seen that the Ministry of Health is in no sense a department corresponding, say, to the Ministries controlling any of the fighting services, with a unified authority and sole responsibility for one task and one task only, which in this case would be the safeguarding of the nation against disease and the increase of its physical efficiency. The fact that the health services are worked almost entirely through local authorities, themselves popularly elected, would make this in any case impossible. It is not yet certain, even, whether these "health" functions will ever form a major portion of the Minister of Health's task. So far, the housing problem, the supervision and overhauling of local government, and, from time to time, the solving of vexed questions in the national insurance schemes have thrown altogether into the background the direct purposes from which, presumably, the Ministry originally received its name. It is indeed more than doubtful whether the health problems of the nation, affected as they are so intimately by finance, by food supply and by distribution of population, can ever b satisfactorily separated from the other activities with whic they interlock.

BIBLIOGRAPHY.—Very full information on all the subjects referre to will be found in the annual *Reports* of the Ministry and of th Scottish Board of Health. Health questions in particular are ex haustively dealt with in the separately published *Annual Report* o the Chief Medical Officer "On the State of the Public Health." (W. E. EL.)

HEALTH INSURANCE: *see* INSURANCE, SOCIAL.

HEALY, TIMOTHY MICHAEL (1855–), was born a Bantry on May 17 1855, the son of Maurice Healy, clerk of th Bantry Union. His mother was the daughter of a schoolmaste in this little west Cork town. Three of her brothers, A. M. T. D. and Donal Sullivan, became Members of Parliament, as did three of her sons, Thomas, Maurice and Timothy Healy The eldest married his cousin, a daughter of T. D. Sullivan This group of closely related politicians was the nucleus of th "Bantry Band" which included also W. M. Murphy, M.P. founder of *The Irish Independent*. In the succeeding generation Kevin O'Higgins, Timothy Healy's nephew by marriage, be came vice-president of the Irish Free State when his uncle was made its first governor-general.

But the future governor-general inherited nothing but brain and a strong nationalist tradition. He began to earn his living at 13, and his early youth was spent as a shorthand clerk in a railway office at Newcastle-upon-Tyne. Here he became wel known in Irish political and literary societies. In 1878 he moved to London and began in his spare time to contribute to the New York *Nation*. In 1879 Parnell on his first mission to America found that he needed a secretary and wired for Mr. Healy, who was already known to him. In 1880, after Parnell had been elected chairman of the Irish party, a parliamentary vacancy occurred in Wexford City, and Mr. Healy was elected.

From the first he slapped the House of Commons in the face but he attended very closely to all its business. In 1881 Mr Gladstone's Land Bill began the revolution which gave the Catholic Irish ownership of the land instead of being mere cultivators under landlords. Mr. Gladstone said that with the exception of three Irish law officers only Mr. Healy understood it, and it is doubtful whether anybody but Mr. Healy understood the effect of the famous "Healy clause." Introduced as an amendment, this guaranteed that in future rent should not be chargeable on tenants' improvements. When the bill became an act, Mr. Healy, called to the bar in 1884, defended the tenants' interests in innumerable cases that arose in its application. In 1883 his audacious tongue secured him the distinction of being sent to gaol. Later in the year when a Liberal seat became vacant in County Monaghan he was selected to make the first Nationalist inroad on Ulster. He won. At the general election of 1885 with the extended franchise Monaghan became a safe seat. Mr. Healy attacked South Derry and won the constituency—by surprise tactics. In 1886, however, he was defeated, but was returned for North Longford.

His relations with Parnell now became less friendly, and he joined Biggar in opposing the candidature of Captain O'Shea for Galway City. The opposition was only overborne by Parnell's personal intervention. But in 1889, when the divorce petition against Parnell was undefended, Mr. Healy drafted the resolution carried by the party in favour of Parnell remaining at his post. "Parnell," he said, "is not a man, but an institution." Later, however, in face of Mr. Gladstone's declaration he changed his mind, and from the time the "split" began, no speeches were so envenomed as Mr. Healy's. He was twice publicly beaten; but no form of menace had ever the least effect on him. In 1892 he became member for North Louth, and, as a member of the anti-Parnellite party to which the large majority of Irish Nationalists belonged, he was specially supported by the Catholic clergy. His rivals for leadership, Mr. O'Brien and Mr. Dillon, had more following among the laity, but Mr. Healy was always a priests' man. At this time he devoted less time to politics, for his practice at the bar was increasing, and in 1899 he became Q.C.

On the reunion of parties in 1900 he joined Mr. O'Brien in
ging that Mr. Redmond, leader of the Parnellite minority,
ther than Mr. Dillon, leader of the anti-Parnellites, should be
osen as chairman of the united body. But a long indulgence
the savage spirit of faction which followed the Parnell "split"
d rendered Mr. Healy difficult to work with, and in 1902, on
e motion of Mr. William O'Brien, he was expelled from the
nited Irish League, though he retained the support of the
atholic hierarchy and of Mr. Murphy's influential newspaper.
1906 Mr. William O'Brien, having split away from Redmond's
ain body with a few followers, made a working alliance with
s former adversary and his brother Maurice, member for Cork
ity. In 1910, when Mr. Healy was beaten in North Louth, Mr.
'Brien provided him with a constituency in north-east Cork.
Mr. Healy joined the English bar in 1903 and took silk in
10. He was unceasingly employed on English cases, more
pecially of a political character, and defended many of the
ffragettes. In Parliament no speaker was more able to draw a
owded house, and his wit and eloquence were specially popular
ith the Tories, because he said more biting things of the Na-
onalist party than Englishmen could invent. With Mr. O'Brien
opposed the Budget of 1909 which led to the clash with the
ouse of Lords; and on the Home Rule measure of 1912, while
ving it general support, he furiously opposed partition.

In 1914 he was a vigorous supporter of Britain in the World
ar, but the course of events from 1916 onwards, culminating
the introduction of conscription, drove him finally to side
ith Sinn Fein, and in 1918 he resigned his seat to allow an
prisoned Sinn Feiner to be returned. Little was publicly
ard of him during the years of turmoil which followed until,
the close of 1922, the constitution of the Irish Free State
aving been made law by the Irish Parliament, and subsequently
the British, the office of governor-general had to be filled.
hen Mr. Healy's name was first mentioned for the post there
as general incredulity, but the appointment soon commended
self to Irishmen of all sections. The Free State Government,
eaking through the mouth of Mr. Healy's nephew, Mr. Kevin
'Higgins, defended the choice of "an old man of the people,"
hile others realised that Mr. Healy, though an extreme nation-
ist, had in many respects a most conservative mind. Those
ho feared the worst from a tongue and a temper which he had
ever before governed were surprised by the result; for during
is continuance in office as the representative of King George Mr.
ealy in no way added to the Government's difficulties, while
e did more perhaps than any other person to cultivate the good
ill of the Protestant minority. (S. G.)

HEARST, WILLIAM RANDOLPH (1863–), American
ewspaper proprietor, was born in San Francisco, Cal., April 29
863. He entered Harvard in 1882, but left after three years
ithout finishing his course. As the only child of George F.
earst, a mining man of great wealth, he had the use of ample
apital at the outset of his career. In 1886 he became proprietor
f *The San Francisco Examiner*, the first of a long chain of pa-
ers to come under his control. In 1895 he bought the New
ork *Journal* and in the following year founded *The Evening*
ournal, the morning paper being known after 1902 as *The*
ew York American. Other papers founded by him were *The*
hicago American (1900); *The Chicago Examiner* (1902); *The*
os Angeles Examiner (1902); *The Boston American* (1904);
nd *The Atlanta Georgian* (1906). He also purchased *The*
oston Advertiser (1917); *The Chicago Herald* (1918), thereafter
ombined with *The Examiner* as *The Herald and Examiner;*
he Washington Times (1919); and the Milwaukee *Wisconsin*
ews (1919). He was likewise proprietor of *The Cosmopolitan*
agazine; Good Housekeeping Magazine; Harper's Bazaar; Hearst's
agazine; Motor Magazine; and *Motor-Boating Magazine.*

Hearst's papers were sensational in form and contents and had
n enormous popular circulation. They upheld the cause of the
eople against the moneyed interests, but the charge was often
rought that they appealed to the baser passions. They were
merica's chief representatives of "yellow journalism" (*see*
9.569). In 1916 they were barred from circulation in Canada "because of garbled dispatches" concerning the World War. After America's entrance into the War they were frequently charged with disloyalty, and in many towns attempts were made to suppress them. From 1903 to 1907 Mr. Hearst was representative in Congress from New York, and in 1904 had support as presidential candidate at the National Democratic Convention. In 1905 he was Democratic candidate for mayor of New York on the Municipal Ownership ticket, and four years later on the Independence League ticket; in 1906 he was candidate for the governorship of New York on the Democratic and Independence League tickets, being defeated in every instance. He strongly opposed the League of Nations. He became head of the news syndicate known as the International News Service.

HEART, DISEASES OF THE (*see* 13.132).—The years from 1910 to 1925 have been a brilliant epoch in the history of cardiology. Most of the credit for this must be given to British workers, amongst whom the late Sir James Mackenzie and Sir Thomas Lewis have been pre-eminent. For a long time Mackenzie had been carrying out his memorable investigations on the venous pulse, using for this purpose a modification of Dudgeon's sphygmograph; but it was not until after his invention of the Mackenzie ink polygraph in 1908 that the investigation of cardiac arrhythmia by graphic records became at all general as a clinical routine. By means of this instrument, or better still by Lewis's modification of it, it is easy to obtain a prolonged simultaneous record of the arterial and venous pulses together with time marks of ⅕ of a second. The careful study of such records yields much valuable information.

Electrical Records.—Electrical records of the heart beat have given even more accurate results. A minute electrical current is generated when the heart, or any other muscle, contracts; and in 1887 Waller was able to record the electrical current generated by the human heart beats, using for this purpose the capillary electrometer. In 1903 Einthoven, of Leyden, invented his string galvanometer (*see* 11.430), an extremely sensitive instrument capable of detecting a current of less than $\frac{1}{60,000}$ millionth of an ampère; this has the advantage of being practically aperiodic and free from "lag," grave defects of galvanometers previously used. It consists essentially of a powerful electro-magnet, between the poles of which is stretched a very fine fibre, usually a filament of drawn quartz, silvered to facilitate conduction.

If a minute electrical current passes along this fibre the fibre moves across the magnetic field in one direction or the other according to the direction of the current through it. By putting the human heart in electrical connection with the fibre, either by means of contacts from the chest wall in front of the heart, or, more conveniently, by three electrodes in which the two hands and one foot are immersed, the fibre is found to oscillate with each heart beat. The movements of the fibre are magnified by a projection lantern and photographed on a moving plate; the source of light is interrupted rhythmically at a known rate (usually every 1/25 of a sec.), and thus is obtained a curve of the electrical variations associated with each heart beat together with appropriate time marks. On such a curve the variations due to auricular and ventricular contraction respectively can be very clearly differentiated, the wave representing auricular contraction being designated arbitrarily as "P," and that representing the commencement of ventricular contraction "R." The time interval between these two components of each normal heart beat can be measured very accurately.

Heart Block.—In health this time interval is between 0·18 to 0·20 sec.; if the junctional tissues between auricle and ventricle are injured, either by disease or by cardiac poisons, conduction between auricle and ventricle is delayed and the "P.R." interval may become 0·24 sec., or even more. This state of affairs is known as heart block, and in its early stages can be recognised only by means of graphic records. With more severe damage of the junctional tissues, higher grades of auriculo-ventricular block ensue; thus the ventricle may respond only to every alternate auricular beat, or to every third or fourth auricular beat; or, finally it may be impossible for any stimuli to reach ventricle from auricle, in which case there is complete dissociation between the upper and lower chambers of the heart, the former beating at their usual rate of 60–80 per min. while the ventricles take on a rhythm of their own, usually at a rate of about 35–40. This condition is known as complete heart block. The presence of these more serious grades of heart block can often be surmised on clinical grounds, but graphic records are essential for their certain recognition. Heart block is one of the rarer causes of irregular heart action.

Other Features.—There are other causes of cardiac arrhythmia, some of which are benign, others serious. Quite early in the century it was impossible to differentiate with certainty between the benign and the serious types. Now, thanks to the knowledge derived from graphic records, this differentiation can be made with confidence, and often without the necessity for taking polygraphic or electro-cardiographic tracings. For instance, previously " intermissions " of the pulse were always considered to be serious. Probably many an operation has been unnecessarily postponed or cancelled on account of what are known as " premature beats "; these are extra-contractions which arise, either in auricle or in ventricle, independently of the ordered sequence of normal beats, every one of which arises in the upper part of the right auricle (the sinu-auricular node) and spreads thence from auricle to ventricle. These premature beats are now easily recognised and, in itself, this type of arrhythmia is devoid of serious import; no surgeon would now think of postponing an operation merely because of the presence of this type of arrhythmia, which is almost invariably present from time to time in most elderly subjects.

Auricular Fibrillation.—But there is another common type of cardiac arrhythmia known as auricular fibrillation which is of much more serious prognostic significance. Here, as a result of serious pathological changes in the heart muscle, the auricles cease to contract rhythmically as a whole in a series of orderly beats; but the auricular musculature is in a constant state of incoordinate and futile twitchings; in consequence, the ventricles, instead of being stimulated from above rhythmically at the rate of about 70 per min., now are overwhelmed by a series of stimuli which pour down on them like an avalanche. They do their best to respond, and contract rapidly and irregularly at a rate of 120–180 per minute. This condition, sometimes known as " delirium cordis," is very constantly associated with cardiac failure, usually ending in dropsy, shortness of breath and eventually, if progressive, in death. It is a dangerous condition, but when recognised—and about its recognition there is now seldom any difficulty—it may be controlled by the administration of digitalis. This drug depresses the conductivity between auricle and ventricle, and consequently only the more powerful auricular stimuli reach the ventricle after its use; the ventricle now beats, still irregularly, but more slowly, and consequently, having time for a longer rest between each beat, more powerfully. The auricles may fibrillate in paroxysms lasting a few minutes, hours or days; but more commonly the condition is a permanent one. It brings about a very considerable degree of disability, but, if properly controlled by the use of digitalis and if the patient is content to live within his limits, it is often compatible with 10, 15 or even 20 years of very fair health.

The Circus Movement.—Lewis has recently demonstrated by means of the string galvanometer that in auricular fibrillation, as in its sister condition, auricular flutter, instead of each auricular beat arising, as described above, in the sinu-auricular node and radiating thence throughout the auricles, a " circus movement " takes place in the auricular muscle, often around the mouths of the great veins entering the right auricle. We have to conceive of a wave of contraction whirling around, usually in an irregular circle, and one whose disposition in space varies from beat to beat. From this contractile path are projected into the surrounding auricular muscle countless stimulating impulses, very much as sparks are thrown out from a catherine wheel, and, as a result, the whole of the auricular musculature is thrown into incessant, shimmering contractions. So soon as this explanation of auricular fibrillation was put forward and accepted, it was manifest that, if we could bridge the gap between the advancing crest and the retreating wake of the contractin wave in its "circus," the heart might revert to normal rhythm It has been found that quinine and its allied alkaloids, of whic quinidine is the one usually employed, have such an effect. I rather more than 50% of cases of auricular fibrillation it i possible to bring about a reversion to normal rhythm b the use of quinidine. Unfortunately the process is not devoid of risk, and there is a tendency for many of the cases t relapse into fibrillation when quinidine is withdrawn, so tha cases for quinidine therapy should be carefully selected and i administration should not be attempted by those inexperience in its use.

Paroxysmal Tachycardia.—This is yet another condition th recognition of which is often possible only with the aid of electrocardiographic records. Here the heart beats with great rapidit (rates of 150–200 per min.), but regularly. There is an abru transition from the normal and slow, to the abnormal and rapi rhythm; the attack may last for a few seconds, or for a few days and ends as abruptly as it began. Such attacks may be associated with great respiratory and mental distress, and may lea to cardiac failure. Their differentiation from a purely nervou form of rapid heart action may be impossible without an electrocardiogram taken during both normal and abnormal periods It is very important from the point of view of both outlook an treatment to be able to decide whether a case of palpitations is purely nervous phenomenon, or true paroxysmal tachycardia, more serious and intractable condition.

X-rays in Cardiology.—Of recent years X-rays have been use more and more in the investigation of cardiac disease. By thei help alone really accurate information can be obtained as t the size of the heart and aorta. Percussion of the chest wall and the location of the apex beat of the heart by the finger, ar all we have to rely on, apart from X-rays, in estimating the siz of the heart, and the information derived therefrom is vague an often misleading. By means of the X-rays the dimensions of th cardiac silhouette can be determined to a nicety, and much wor has been done, particularly by French physicians, in ascertainin the normal standards of measurement of this cardiac silhouett and in tabulating departures from such standards in variou pathological states.

Vital Capacity.—Much work has been done with regard to th vital capacity in health and disease. The vital capacity is th maximal amount of air which an individual is able to expire from the lungs after taking the deepest possible inspiration. As result of vast numbers of observations by many different investigators all over the world we now know what the vital capacit of any healthy individual of a given height and weight should be Disease of either heart or lungs may very materially diminish the vital capacity, and the figure obtained for an individual' vital capacity increases or diminishes according as the diseas in question advances or tends to recovery. This, therefore, is means of recording numerically a functional disability and it progress. This is a possibility the value of which is greater tha is at first apparent. Unfortunately, the statement of a patien that he is better or worse is not always a true index as to th progress of his disease; and even when his doctor thinks there i an improvement, sometimes the wish is father to the thought.

The trend of all this instrumental investigation of the heart' action has been to stress the importance of the heart's muscl in cardiac pathology and to minimise the effect of valvula lesions, to which so much attention was formerly paid. Possibl the pendulum has swung a little too far in this direction, wit the result that there has been a tendency to make light of, o even altogether to ignore, quite definite valvular lesions in th absence of any evidence of muscular defect. Such an attitud is deplorable, for it is doubtful if the heart's valves are ever diseased without, at the same time, some defect in the heart' musculature, and, in any case, it is manifest that a heart of whic one of the valves either leaks or is narrowed is not as efficient a organ as one whose valves are healthy. The essential point i that the physician should refrain from diagnosing valvular disease unless he is sure of his grounds. Many of the cardiac mur rs heard through the stethoscope are not necessarily indicac of valvular or of any other disease. The innocuous nature of se "exo-cardial," "cardio-respiratory," or "haemic" murrs, had long been known to the more experienced physicians, t it required the mass experiment of the World War to teach lesson to the rank and file of the profession.

Lessons of the War.—During the early stages of the War thouds of healthy men were refused for general service on the unds of such murmurs, and many thousands more were unnecarily invalided out of the army, often with pensions, by reason the discovery of such murmurs after enlistment. Another on of the War was that the condition known as soldier's rt is usually not associated with any disease of the heart itf. The rapid heart action which is the most striking feature of s condition, though it is, in fact, only one of many symptoms sent, is due to a general rather than to a local condition.

In Dec. 1925 Yandel Henderson, of Yale University, pubed some work which may well prove to be of the greatest portance in clinical medicine as well as in physiology. He has ceeded in perfecting a comparatively simple method of deterning in adult or child, healthy or sick, the output of the heart r beat. From this it is easy to calculate the actual work done the heart, and to recognise with certainty departures from normal standards of efficiency. Thus we now have, at last, imple method of ascertaining with accuracy whether a heart functioning normally or not, and of re-examining the patient m time to time, and observing whether a defect of cardiac ction previously discovered is stationary, improving or deterating.

However valuable may be the information derived from elec-cardiographic and X-ray examination, from analyses of pired and expired air, or of arterial and venous blood, and m many other modern methods of clinical investigation, no e of these ancillary diagnostic aids as yet surpasses or equals importance the old-fashioned method of medical history tak. Symptoms properly elucidated and interpreted, are to-day, previously, more important than physical signs and laboratory ts. An ache beneath the breastbone brought on by exertion d passing away with rest, is of more significance than an errant electro-cardiogram. It will be a bad day for clinical dicine when physicians devote their time entirely to laborary methods of investigation and neglect the less dramatic t equally vital elucidation of the patient's symptoms.

(M. A. C.*)

HEART AND LUNG, SURGERY OF (*see* 13.133).—Since 1910 w surgical work on the heart has been mainly devoted to three bjects.

I. SURGERY OF THE HEART

Removal of Foreign Bodies Retained in the Heart Wall.—The fety of the methods of surgical approach to the heart has been rther demonstrated. Surgeons in many countries have reoved war missiles from the wall of the heart and from the perirdium with a surprisingly small mortality. R. le Fort (*Bull. Mém. Acad. de Méd.*, vol. 80, p. 147, 1918) removed 11 foreign dies from nine patients, with one death. Roberts successfully moved a bullet from the posterior wall of the left ventricle, hich had been present for seven years and was causing cardiac sturbance. The approach by resection of one rib and traversing e pleura was excellent. He had also removed four fragments shell from the pericardium in four patients by the same route, th no mortality.

Operations for Stenosis of the Valvular Orifices of the Heart.—new field for surgery in the treatment of what has for long en a purely medical subject is being opened up by work which at the present moment largely experimental. The subject is ll in its infancy, but enough has been done to show that with rther experience certain selected cases of mitral stenosis, in hich the musculature of the heart has not been too much damed, may be submitted to operation with a fair prospect of provement. Duff S. Allen and E. A. Graham (*Jour. Amer. ed. Assoc.*, Sept. 23 1922 and *Arch. of Surg.*, Jan. 1924) have invented an instrument which they call a cardioscope. This is a tube, closed at one end by a lens, which is introduced into the heart through a small incision. When the lens is pressed against the heart wall so that no blood intervenes, the endocardium, illuminated by a small electric bulb, is clearly visible. In the wall of the tube is fitted a rod ending in a small knife, with which a stenosed valve may be incised under direct vision. In dogs, when the incision to introduce the cardioscope was made in the auricular appendix, all the dogs recovered. E. C. Cutler and S. A. L. Levine (*The Boston Med. and Surg. Jour.*, June 28 1923), believing that a mere incision in the stenosed ring will heal without relief of the stenosis, invented an instrument which punches out a piece of tissue.

They have used this successfully in the case of a girl, aged 12, suffering from mitral stenosis. She was alive 10 months later and was still improving. H. S. Souttar (*Brit. Med. Jour.*, Oct. 3 1925) reports a brilliant operation on a girl of 15 with mitral stenosis and regurgitation. He exposed the heart by a flap operation, and placed a light clamp on the base of the auricular appendix. After two guide sutures had been inserted, the appendix was incised and drawn over the finger like a glove, haemorrhage being thus obviated. The interior of the auricle was easily explored by the finger, no effect on the pulse being noted. The blood pressure instantly fell to zero as the passage of blood through the orifice was abolished. Souttar intended to divide the stenosed orifice with a knife passed along the finger, but as the stenosis was found to be of moderate degree with little thickening of the valve, he contented himself with stretching the orifice with the finger. The appendage was ligated at its base and the wound of the chest wall closed. The patient's condition was improved and she was well three months later, though still somewhat breathless on exertion.

Cervical Sympathectomy for Angina Pectoris.—The cause of this very distressing disease is not settled with certainty. But as changes in the cardiac muscle, coronary arteries and aorta are usually present it may be considered.

Jonnesco, of Bucharest, in 1916 first performed the removal of the left cervical sympathetic chain, including the upper and middle cervical ganglia and the first thoracic ganglion. The result, followed for four years, was complete relief from symptoms. T. Jonnesco operates under spinal anaesthesia (*La Presse Méd.*, April 26 1922). W. B. Coffey and P. K. Brown (*Arch. Int. Med.*, vol. 31, p. 200, 1923) report six cases with one death and great improvement in the other five, H. Lillienthal (*Arch. of Surg.*, vol. 10, p. 531, 1925) three cases. In one, the cervical sympathetic was removed on both sides. All were cured. H. H. Kerr (*Ann. of Surg.*, vol. 82, p. 354, 1925) reports five cases. He removes the superior cervical ganglion only, under local infiltration anaesthesia by novocain, and obtains the same results as the others by the more formidable operation performed by Jonnesco.

II. SURGERY OF THE LUNG

Since the World War the surgery of the lung has made great strides, and in all countries is engaging the attention of active workers. While differential pressure anaesthesia of some kind is still advisable, the introduction of intra-tracheal insufflation has enabled the elaborate and costly pressure chambers to be dispensed with. For many types of operation ordinary inhalation anaesthesia, especially by nitrous oxide and oxygen, suffices. Local infiltration anaesthesia, combined with nerve blocking by novocain or some similar drug, is largely used, and for some operations is essential. It is being combined with light analgesia by nitrous oxide and oxygen, or even ether by some surgeons in the case of nervous patients, for whom deep general anaesthesia is inadvisable (*see* ANAESTHETICS).

Surgical Treatment of Pulmonary Tuberculosis.—Direct operations on the tuberculous lung, either by drainage of tuberculous cavities or the resection of one or more lobes of the lung, have been abandoned by the majority of thoracic surgeons. The great advance in latter years has been in devising methods of collapsing the affected lung either temporarily or permanently.

Principles of Collapse Therapy.—In all other parts of the body it is found that rest of the affected part is beneficial, but in the case of the lung the respiratory movements, exaggerated by coughing, continue unless the lung is compressed. By collapse, stasis in the lymphatic vessels occurs, preventing spread of tubercle bacilli to other parts of the lung and diminishing the entrance of toxins into the general circulation with consequent improvement of the general resistance of the body. Congestion of the collapsed lung with blood appears to occur, favouring the formation of fibrous tissue and healing of the lesions. Mechanically, the effect is to allow the retraction of the new formed fibrous tissue and to collapse cavities and dilated bronchi. This prevents the retention of secretions, which often become secondarily infected with other organisms, and allows the walls of the cavities to come in contact and so to heal. This retraction occurs normally to a limited extent by the pulling up of the diaphragm, the pulling over of the mediastinum, and the assumption of the expiratory position by the ribs, but falls far short of that necessary for complete obliteration of the cavities.

Methods of Producing Collapse.—Artificial pneumothorax was first proposed by James Carson, of Liverpool, in 1821, but was introduced into practice by Forlanini, of Pavia, in 1882 (*Gazz. d. Osp.*, 1882). It is now extensively practised by physicians all over the world. By the introduction of air, oxygen or nitrogen through a hollow needle into the pleural cavity the lung may be more completely collapsed than by any other method. As this method is simple and satisfactory it is the method of choice, and other operations are only undertaken when this is impossible, through the presence of adhesions binding the two layers of the pleura together (*see* PNEUMOTHORAX).

Division of Adhesions.—Where the adhesions are few and bandlike, so that a partial collapse only can be obtained, it is necessary to divide them. The operation of thoracotomy and division of the bands by direct vision is unnecessarily severe. Jacobaeus, of Stockholm, in 1913 devised an instrument similar to a cystoscope, which he calls a thoracoscope. After the induction of a pneumothorax this is introduced under novocain anaesthesia through a canula. Through a smaller canula a galvanocautery is introduced. Thus the adhesions may be burnt through under the vision of the operator without opening the chest cavity (H. C. Jacobaeus, *Proc. Roy. Soc. Med.*, 1922–3, vol. 16, p. 45). By using the cautery at a red heat only, haemorrhage is avoided. The adhesions often pull out a cone of lung substance in which may be a prolongation of a lung cavity, so that it is important to burn the adhesions through as near the chest wall as possible.

Paralysis of the Diaphragm.—Stuertz first proposed this operation by division of the phrenic nerve in the neck, which was independently devised by Sauerbruch. The result of depriving the diaphragm on one side of its motor innervation is that it rises in the thorax as much as 2½ to three in., thus allowing the lower lobe partially to collapse and putting it at rest. The operation is easily done in a few minutes under local anaesthesia by novocain, the nerve being found running obliquely across the scalenus anticus muscle in the neck. At first the nerve was simply divided, but it was found that accessory fibres joined it below the point of section in 20–30% of individuals. W. Felix's operation of " Exairesis " (*Deutsch. Ztsch. f. Chir.*, No. 171, p. 283, 1922) has gained favour. In this modification the lower end of the divided nerve is seized in forceps and gradually drawn out of the thorax. Sometimes the whole length of the nerve as far as the diaphragm is successfully extracted, but in any case the collaterals which join it in its upper part are also severed so that the paralysis is complete. The operation is used where basal adhesions are preventing full collapse in pneumothorax, as an addition to thoracoplasty, in some cases of early tuberculosis of the lower lobe only and for the relief of pain in the region of the diaphragm on coughing.

Extrapleural Pneumolysis.—The operation consists in separating the parietal layer of the pleura from the chest wall over a limited area and filling the space thus formed with some material which is not absorbed, thereby compressing the lung beneath. A portion of one rib is resected and the posterior pe osteum and endothoracic fascia are carefully incised. The glov finger then separates the outer surface of the parietal pleura fr the inner surface of the endothoracic fascia. As the air whi enters the cavity thus formed is rapidly absorbed it is necessa to provide some filling. Tuffier, in 1910, first used fat obtain from omentum or a lipoma. This has become one of the favour methods, the fat being obtained from the patient's thigh (Tuffi *Bull. et mém. Soc. de Chir. de Paris*, vol. 49, 1249, 1923). If very careful aseptic technique is not followed the fat may extruded. Owing to the difficulty of obtaining enough fat, Ba in 1913, used a paraffin filling (H. Baer, *Münch. med. Woche schr.*, vol. 68, 1921). This is readily available but is heavy, an tends to be extruded later in many cases. E. W. Archibald, Montreal (*Am. Rev. of Tuberc.*, vol. 4, p. 828, 1921), has used pedicled muscle graft obtained by detaching the pectoral muscl

The operation is almost confined to apical lesions and is use either alone, or following thoracoplasty, in cases where the ape of the lung is incompletely collapsed. It may also be of servi where the apex alone is adherent and a satisfactory pneum thorax has collapsed the lower part of the lung.

Extrapleural Thoracoplasty.—Collapsing operations on th chest wall were suggested as long ago as 1888 (Quincke) an 1890 (Spengler). In 1907 Brauer and Friedreich removed larg portions of the ribs in their lateral portions. Wilms, in 19 removed portions both posteriorly and anteriorly. The moder operation of paravertebral thoracoplasty is due to Sauerbruc and the Scandinavians: Bull, of Osol; Saugman, of Veilefior Jacobaeus and Key, of Stockholm. The operation may be do in one, two or more stages and consists essentially in resecting portion of the first to the 10th or 11th ribs posteriorly through long incision posterior to the scapula and turning forwards alo the 10th rib. The muscles attached to the scapula are divide and the scapula is turned forwards. It is essential that the rib should be resected as far back as the tips of the transverse pro esses of the vertebrae. The length of rib removed varies fro ½ in. of the first rib to 7 or 8 in. of the middle and lower one The operation is a severe one, but the mortality, which was a first about 8% has been reduced by proper selection of cases t about 2% in the hands of experienced operators. Many opera tors still prefer a local anaesthesia by novocain, but the tendenc now, except in cases with profuse sputum, is to operate unde general anesthesia by nitrous oxide and oxygen preceded by a injection of morphine and hyoscine. The results of these opera tions have shown that in cases of unilateral or mainly unilate pulmonary tuberculosis which are not improving under sana torium treatment a new field of hope is opening out. F. Sau bruch (*Chir. der Brustorgane*, 1920), H. C. Jacobaeus and E. Ke (*Acta Chir. Scand.*, 1923); P. Bull (*Proc. Roy. Soc. Med.*, 19 vol. 17, p. 1); J. Alexander (*Surg. of Pulmon. Tub.*, 1925); Gravesen (*Surg. Treat. of Pulmon. and Pleur. Tub.*, 1925).

Bronchiectasis.—Three types of operation are used in th treatment of this distressing condition: (1) Drainage operatio (2) operations to collapse the lungs, (3) radical excision of th affected part of the lung. (1) Drainage operations are palliati only and aim either at drainage of abscess cavities or, by makin a permanent bronchial fistula, at reducing the amount of sp tum. (2) All the forms of collapsing operations which are in u for pulmonary tuberculosis have their place in the treatment bronchiectasis. They are phrenicotomy, pneumothorax, extr pleural pneumolysis and extrapleural thoracoplasty. The pri ciples involved are, firstly, that the spaces in which secretio collect and decompose are obliterated by the collapse of th lung, and secondly that the new formed fibrous tissue in its co traction no longer pulls open the walls of the bronchi soften by inflammation, but can now pull inward the mobilised wal of the thorax. (3) In certain types of bronchiectasis the resul of collapsing operations are not satisfactory, and in consequen amputation of the affected lobe or lobes of the lung has bee performed. This procedure has produced real cures but th mortality of the operation is high. The longest series of cas is that published by H. Lilienthal, of New York (*Arch. of Surg*

. 8, 1924), whose mortality is nearly 50%. Many of his iients were, however, desperately ill. Evarts A. Graham *rch. of Surg.*, vol. 10, p. 392, 1925) has practised pneumectomy the actual cautery, in one or several stages, on 20 patients. these, 50% were cured, 30% improved and 20% died.

ntrathoracic Tumours.—Innocent intrathoracic tumours are ng diagnosed with greater frequency owing to the increasing of X-rays. H. C. Jacobaeus and E. Key (*Acta. Chir. Scand.*, 53, p. 573, 1921) have successfully removed four fibromata the transpleural route. T. P. Dunhill (*Br. Jour. of Surg.*, 2) removed a fibroma by Gask's modified sternum splitting ration. J. E. H. Roberts (*Tr. Roy. Soc. Med.*, 1926) has noved four innocent tumours, two fibromas, an encapsuled lothelioma and a dermoid cyst, three by the transpleural te and one by sternum splitting.

Malignant Tumours of the Lung.—Radical operations for the noval of carcinomata of the lung are rarely possible owing to later stage at which patients come under observation. Sauerbruch (*Chir. der Brustorgane*) has operated in five cases: e, with a carcinoma of the lower lobe the size of a small fist, s alive five years later; another was alive after three years. uerbruch advises a two-stage operation or three-stage operan, ligature of the branch of the pulmonary artery to the ected lobe being done as a preliminary followed by thoralasty and resection of lung.

Palliative operations often give great relief from distressing nptoms and prolong life for many months; they are (1) inage of a secondary lung abscess or empyema, (2) drainage sterile abscess due to necrosis of growth, (3) exposure of the wth for the insertion of radium, (4) treatment by X-rays.

IEAT (*see* 13.135).—The summary of recent works, given ow, is arranged for convenience as far as possible in the order he earlier articles connected with heat in the 11th ed. of the 3., as enumerated in 13.157, and references to them are made ere necessary.

nternational Notation.—The symbolic notation here adopted ased on that recommended by the International Commission the Unification of Physico-Chemical Symbols at their meetat Brussels in 1913, as extended by a special Committee of Physical Society of London under the presidency of Sir J. J. omson. Fortunately their recommendations coincide in the in with the notation employed in the 11th ed. of the *E.B.*, t a few changes have been made for the sake of uniformity, indicated in the following list.

Alphabetic Index of Symbols.

$A = 1/J$, Reciprocal of mechanical equivalent of heat.
a, Numerical factor for reducing PV to heat units.
B, Constant of integration in expressions for E and H.
b, Co-volume in characteristic equation of gas.
C, Cooling-effect of Joule and Thomson (*see* 27.901).
c, Co-aggregation volume in gas-equation.
E, Intrinsic energy.
G, Gibbs' function, $T\Phi - H$.
H, Total heat of vapour, $E + aPV$.
h, Total heat of liquid.
J, Joule's equivalent.
K, k, Thermal Conductivity, and Diffusivity.
L, Latent heat.
M, Mass.
m, Molecular weight or mass-flow.
N, Number of atoms or molecules.
n, Index in formula for c.
P, Pressure generally.
p, Saturation-pressure.
Q, Quantity of heat energy.
R, Gas-constant in $PV = RT$.
S, Specific heat of vapour; s, of liquid.
T, Absolute temperature; t, from 0°C.
U, Velocity of motion.
V, Specific volume of vapour; v, of liquid.
W, Work.
X, Cross-section of pipe or nozzle.
Φ, Entropy of vapour; ϕ, of liquid.
β, Radiation constant in $\beta\nu/T$.
γ, Ratio of specific heats of gas.
Λ, Velocity of light, 3×10^{10} cms/sec.
λ, Wave-length; ν, frequency.
η, Viscosity of gas.

CALORIMETRY

Units of Heat.—One of the most fundamental points in the measurement of heat is the relation between the practical units corresponding to the various methods discussed in the earlier article (*see* 5.60), in which the most important experimental evidence then available was described and reviewed. Some of the conclusions reached have since been contested, but additional experimental evidence has been obtained which seems to confirm the views previously maintained.

The experiments of Rowland by the mechanical method, agreeing closely with those of Joule when reduced to the scale of the gas thermometer, showed that the gram-calorie at 20° C. (defined as the quantity of heat required to raise the temperature of 1 gram of water at 20° C. under atmospheric pressure by 1° C. on the scale of the hydrogen thermometer) was equivalent to 4·180 joules of mechanical energy. Those of Reynolds and Moorby between 0 and 100° C. gave the equivalent of the gram-calorie as 4·1832 joules for the mean of the whole range, showing that the mean calorie was nearly the same as the calorie at 20° C., in contradiction to the results of earlier experimentalists who had obtained much higher values for the mean calorie. The best of the previous results by the method of mixtures for the variation of the specific heat of water between 0° and 100° C. were those of Lüdin (*see* 5.64, fig. 6), which gave a somewhat improbable curve for the variation, indicating a value 4·206 joules for the equivalent of the mean calorie, if the calorie at 20° C. was equivalent to 4·180. Most of the older results for the mean calorie, *e.g.*, those of Dieterici (*Wied. Ann.*, 33, p. 417, 1888), giving 4·244 by an electrical method with an ice-calorimeter, were much higher than Lüdin's. On the other hand, the continuous electrical method (*see* 5.65), in which platinum thermometers were employed in place of mercury thermometers, while agreeing very closely with Rowland's results from 5° to 30° C., gave a much slower rate of increase than Lüdin's for the specific heat between 40° and 100° C., and a value 4·186 joules for the mean calorie, confirming Reynolds and Moorby.

The later experiments of Dieterici, by the method of the ice-calorimeter employing a 10 times smaller current with a coil of higher resistance in order to reduce the uncertain errors of the electrical measurement, gave an equivalent 4·192 joules for the mean calorie. He also redetermined the constant of the ice-calorimeter, using water at 100° C. sealed in thin bulbs of quartz-glass, and obtained a value 15·491 milligrams of mercury per mean calorie, appreciably higher than the value 15·44 previously employed. This has since been confirmed by E. Griffiths (*Proc. Phys. Soc.*, 26, p. 1, 1913) who found the value 15·486 for a mean calorie of 4·184 joules. Owing to the smallness of the quantities of heat available for measurement at low temperatures, the ice-calorimeter is unsuitable for investigating the variation of specific heat in the neighbourhood of the freezing-point, but the observations of Dieterici at temperatures above 100° C. by the same method gave a rate of increase of the specific heat of water slightly exceeding that found by Regnault, which could not be reconciled with Lüdin's curve showing a maximum of specific heat at 87° C.

Messrs. W. R. and W. E. Bousfield (*Phil. Trans.*, A, 211, pp. 199–251, 1911) succeeded in reproducing Lüdin's results with remarkable fidelity by a most ingenious method of electric heating with a vacuum-jacket calorimeter. The heating-coil consisted of a long spiral of small-bore glass tubing filled with mercury, the expansion of which in a capillary tube was made to indicate the actual temperature of the mercury at any time when traversed by the electric current. The observers were thus enabled to avoid the source of error due to the superheating of the conductor above the temperature of the calorimeter. The uncertainty of heat-loss by evaporation from the surface of the water was minimised by protecting the surface with a cover in the form of a metal box maintained as nearly as possible at the same temperature as the water during an experiment. The rise of temperature over predetermined ranges, 0°–13°, 13°–27°, etc., was observed with suitable mercury thermometers of limited scale, standardised at the National Physical Laboratory. The corresponding quantities of electrical energy supplied, when corrected for external heat-loss and for the thermal capacity of the calorimeter, gave the increase of total heat of water, or the mean specific heat over each range. By adding the increments of total heat for each range, the *variation* of the total heat h, or the small difference $h-t$, could be obtained at each of the points of observation, as in the following table:—

Temperature C.	13°	27°	40°	55°	73°	80°	100°
Bousfield	0·058	0·058	0·059	0·124	0·242	0·306	....
Lüdin	0·057	0·059	0·064	0·119	0·285	0·371	0·633
Formula (1)	0·070	0·072	0·054	0·038	0·046	0·062	0·159
Dieterici	0·010	0·011	0·013	0·031	0·090	0·128	0·303

Bousfield's observations did not extend beyond 80°, owing to the difficulty of excessive evaporation with an open calorimeter. According to his curves, the corresponding values of the specific heat appear to be approaching a maximum at 80° C., a little lower than that shown by Lüdin's curve. The value of the specific heat at 80° C., according to Lüdin's formula, is 1·0184 in terms of the specific heat at 20° C. taken as unity, and exceeds the value given by the continuous electric method by 1·55 %. This looks alarming at first sight, but the method of comparison in terms of the actual specific heat, though commonly adopted, is really unfair, because the quantity actually observed in Lüdin's method is the total heat, which shows a difference of only 0 31 calorie according to the above table at 80° C. Dieterici's observations at 100° C., where they were most reliable, differ by only 0·14 % from the continuous electrical method, and he does not claim an order of accuracy greater than 0·1 % for the ice-calorimeter.

Continuous Mixture Method.—Since the number of separate determinations of the specific heat of water at points between 50° and 100° C. by the continuous electric method was only 12, and since these were made under conditions of exceptional difficulty, and differed most widely from the values found by Lüdin and Bousfield, it was felt to be desirable to confirm the variation in this region by an entirely independent method of equal accuracy. The continuous mixture method (Bakerian Lecture, *Phil. Trans.*, A, 1912, vol. 212, pp. 1–32) was devised for this purpose, and consisted in passing a steady current of water, initially at 100° C., through an interchanger, in which it gave up a large part of its heat to a current of cold water initially at 25° C., emerging at a temperature in the neighbourhood of 70° C., without having actually mixed with the cold current. The same current was then cooled to an accurately regulated temperature in the neighbourhood of 25° C., and re-entered the interchanger as the cold current. The point of the method is that the circulation is continuous, so that the water equivalent of the interchanger is not required, and that the hot and cold currents are *the same*, so that the quantity of the current divides out of the equation (except in the small term representing the external heat-loss) and need not be determined with an accuracy greater than 1 %, since the external heat-loss can easily be reduced to a small fraction of 1 % of the heat-exchange between the currents. The actual temperatures t_1 and t_2 of the hot current on entering and leaving the interchanger, and those of the cold current, t_3 and t_4, were observed with platinum thermometers to 0·001° C. If s' is the mean specific heat of the hot current between t_1 and t_2, and s'' that of the cold current between t_3 and t_4, we have the equation

$$s'(t_1-t_2)=s''(t_4-t_3)+\mathrm{X}/\mathrm{M},$$

where X is the external heat-loss in gram-calories per second, and M the value of the water current in grams per second. The heat-loss was determined, as in the continuous electric method, by varying the flow M while keeping the temperatures the same. In a large number of trials it was found that the ratio of s' to s'' agreed with the value 1·0050 given by the continuous electric method, but disagreed materially with the value given by Lüdin's formula. It was concluded that the discrepancy from Lüdin's formula was probably to be attributed to the unavoidable errors of his method, due to losses by evaporation at temperatures above 50°, and to the uncertainties of zero-point and stem-exposure which cannot be eliminated in the employment of mercury thermometers.

Formulae for the Specific Heat of Water.—It is usual to employ an empirical formula of the type, $s=1+at+bt^2+ct^3+$etc., which is familiar and convenient for the application of the method of least squares to the results of observation. The formulae most often quoted for water are those of Lüdin and Dieterici, which are as follows in terms of the calorie at 20° C.:—

$$\begin{array}{ll} \text{Dieterici,} & s=1{\cdot}0013-0{\cdot}0104(t/100)+0{\cdot}0208(t/100)^2 \\ \text{Lüdin,} & s=1-\underset{\pm 0\cdot 00025}{0{\cdot}07668}(t/100)+\underset{\pm 0\cdot 040}{0{\cdot}196}(t/100)^2-\underset{\pm 0\cdot 030}{0{\cdot}116}(t/100)^3 \end{array}$$

The probable errors of the coefficients, as given by Lüdin, are shown in the line below his formula. The formula of Dieterici represents his observations satisfactorily from 50° to 300° C., but does not apply to the variation near the freezing point, which cannot be represented satisfactorily by this type of formula without an additional term. The formula of Lüdin is fairly accurate between 0° and 25°, but appears to give results about 1 % too high between 60° and 90° C. It is also inconvenient in practice, because the coefficients are large and of opposite signs, giving the small variation required as a difference between relatively large terms. In the preliminary reduction of the results of the continuous electric meth
(*B. A. Rep.*, 1899) it appeared that a formula of this type wo
be unsuitable, and the observations were accordingly represen
by three simple formulae for different ranges of temperature betw
0° and 200° C., as given in the previous article (*see* 5.66). Th
have since been combined into a single equivalent formula, wh
is more convenient for several purposes:—

$$s=0.98536+0{\cdot}504/(t+20)+0{\cdot}0084(t/100)+0{\cdot}009(t/100)^2$$

The value of the constant is adjusted to make $s=1$ when $t=2$
The other terms are small and positive, and can be calculated w
sufficient accuracy for all possible purposes by means of a 10-
slide rule. This formula agrees very closely with the table p
viously given, but represents a later and more accurate reducti
It is of no theoretical significance, and cannot safely be extrapola
much above 100°C., but still agrees very closely with Regnaul
observations at 160° C. Above 100° C. it is better to use the therm
dynamical formula (*see* 27.903) suggested by McF. Gray, wh
agrees very closely with experiment from 40° to 100° C., but does n
represent the increase of specific heat with fall of temperature n
the freezing point. Gray's formula was re-defined by Callendar
representing the change of total heat of water under saturation pr
sure, and then agrees very closely with the observations of Dieter
at high temperatures, when corrected to give the change of to
heat in place of the intrinsic energy. It has a simple theoreti
foundation, and greatly simplifies the thermodynamical relati
between liquid and vapour. There is good reason to believe (Calle
dar, *Properties of Steam*, pp. 160, 196) that it continues to h
satisfactorily right up to the critical point, where the specific h
becomes infinite.

By experiments on the supercooled liquid, Prof. H. T. Barnes h
shown that the increase of specific heat with fall of temperature c
tinues to follow the same curve above and below the freezing poi
By very accurate experiments on mercury, using the continuo
electric method, he has shown that a diminution of the specific h
with rise of temperature occurs as in the case of water, but persis
up to a minimum at 140° C. It appears probable that a simil
phenomenon would be found for all liquids at low vapour pressur
but it is masked in the case of volatile liquids by the opposite eff
of the vapour-molecules, as represented by the thermodynami
formula. The diminution of the specific heat of water was attribu
by H. A. Rowland to the presence of a small proportion of soli
molecules in the liquid near the freezing point. The rapid incre
of the specific heat of a solid as the fusing-point is approached m
similarly be attributed to the presence of a small but rapidly increa
ing proportion of liquid-molecules in the solid. The proporti
required in either case, to explain the diminution of hardness a
rigidity of the solid, or the anomalous expansion of water near
freezing point, is small, but cannot be calculated with certainty
account of our imperfect knowledge of molecular forces and dim
sions. Such a theory would be difficult to verify in any case
experiment for the liquid and solid molecules.

Specific Heat of Gases and Vapours.—The continuous elect
method was first applied in the case of steam (*see* 27.901) and ga
results near 100° corroborating Regnault's value at higher temper
tures. The same method was applied to air and CO_2 by W. F.
Swann (*Phil. Trans.*, A, 1910, vol. 210, p. 199), who found resu
from 2 to 5 % higher than those of Regnault. Swann's formula h
since been verified by Holborn and Jakob (*Zeit. Ver. Deut. Ing.*,
p. 1429, 1914) and it is now generally recognised that this meth
is the most accurate for the determination of the specific heat
any fluid at constant pressure. Swann's values for air at 20° a
100° C. were closely consistent with those of Joly at constant volu
(*see* 5.67), and gave a ratio of specific heats very nearly equal
1·40, as required by the kinetic theory for a diatomic gas. Th
also showed a very small increase with temperature at the rate
only one-half of 1 % for 100° C. His values for CO_2 verified wi
improved accuracy the rapid increase with temperature foun
by Regnault and Wiedemann for this gas, which amounted to 12
for 100°. This increase of specific heat was not accounted for on th
kinetic theory, which required that all the degrees of freedom
a gas molecule should be equally excited, and should contrib
constant terms to the specific heat. The apparent discrepancy wa
explained (*B. A. Rep.*, 1908, p. 340) by supposing that a natu
frequency of the gas-molecule would be excited by radiation
direct proportion to the intensity of the corresponding frequency
each temperature. It was shown that a natural frequency havi
a wave-length of the order of 15 microns would be competent
produce the observed effect in the case of CO_2, contributing, wh
fully excited, a term R to the specific heat. An attempt was acco
ingly made to investigate the relation between the variation of th
specific heat of gases and the absorption and emission bands
their infra-red spectra. Some qualitative agreement was foun
but it was very difficult to make quantitative measurements of th
kind required, or to frame a consistent theory. For instance, the
is a strong band at 4·4–4·5 microns both in the emission and a
sorption spectra of steam. This band corresponds to the ma
mum ordinate of the wave-length spectrum of full radiation at
temperature T=647° C., the critical point of water, and appea
to be closely related to other properties of steam. There is no doub

t the properties of any substance are intimately related to the
ural frequencies of the molecules, but the form of the relation
not be predicted with certainty; and the quantitative measure-
its are not yet sufficiently exact to distinguish between many
sible hypotheses.

'he experiments of A. Eucken (*Sitz. Akad., Berlin*, 33.1, p. 141,
2) on the specific heat of hydrogen at low temperatures were
y instructive in this connection. The gas was electrically heated
various temperatures in a thin steel vessel under considerable
ssure at constant volume. The specific heat was found to dimin-
from nearly 5R/2 at ordinary temperatures to nearly 3R/2 at
60°, after which it remained practically constant down to T=35°.
experiments were undoubtedly of considerable difficulty, but
re seems no reason to doubt their substantial accuracy.

cken's results have recently been confirmed with remarkable precision by
Brinkworth (*Proc. Roy. Soc.* (A) 207, p. 542, 1925) using an entirely independent
hod of experiment. He observed the cooling effect in adiabatic expansion with a
pensated platinum thermometer at various temperatures between 20° C. and
3° C., and deduced the corresponding values of the ratio of the specific
s at constant pressure and at constant volume. The actual specific heats at
temperature could be deduced with certainty from these observations. This
hod is unaffected by the thermal capacity of the containing vessel, whereas in
ken's method the thermal capacity of the vessel must be known with consider-
accuracy. Brinkworth also showed that the heat-loss could be most satisfac-
y eliminated by using vessels of different sizes. Assuming that the variation
e specific heat was due to the response of some particular frequency of the
cule to the same frequency in natural radiation at each temperature, he states
Callendar's radiation formula fits the observations better than Planck's but
satisfactory agreement cannot be obtained by assuming a *single* frequency.
he's calculations do not seem to improve the agreement. The effect is probably
to an absorption band of $\lambda=25$–30μ in the infra-red.

Specific Heat of Solids at Low Temperatures.—The early experi-
its of Sir J. Dewar, Sir W. A. Tilden and others, had shown that
ds at low temperatures deviated from Dulong and Petit's law
he constancy of atomic heat in the same way as carbon, boron
silicon, at ordinary temperatures, but they failed to show the
extent of the deviation, or to indicate a probable explanation.
Einstein suggested (*Ann. Phys.*, 22, p. 180, 1907) that the atom
solid might be regarded as an electric resonator with three de-
es of freedom possessing a particular frequency, independent of
temperature, and capable of responding to the same frequency of
iation. Adopting Planck's theory and radiation formula, he
wed that the specific heat at constant volume should approach
limit $3R=5{\cdot}94$ calories per gram-atom at high temperatures,
required by Dulong and Petit's law, but that the variation at
temperatures should be given by the expression

$$s=3Rz^2e^z/(e^z-1)^2 = 3Rf(z) \qquad (2)$$

re $z=\beta\nu/T=C/\lambda T$, as in Planck's formula. The symbol ν de-
es the natural frequency of the atoms, and λ the correspond-
wave-length in cm. such that $\nu\lambda=\Lambda=3\times10^{10}$, the velocity
ght. The constant, $\beta\Lambda=C$, is Wien's constant of radiation.
king H. F. Weber's observations on the variation of the specific
t of the diamond, extending from T=222° to 1258°, Einstein
wed that they agreed qualitatively with this formula, if we
ld assume the diamond atoms to possess a single frequency cor-
ponding to the wave-length 11 microns. Taking the substances,
l, NaCl, KCl, $CaCO_3$ and SiO_2, for which the optical fre-
ncies in the infra-red were known, he showed that the frequen-
agreed in order of magnitude with those required by his formula,
that the observed wave-lengths were somewhat shorter than
se calculated from the specific heats. This could be attributed
he fact that most of the substances showed more than one fre-
ncy, and that the frequencies were not strictly monochromatic,
indicated by the width of the corresponding absorption bands.
any case there were other effects, such as work of expansion,
luded in the specific heats as ordinarily measured, and it might
doubted whether the optical frequencies corresponded exactly
h the thermal vibrations of the atoms.

An important series of experimental measurements, extending
vn to the temperature of liquid hydrogen, was made by W. Nernst,
A. Lindemann and their collaborators (*Sitz. Akad., Berlin*, p.
, 1911), on a number of metals and other solids, including
se for which the optical frequencies were known. They found,
already indicated, that Einstein's formula gave too low values
the specific heats at low temperatures, if the optical frequencies
e assumed in calculating the value of $f(z)$, and that much better
eement could be obtained by taking the mean of $f(z)$ for the
ical frequency, and a similar term, $f(z/2)$ at half the optical
quency:—

$$s=3R[f(z)+f(z/2)]/2 = 3Rf''(z) \qquad (3)$$

same function, $f''(z)$, of z was assumed to apply to other sub-
nces, such as the metals, but the appropriate values of z were
cted to fit the observations on the specific heats. Some sub-
nces, such as SiO_2 (in the forms of quartz and quartz-glass)
benzine, C_6H_6, which gave a different type of curve, were
resented by formulae with two or three different values of z,
h value of $f''(z)$ being multiplied by a fractional coefficient
resenting the proportion in which the corresponding molecule
supposed to be present. But such cases could not be regarded
verification of the theory, because it would obviously be possible
represent almost any type of variation in this way. Einstein
objected that even the simplest of these formulae, namely (3), was too empirical to be satisfactory from a theoretical standpoint; that a cubical crystal, such as KCl, or NaCl, could not have two different frequencies; and that there was no evidence in either case of an optical frequency with half the experimental value, since, according to Rubens, the crystals became again transparent before this frequency was reached, and had a value of the refractive index which was nearly normal. He also indicated two other objections to the "quantum" theory on which Planck's formula was based. (1) According to the quantum theory it did not follow, as required by the classical mechanics, that the oscillator with three degrees of freedom would have three times the energy of a linear oscillator. (2) It was very difficult to conceive the distribution of energy among the oscillators at low temperatures required by the theory. Thus for the diamond at T=73° only one molecule in 100 millions would possess a single quantum of energy, all the rest would be absolutely quiescent. It was physically impossible to conceive such a distribution of energy, which moreover would make the thermal conductivity of the diamond at such temperatures entirely negligible, whereas, according to Eucken, it was nearly as great as that of copper at ordinary temperatures. For these reasons Einstein preferred to rely mainly on the expression for the energy of an electric oscillator in equilibrium with radiation as deduced from Maxwell's equations, and to regard Planck's formula for the distribution of energy in full radiation simply as representing the results of experiment.

Debye's Theory of Specific Heat of Solids.—The theory now most commonly accepted is that of P. Debye (*Ann. Phys.*, 39, p. 789, 1912), who attributes the heat energy to mechanical or acoustic vibrations of the solid with all possible frequencies up to a certain limit ν_m. According to a theorem attributed to the late Lord Rayleigh (*Sound*, i., p. 129, 1877) the number of possible degrees of freedom of a system of N discontinuous mass-points will be 3N. According to another theorem by the same author (*Phil. Mag.*, 49, p. 539, 1900), the number of possible frequencies in a given volume of a *continuous* medium between the limits ν and $\nu+d\nu$ may be represented by $C'\nu^2d\nu$, where C' is a constant depending on the volume and the velocity of propagation. The total number of possible frequencies from 0 up to a limit ν_m is $C'\nu_m^3/3$. If we equate this to 3N, we find $C'=9N/\nu_m^3$. Adopting Planck's expression for the energy of an electric oscillator with one degree of freedom as applying to each possible frequency of the N atoms in a gram-atom, we obtain the energy $(RT/N)z/(e^z-1)$ for each frequency. Multiplying this by the number of frequencies between ν and $\nu+d\nu$, namely $(9N/\nu_m^3)\nu^2d\nu$, and integrating from 0 to ν_m, we obtain the energy of a gram-atom at T, from which the specific heat at constant volume is obtained by differentiation with regard to T. Unfortunately the integral cannot be expressed in finite terms and is too complicated to reproduce here. It is evident, however, that it will be a function of z_m, or $\beta\nu_m/T$, or T_m/T, where $T_m=\beta\nu_m$.

Thus the *form* of the curve representing the variation of the specific heat (which depends on a single parameter T_m or ν_m) is the same for all substances on Debye's theory, if the temperature scale is altered for each in proportion to ν_m. This point has been very carefully tested by E. H. Griffiths and E. Griffiths (*Phil. Trans.*, A, 214, pp. 319–357) for the metals Al, Ag, Cd, Cu, Fe, Na, Pb, Zn. Their results indicate qualitative agreement with the theory, but show characteristic differences, greatly exceeding the limit of experimental error, which may possibly be attributed to other effects not included in the simple theory. Thus the curve for Fe differs from that for Cu by nearly 20% between corresponding temperatures, which may be attributed to the magnetic properties of Fe. The curve for Na shows a rapid rise towards the melting point, reaching an excess of 25% above 3R, followed by a diminution of specific heat for the liquid, as in the case of water and mercury. Many simple compounds, such as NaCl, show curves of a very similar type to the metals, which has been used as an argument that the specific heat must be attributed entirely to the atoms, and that the free electrons supposed to exist in metals cannot make any appreciable contribution. Thus if there were two free electrons per atom, as required by some theories, the electrons alone would account for the whole specific heat according to the kinetic theory at ordinary temperatures; and it would be necessary to suppose that the number of free electrons diminished to zero at low temperatures, which would make it difficult to account for the enormous increase in electric conductivity of pure metals demonstrated by Kamerlingh Onnes in the neighbourhood of the absolute zero.

One of the commonest objections to Debye's theory is the arbitrary nature of the assumption of an abrupt limit of frequency ν_m. This assumption is made on account of its simplicity, but is highly improbable from a physical standpoint, though it might be expected to give results of the right order of magnitude. W. Sutherland (*Phil. Mag.*, 20, p. 657, 1910) had previously shown that the wave-length of the elastic vibrations of solids was of the same order of magnitude as the distance between the atoms for frequencies corresponding to the optical frequencies in the infra-red, so far as these were known. If the forces holding the atoms in place in a crystal lattice are electromagnetic, as commonly assumed, we should expect that the energy would be shared between matter and aether, and that the natural frequencies of the optical and mechanical vibrations would be the same. The wave-length and velocity of the natural frequency as measured outside the crystal would be reduced inside the crystal in the same proportion as the ratio of the velocity of light to that of an elastic vibration, or of the wave-length outside the crystal to the lattice constant, *i.e.*, in the case of rocksalt, NaCl, about in the ratio 2×10^5 to 1. Since the energy in the cube of the wave-length remains constant, the energy-density of the external radiation of the natural frequency would be increased in the cube of this ratio, and would be of the right order of magnitude to explain the specific heat of the solid on the usual theory of resonance as applied by Einstein. We have seen, however, that the assumption of Planck's radiation formula gives too low a value for the specific heat at low temperatures on Einstein's theory. If on the other hand we interpret Lord Rayleigh's formula, namely $C'Te^{-z}\nu^2d\nu$, as representing the *partial pressure* $pd\nu$ of radiation between the limits of frequency ν and $\nu+d\nu$, the latent heat of emission or absorption of radiation per unit volume between the same limits, according to Carnot's principle, is represented by the expression

$$T(dp/dT)=C'T\nu^2(1+z)e^{-z} \qquad (4)$$

and the total heat of a gram-atom of solid in equilibrium with radiation having this distribution of energy is given by

$$H=3RT(1+z)e^{-z} \qquad (5)$$

The specific heat as ordinarily measured, when the external pressure is small as compared with internal pressure, will be simply

$$s=3R(1+z+z^2)e^{-z} \qquad (6)$$

This expression, unlike that similarly deduced from Planck's formula, gives good agreement with the observed value of the specific heat in the case of rocksalt, when the optical frequency corresponding to 51 microns is assumed, at a temperature corresponding to the maximum of the frequency curve, where $z=2{\cdot}732$, $T=100°$, and $s=8{\cdot}67$ (doubled for a gram-molecule of NaCl). We should expect to get good agreement at this point, in spite of the fact that the actual vibrations in a solid cannot be strictly monochromatic (as Einstein pointed out) but extend for a distance of an octave or more on either side of the maximum, as indicated by the absorption spectrum. The effect of this is to reduce the steepness of the monochromatic curve, bringing it into good agreement with observation at high and low temperatures, without materially affecting the agreement at the mean point corresponding to the maximum of the frequency curve. If we assume the value $\lambda_m T=0{\cdot}290$ for the wave-length λ_m (corresponding to the maximum ordinate of the wave-length spectrum of full radiation at T), in deducing the appropriate value of Wien's constant βA in formula (4), the maximum ordinate comes out the same as in Planck's formula, provided that the same value of the Stefan-Boltzmann constant σ is assumed in the fourth power law σT^4 for the total radiation. The two curves also agree so closely throughout their whole extent that it would be very difficult to decide between them by experiments on radiation. We should therefore be justified, according to Einstein's reasoning, in applying formula (4) in the deduction of the specific heat of a solid, especially when we find that the result gives such good qualitative agreement with the optical frequencies.

An obvious objection to Debye's theory in the case of transparent substances, such as quartz and rocksalt, is that, if the atoms have all possible frequencies below a certain limit, they ought to be completely opaque in this region, and to become suddenly transparent when the limit ν_m is surpassed. Experiment shows, however, that, *e.g.*, quartz, which begins to be opaque at about four microns, and has optical frequencies corresponding to 9 and 21 microns approximately, and possibly one lower, becomes almost perfectly transparent below 100 microns. The variation of its specific heat is of an entirely different type to that given by Debye's theory but corresponds closely, according to formula (4), with its optical frequencies. Ice and benzol, which are also hexagonal, show a variation of specific heat similar to quartz, according to Sir J. Dewar. The corresponding optical frequencies have not yet been observed, but it appears that water must have some frequencies below 100 microns to account for its remarkable opacity to long wave-lengths, and the variation of its specific heat. We should naturally expect that the torsional vibrations of an elastic solid, which are of the same kind as those of light, would be excited by radiation, and would be intimately connected with the optical frequencies. It is quite possible, however, that the compressional vibrations, which are of a different type, and propagated with a different velocity (that of sound), would continue to exist at low temperatures without affecting the transparency. These acoustic vibrations, though not capable of being excited directly by radiation, would be necessarily excited by the impacts of the molecules of the surrounding gas, with a distribution of energy corresponding to the Maxwellian law, and might be expected to provide a term in the specific heat of a somewhat similar character to the Debye term for compressional waves at low temperatures. It is noteworthy that Nernst and Lindemann in their latest reductions have found it necessary to retain the original Einstein term $f(z)$ for transparent substances in their formula (3), but have replaced the hypothetical term $f(z/2)$ by a term of the Debye type. The appropriate frequencies are calculated in most cases by Lindemann's semi-empirical formula from the molecular weight m, the atomic volume V, and the temperature of fusion T_f, but with different values of the constants for the terms, as follows:—

$$\nu_\epsilon=2{\cdot}12\times10^{12}(T_f/m)^{\frac{1}{2}}V^{-\frac{1}{3}}$$
$$\nu_m=3{\cdot}08\times10^{12}(T_f/m)^{\frac{1}{2}}V^{-\frac{1}{3}}$$

of which the first gives the optical frequency of Einstein and second that of Debye. The cube root of the atomic volume is portional to the lattice constant, and the elastic constants of a s must be closely related to the temperature of fusion. Nernst Lindemann assign equal importance to the two terms, but we sho naturally expect from elastic theory, as given by Debye and o previous writers, that the numerical coefficients should have di ent values, and should be proportional to $1/u_1^2$ for the comp sional waves, where u_1 is the velocity of sound, and $2/u_2^2$ for the sional waves, where u_2 is the velocity of light *in the solid* for particular optical frequency considered. This may not fit so with Planck's radiation formula for the Einstein term, but app to give better agreement with experiment if formula (4) is sub tuted for Planck's. The appropriate frequencies cannot be ca lated from the elastic constants for a discontinuous medium w out introducing arbitrary hypotheses, which are unsatisfact because the effect of the hypothesis selected is most import at the point where the discontinuity commences and it is difficul avoid selecting an hypothesis to give the desired result. Ther the further difficulty that the values of the elastic constants somewhat uncertain and liable to vary with temperature and depend on the particular specimen tested, especially with metals.

Sir J. Dewar (*Proc. R. S.*, 1913, A, 89, pp. 158–169) has measu the mean specific heats of the elements between the boiling po of hydrogen and nitrogen by means of his liquid hydrogen calor eter. The results for the specific heats, when plotted against atomic weights, give a curve showing a most remarkable coi dence with the well-known curve of atomic volume as a peri function of the atomic weight. In other words, the specific hea nearly proportional to the atomic volume, or to the cube of lattice constant, for similar substances, at this low temperat corresponding to a mean about T=50°. The relation does not tend to be exact, though it is a fair approximation over the ra 20° to 80°, but it illustrates the point that the atomic volume is most important factor in determining the frequencies.

In the case of the metals, which are opaque to all frequen below a certain limit, we should expect the possible frequencies extend over a considerable range, and to be grouped about a m in a similar way to the velocities of gas molecules on the kin theory. But there are many possible alternatives to the somew arbitrary hypothesis of Debye. We might suppose, for insta that of N molecules in a gram-molecule, the number possessing frequencies between the limits ν and $\nu+d\nu$ was represented an expression of the type

$$(N/2)e^{-x}x^2dx$$

in which $x=\nu/\nu_0=\beta\nu/T_0=\theta z$, where z denotes $\beta\nu/T$, and $\theta=T$ Multiplying this by expression (6) divided by N for the specific h of a single molecule of frequency ν, at a temperature T, and in grating the product from 0 to ∞, we obtain for the specific heat gram-molecule

$$s=3R(\theta^3/(1+\theta)^3)(1+3/(1+\theta)+12/(1+\theta)^2)$$

This is much simpler than Debye's expression, but gives a v similar curve. The *mean* frequency, $\nu_m=3\nu_0$, is nearly the s as Debye's limiting frequency. More accurately, Debye's chara istic temperature corresponds to $2{\cdot}91T_0$, in place of $3T_0$, on acco of the difference in the values of the constant β, which are in ratio 4·9651/4·8284 in Planck's and Rayleigh's formulae for rad tion. If Debye's scale is multiplied by 2·91, his curve agrees closely with (9) from $\theta=0{\cdot}6$ to $\theta=1{\cdot}0$. Below $\theta=0{\cdot}6$, (9) agr better with the Nernst-Lindemann curve (3), except that (9) te to vary as T^3 at very low temperatures, instead of vanishing ex nentially. Above $\theta=1$, the curve (9) lies above Debye's by a qu tity corresponding to the difference of the specific heats at cons pressure and volume. This is to be expected, because (9) repres the rate of change of total heat, which is the same as that of in sic energy for all practical purposes under the condition of sm external pressure and negligible expansion. Thus in the case water under atmospheric pressure, the increase of total heat betw 0° and 100° C. is 100 cals. C., and exceeds that of intrinsic en between the same limits by only 0·001 cal. C., which is 100 ti smaller than the limit of accuracy of observation; whereas change of total heat *at constant volume* between the same limi the case of water exceeds that of intrinsic energy by 21 cals., appro mately; but the correction from constant volume to constant pr sure is very uncertain, even in the best known cases. It theref appears to be more logical to employ a formula giving the spe heat at constant pressure directly, in place of applying an un tain correction. It should be observed, however, that (9) assu the mean frequency ν_m to be independent of T, as in Deb formula, which may be a good approximation in many cases. cannot be exactly true if the molecule changes its state. Curve reaches $s=3R$ a little above $\theta=2$, attains a maximum 3·195R $\theta=4$, and falls again to 3R at $\theta=\infty$. The fall is of the er of magnitude to explain the diminution of specific heat in the e of water, mercury and sodium. The distribution postulated (8) appears to apply fairly to most of the metals, but it fails ably for many other substances. Such cases might be treated pirically by modifying the distribution, or assuming special juencies, but such hypotheses would be of little value unless their sical meaning could be interpreted with reference to other perties of the substances.

CONDUCTION OF HEAT

n 1910 the very attractive theories of P. Drude and H. A. rentz were still commonly maintained, and were continually ng applied to the explanation of electrical and thermal effects. ording to their views a metal contained a number of free trons moving in all directions with velocities corresponding hose of gas-molecules on the kinetic theory. Drude showed t this assumption led to an approximately correct value of ratio of the thermal to the electric conductivity in the case ure metals, and Lorentz showed that it accounted for the g wave radiation from hot bodies. There were numerous er applications of the theory which appeared to correspond remarkable manner with experimental facts, but there were serious difficulties which appeared to render the adoption uch a theory premature.

he fluid state of scientific opinion on the subject in 1911 is l illustrated by the views expressed about that time by J. H. ns. In the report of the Solvay Congress, 1911, *On the Theory Radiation and Quanta* (Gauthier Villars, Paris, 1912), assuming t there were two free electrons per atom of the metal, Jeans k the view that the specific heat of metals was entirely due to movement of free electrons and not at all to the movements he atoms, "a hypothesis which accords well with our knowle of the internal movements of solids." On the other hand, is report on the quantum theory (*Phys. Soc.*, London, 1914), dopted the theory of Debye (according to which the specific t was entirely due to the movements of the atoms) as prob "destined to be final," and concluded that the free elecs do not contribute sensibly to the specific heat.

ir J. J. Thomson, *Corpuscular Theory of Matter* (1907), had ady pointed out that the number of free electrons required xplain thermal and electric conductivity was too large to ncile with the facts of specific heat on the assumption that electrons possessed the same energy of agitation as gas moles at the same temperature, and had proposed an alternative ry (*loc. cit.*, p. 86) previously suggested in his *Applications of amics to Physics and Chemistry* (1888). According to this , the metallic atoms, owing to their close proximity in the l state, were capable, under the influence of an electric field, orming Grotthus chains, along which they could exchange trons. There were no free electrons in the sense contemed by Drude and Lorentz, with velocities depending on the perature and contributing to the specific heat, but the ther agitation of the atoms tended to break up the chains, hat their number and length varied with the electric field in manner required to explain the relation between electric and rmal conductivity and many other effects.

n a later paper (*Proc. Phys. Soc.*, 27, p. 527, 1915), the same ry was applied to explain the striking phenomena of superductivity discovered by Onnes, who found that at very low peratures, in perfectly pure metals, a current once started ht continue for days instead of stopping almost instantaney on the cessation of the exciting field. According to J. J. mson's theory, it would naturally follow that, below a certain t, the thermal agitation would be insufficient to break up chains when once they were formed, which would explain it is that the electric resistance of most pure metals tends anish (apart from impurities) at a temperature *above* the lute zero. A working hypothesis of this kind is very useful he experimentalist as affording a mental picture of the physi conditions, and may help to explain the remaining diffiies with regard to the specific heats.

nductivity of Gases.—Prof. Knudsen drew special attention *ay Report*, p. 133) to the data for the thermal conductivity of s, as being more scarce and discordant, owing to experimental difficulties, than determinations of other properties, and as requiring attentive examination for the elucidation of the law of action between molecules. The hot-wire method of T. Andrews (*Phil. Trans.*, 1840) offers special facilities for relative measurements, such as the comparison of conductivities of different gases, or of the same gas at different temperatures, and has frequently been applied with this object in recent years. It has also been improved by introducing the usual compensation for end-effects, and employing more accurate methods of electrical measurement. But it remains liable to the difficulties depending on the small dimensions of the wire, and the uncertainty of the corrections for convection and radiation. For these reasons the parallel plate method, adopted by E. O. Hercus and T. H. Laby (*Proc. R. S.*, A, 95, p. 190, 1918) for measuring the *absolute* conductivity of air, deserves special mention, owing to the great care with which the method was applied, and the complete elimination of convection effects. They also give a very complete reduction of previous results for different gases with the view of testing the value of the numerical coefficient f in the relation, $k=f\eta s$, between the conductivity k, the viscosity η, and the specific heat s at constant volume. According to the theoretical investigations of S. Chapman (*Phil. Trans.*, A, 211, p. 433, 1911) the value of the coefficient f should be 2·5 for a gas constituted of spherically symmetrical molecules, which agrees with Maxwell's theory based on the inverse fifth-power law of force, and also with experiment for monatomic molecules. Unfortunately the variation of viscosity with temperature does not satisfy the fifth-power law, which requires that the viscosity should be directly proportional to T. The conclusion is that monatomic gases may have spherically symmetrical molecules, but that the law of force is different. Theory gives no clear indication with regard to the appropriate value of f for other types of molecules. Experiment gives approximately a linear relation, $f=2{\cdot}816\gamma-2{\cdot}2$, between f and the ratio of the specific heats. This gives $f=7/4$ for diatomic gases, which show fair agreement with each other. The experimental values for polyatomic gases are much less certain.

THERMODYNAMICS

Since the general principles of thermodynamics have not undergone any material change for the last 50 years, it will readily be understood that such progress as there is to record relates chiefly to matters of expression or convention, and to the practical application of the principles to engineering problems. The evolution of the steam turbine and the internal combustion engine, along thermodynamical lines, has illustrated the importance of an exact and consistent theory of the conditions limiting the efficiency, and of an accurate experimental study of the properties of the working fluid in either case. Thus the improvement of the internal-combustion engine has depended greatly on the extension of the thermodynamical efficiency of the cycle by using higher compression-ratios, which has necessitated careful attention to the reduction of heat-losses, to the properties of various fuels in respect of detonation, and to the specific heats of the products of combustion at high temperatures.

The displacement of the reciprocating engine by the turbine for large power units has similarly depended on the possibility of improving the economy by utilising high vacua. The high speed of the turbine has directed special attention to the importance of losses due to friction and supersaturation, which depend on the rapidity of expansion. The turbine realises the ideal condition of steady flow with an exactitude unattainable by the reciprocating engine. This has made it worth while for engineers to adopt the thermodynamical definition of total heat first proposed by Callendar in the 10th ed. of the *E.B.*, in place of Regnault's definition, which had sufficed for many years, but continually gave rise to minor difficulties and complications when applied to the turbine. In the article cited, and as repeated in the 11th ed. (*see* 26.811), the total heat was defined as the thermodynamic function $E+PV$, and was denoted by the special symbol F in order to distinguish it from Regnault's total heat H, representing the quantity of heat added to the fluid under the condition of constant pressure equal to that of vaporisation. By general convention, the symbol H has now been defined as representing $E+PV$, a property of the substance depending only on the state, and the symbol Q has been allocated to any quantity of heat added under special conditions.

Equations of Steady Flow.—These depend on the law of conservation of mass, and on the law of conservation of energy, of which they afford some of the simplest possible illustrations. If a fluid is flowing steadily at a constant rate M (mass per second) through a circuit (pipe or nozzle) of variable cross-section X, at a point where the mean volume is V per unit mass, and the mean velocity U units of length per second, we have $MV=kUX$, where the constant k is unity in any consistent system of units, *e.g.*, if U, X and V are measured in ft., sq. ft. and cu. ft. respectively. It is common practice, however, to measure X in sq. in., which must be reduced to sq. ft. by putting $k=1/144$; and similarly for other arbitrary systems. If we consider any two points (1 and 2) of a circuit for which M and X are known, the relation $MV=kUX$ makes it possible to determine either U or V at each point if the other is known. A second relation is obtained from the conservation of energy. Suppose for example that the points 1 and 2 represent the admission and exhaust of a turbine. When the flow is steady, for each unit mass entering at 1, unit mass must leave at 2. Unit mass entering at 1 carries with it its intrinsic energy E_1 and its kinetic energy $U_1^2/2g$, in addition to which work P_1V_1 is done by the pressure P_1 in forcing the volume V_1 into the turbine. Reducing these to heat units by the appropriate numerical factors, a and J, we have finally for the total energy entering the turbine with each unit mass of fluid, $H_1+U_1^2/2Jg$, where H_1 is the initial value of the total heat, which is always tabulated in heat units per unit mass. Similarly the total energy carried out per unit mass at 2 is $H_2+U_2^2/2Jg$. Since the total quantity of energy existing in the turbine remains constant when the conditions are steady, the excess of the energy carried in over that carried out must be equal to the external work W/J done by the turbine together with the external heat-loss Q, both expressed in thermal units per unit mass passing through the turbine. We thus obtain the general equation representing the conservation of energy:—

$$\text{Heat-Drop, } H_1-H_2=W/J+Q+(U_2^2-U_1^2)/2Jg \qquad (10)$$

The reduction factors, a, J, g, can be omitted for absolute or C.G.S. units, but it is better to retain them explicitly, because the various quantities can seldom or never be measured in absolute units in practical work and the retention of the symbols saves much trouble and many mistakes.

In this equation, as applied to a turbine, the term W/J, representing the external work, is the most important on the right-hand side. The external heat-loss Q, and the leaving-loss, depending on the kinetic energy wasted in the exhaust, can be reduced to small corrections, which are readily applied. The external work is the equivalent of the corrected heat-drop, which can be calculated if the initial and final states of the steam are known. The equation takes exact account of any work wasted in internal friction, which does not appear explicitly in the equation because it affects both sides equally. The same equation can be applied to a reciprocating engine, or to any appliance admitting of steady flow.

Joule and Thomson (*Phil. Trans.*, 1854–62; *Proc. R. S.*, 1856) were the first to employ the function E+PV in their experiments on the flow through a porous plug or orifice. They discussed the various terms in the equation with great precision, but did not apply it to a steam engine, which was first done by Hirn and Rankine, though the equation is commonly attributed to Zeuner. In an ideal throttling experiment, such as that designed by Joule and Thomson, the equation shows that the total heat remains constant, $H_1=H_2$, provided that $U_1=U_2$ and that W and Q are negligible. The lines of constant total heat on the PT diagram can be determined by observing the initial and final values of P and T in a sufficient number of throttling experiments. It is then possible to deduce the actual values of H under any conditions by measuring the specific heat and latent heat at any one pressure, preferably atmospheric for most fluids.

In applying the equation to the discharge through an orifice Joule and Thomson showed that the kinetic energy generated was equivalent to the drop of E+PV, or H, which follows immediately from equation (10) if W and Q are negligible. In the usual case, starting from rest, U_1^2 is negligible as compared with U_2^2, so that U_2 is given by the simple relation

$$U_2=(2Jg)^{1/2}\,(H_1-H_2)^{1/2} \qquad (11)$$

For given conditions, V_2 is known in terms of H_2 and P_2, so that the discharge M/X per unit area can be deduced by applying the relation $M/X=kU/V$. Joule and Thomson showed that the discharge would reach a maximum in the case of air under adiabatic conditions when the final pressure after passing the orifice was 0·52 of the initial pressure, a result which had previously been deduced in a similar way by de St. Venant and Wantzel (*Comptes Rendus*, 1839) from Poisson's equation for the adiabatic, namely $PV^{\gamma}=\text{constant}$. They also showed that the velocity of the discharge under this condition was simply related to the velocity of sound in the air at the original temperature and pressure, but they failed to interpret the relation. Osborne Reynolds (*Phil. Mag.*, 1886, p. 194), using the same equations for a perfect gas, showed that the velocity at the throat or minimum area of the stream was *the same* as that of sound in the gas under the same conditions, so that, when this velocity was reached, no further lowering of pressure beyond the throat could possibly increase the discharge. The same result is easily shown to apply to any fluid, either liquid or gas, in the absence of friction. The condition that M is to be a maximum for a given value of X gives $d(M/X)=0$, whence $dU/dV=U/V$. Eliminating dU/dV by differentiating (11), we obtain, f isentropic flow (Φ const.)

$$U^2=aJgV(dH/dV)_{\phi}=aJgV^2(dP/dV)_{\phi} \qquad (1$$

which is the expression for the velocity of sound. This equation al gives the maximum discharge by substituting M/X for kU/V.

In steady-flow calorimetry the drop of H between given initi and final states can be deduced from equation (10) by observi the quantity of heat Q which must be abstracted, under con tions such that W and U^2 are negligible. The pressure is usual constant, but if there is a large drop of pressure between the initi and final states, as in Regnault's experiments on the total heat water, the difficulty is avoided, without changing H_1, by using throttle, which is precisely what Regnault did, though he w unable, owing to the defective state of thermodynamics at th time (1847), to appreciate the exact effect of this proceeding. T same method can be applied for measuring the total heat of ste in any state, including the latent heat. In all cases of steady fl the quantity measured is the change of total heat, which is the mo important property to determine for steam engines or refrigerati machines working on any modifications of the Rankine cycle. (the other hand the intrinsic energy E is the property required the constant volume cycle of the internal-combustion type.

A very simple and instructive illustration of the equation steady flow is that of the temperature gradient in a fluid und gravity. If a current of air is flowing steadily upwards at a mod ate speed, the external heat-loss Q and the change of kinetic ener are negligible, and the drop of total heat is equivalent to the wo done against gravity, giving $W/J=1$ calorie C. for each 1,400 ft. ascent. This would evidently be the same for any fluid wh ever. In the case of dry air the specific heat is nearly independ of the temperature and pressure, and the change of H is equal $S(t_1-t_2)$, where $S=0{\cdot}241$ is the specific heat at constant pressu The drop of temperature will therefore be $1/0{\cdot}241=4{\cdot}15$° C. in 1,4 ft.; or the temperature gradient, 0·296° C. per 100 ft. This result evidently quite independent of the initial temperature, or pressu or height, so long as we can afford to neglect the small variatio of S and g. In an ascending column of *damp* air, condensation se in with formation of cloud as soon as the temperature falls belo the dew point. The drop of H remains 1 calorie per 1,400 ft., b the temperature gradient is greatly reduced by the liberation of t latent heat of the vapour. On the other hand, in a descending cu rent, as in the ventilating shaft of a mine, the temperature increas with depth at the rate of nearly 3° C. per 1,000 ft., which, however, usually much less than the natural gradient of underground te perature (due to outflow of heat through the earth's crust), whi sometimes exceeds 10° C. in 1,000 ft. In this case there will be condensation, but the air may be cooled by evaporation, if the mi is kept wet to reduce dust, as is usually the case.

According to equation (10) the rate of increase of temperatu with depth, denoted by dt/dx, is equal to $1/JS$, and is uniform adiabatic flow if S is constant. The *pressure* gradient, dp/dx, gravitational units, is equal to the density $1/V$, or p/JRT, if R expressed like S in calories per 1°. Dividing by dt/dx, we ha $dp/dt=Sp/RT$, giving the adiabatic equation, which is commo assumed as the starting point to find the temperature gradie But the reverse order is more instructive as showing why the te perature gradient dt/dx is uniform.

Properties of Radiation.—The flow of heat by radiation from o body to another at a lower temperature is the commonest case steady flow. Owing to the high velocity of radiation and the abse of thermal capacity in the circuit, the steady state is established i small fraction of a second if the temperatures of source and si are constant. The quantity measured in a radiation experime is not the energy E of the radiation, as is frequently assumed, b the total heat E+PV, which is the same in the case of radiatio the latent heat of emission, namely $VT(dP/dT)$, for a volume according to Carnot's principle. This is universally admitted in t deduction of the fourth-power law (*see* 13.155), which follows f the fact that the pressure of full radiation is one third of the ene density, so that the latent heat of emission per unit volume is times the pressure. The quantity directly measured in experim on full radiation is the quantity of heat emitted per sq. cm. second from a black-body or perfect radiator at a temperatur and is denoted by σT^4, where σ is the Stefan-Boltzmann cons of full radiation. By the geometrical conditions of the problem, t quantity σT^4 is $\Lambda/4$ times the latent heat per unit volume, or times the energy-density in an isothermal enclosure at T, where is the velocity of light. The qualitative verification of the fou power law requires only a receiver capable of giving correct rela values of the radiation received, and is now generally accepte satisfactory; but the absolute measurement of the value of the c stant σ is a much more difficult problem, which has frequen been attacked in recent years without obtaining so high a deg of concordance as is desirable in so fundamental a research. value $5{\cdot}32\times10^{-5}$ ergs per sq. cm. per second, found by F. Ku baum in 1898 (*see* 13.155), was accepted for several years, tho it rested on a somewhat doubtful value of the absorption coeffic of the bolometer. Moreover, the assumption that the radi energy measured was equivalent to the electric energy required roduce the same rise of temperature in the bolometer, was rendered omewhat uncertain by conduction effects at the ends of the strips. similar bolometer, with the end-effects compensated, as employed the solar eclipse of 1905, gave the somewhat higher value $5{\cdot}60\times$ 0^{-5}. Kurlbaum (1912) gave the corrected result $5{\cdot}45\times10^{-5}$. F. 'aschen and W. Gerlach, by a modification of Ångström's method *Ann. Phys.*, 38, p. 41, 1912), found the value $5{\cdot}80\times10^{-5}$, which was onfirmed by G. A. Shakespear (*Proc. R. S.*, A, 86, p. 180, 1912), and y H. B. Keene (*Proc. R. S.*, A, 88, p. 49, 1913), who found $5{\cdot}67\times$ 0^{-5}, and $5{\cdot}89\times10^{-5}$, respectively. W. Coblentz (*U.S. Bur. St.*, 12, . 553, 1916), by a method similar to that of Paschen and Gerlach, ound the value $5{\cdot}72\times10^{-5}$, which is a fair mean of the previous esults. One of the most promising methods is that of the radio-alance (*Proc. Phys. Soc.*, 23, pp. 1–34, 1910), in which radiation eceived through a measured aperture is completely absorbed in a mall copper cup, and is compensated by the Peltier cooling-effect ue to a current through a thermojunction. Unfortunately, these xperiments were interrupted by the War, and the final reductions ave not yet been completed. There seems to be little doubt that urlbaum's original value was too low, but there are many pit-alls in such difficult experiments, and most of the methods adopted re liable to some objections.

It is generally admitted that the distribution of energy in the pectrum may be represented within the limits of experimental rror by Planck's formula (*see* 13.156), namely,

$$E d\lambda = C'\lambda^{-5}d\lambda/(e^{c'/\lambda T}-1) \tag{13}$$

If this formula is integrated from 0 to ∞, and equated to σT^4, ssuming that it represents the distribution of energy in the spec-rum as observed experimentally, we find for the constant C', in erms of c' and σ, $C'=15\sigma(c'/\pi)^4$. The value of the distribution onstant c' is most readily deduced from the wave-length λ_m cor-esponding to the maximum ordinate of the energy curve at T, nce by Wien's law the product $\lambda_m T$ is the same for all tempera-ures. According to Planck's formula the maximum occurs at the oint $\lambda_m T=c'/4{\cdot}9651$. Planck took $\lambda_m T=0{\cdot}294$, and $\sigma=5{\cdot}30\times$ 0^{-5}, giving $C'=3{\cdot}735\times10^{-6}$, and $c'=1{\cdot}460$. But if $\lambda_m T=0{\cdot}289$, nd $\sigma=5{\cdot}72\times10^{-5}$, then $C'=3{\cdot}708\times10^{-6}$ and $c'=1{\cdot}435$, according to e latest values of $\lambda_m T$ and σ. A comparatively small error in c', hich is raised to the fourth power, suffices to neutralize the error σ. The weak point of the method is that the position of the max-num of an experimental curve cannot be fixed with any certainty hen the curve (as in this case) is far from symmetrical on either de of the maximum.

It is too commonly assumed that Planck's radiation formula, in ite of the weighty objections that have repeatedly been urged gainst it, is so firmly founded in theory and experiment, that no her formula is worth considering in comparison with it. It is so frequently asserted that no formula based on the "classical" echanics can possibly satisfy the required conditions. The argu-ent is somewhat as follows. The number of possible vibrations per nit volume of a continuous medium possessing the properties the ether, between the limits λ and $\lambda+d\lambda$ of wave-length, ould be represented by $8\pi\lambda^{-4}d\lambda$, according to Lord Rayleigh's ethod of calculation (*Phil. Mag.*, 49, p. 539, 1900), if the length path between each reflection is restricted to an integral multiple half a wave-length. If the different frequencies are regarded as parate inconvertible entities, like the molecules of different gases, etween which the energy must be equally divided, the whole of e energy would accumulate in the infinitely short waves, which is surd and contradicts experiment. It would be more natural, owever, from a physical standpoint to regard Lord Rayleigh's rmula

$$(8\pi RT/N)e^{-c''/\lambda T}\lambda^{-4}d\lambda \tag{14}$$

corresponding to the partition of energy among a number of *milar* molecules, according to Maxwell's law, which is universally lmitted in the kinetic theory of gases, as resulting from the steady ate produced by collisions. The steady distribution of energy of diation in equilibrium with matter arises in a similar manner from e Döppler effect, by which the energy of a group of waves is anged in the same proportion as the frequency at each encounter ith a moving obstacle. The frequency, or the reciprocal of the ave-length, corresponds to the energy, and occurs in much the me way in Rayleigh's formula, as the square of the velocity, or e kinetic energy, in Maxwell's law. On this view, Lord Rayleigh's rmula evidently represents the distribution of pressure-energy etween the different wave-lengths about a mean value RT/N, which, cording to the law of equipartition, should be the same as the essure-energy of a single gas-molecule at the same temperature.

If we take Rayleigh's formula as representing the pressure dis-ibution in full radiation, the expression for the latent heat of sorption L as measured experimentally (corresponding to (4) ove, but expressed in terms of the wave-length λ in the normal ectrum) may be written

$$L d\lambda = C''(T+c''/\lambda)\lambda^{-4}e^{-c''/\lambda T}d\lambda \tag{15}$$

tegrating from 0 to ∞ we find $C''=\sigma c''^{3}/8$. The maximum of is curve occurs at the point where $c''/\lambda T=2+2\sqrt{2}$, whence $c''=$ $8284\lambda T$. The absolute value of the maximum ordinate comes out $0{\cdot}65603(\sigma T^4/\lambda_m)$. The value of the same ordinate, calculated in the same way for Planck's formula (13), but with $c'=4{\cdot}9651\lambda_m T$ comes out $0{\cdot}65755(\sigma T^4/\lambda_m)$. It is a curious and significant fact that the maxima should be so nearly the same when the same values of the experimental data are assumed for both curves. The total areas of the two curves are the same, and they agree so closely throughout their whole extent that it would be practically impossible to distinguish between them with certainty by experiments on the distribution of heat in the spectrum. The greatest difference amounts to about 1% of the maximum ordinate, and occurs near the point $\lambda=\lambda_m/2$ on the short wave-length side, where the curve is very steep. This difference becomes quite appreciable in the specific heats, when the curves are differentiated, and seems to lead to better agreement with experiment than Planck's formula as explained above.

The most serious difficulty from an experimental standpoint in applying Planck's formula, is that the latent heat of emission per unit volume is always tacitly assumed (following Planck) to be the same as the energy-density, without taking any account of the pressure, whereas the existence of the radiation pressure is universally admitted as the basis of the deduction of the fourth-power law. The work done by the pressure, if it exists, cannot consistently be neglected in experimental measurements of radiation in steady flow. This is one of the most fundamental points in practical thermodynamics, but had not up to 1921 received sufficient attention from the mathematicians who have worked so elaborately on the theory.

VAPORISATION

A good deal of attention has been devoted in recent years to the study of the properties of vapours employed in heat engines and refrigerating machines. The importance of the thermodynamical aspect of the problem has been widely recognized by engineers as the only sure guide to improvements in efficiency, and it has been realised that equations employed to represent the properties of the working fluid must be exactly consistent with the laws of thermodynamics, if it is desired to avoid discrepancies in the results of calculations by different methods. The principal properties of vapours were discussed from this point of view in the earlier article (*see* 27.897). The theory there given still holds good, but it will be of interest to discuss some of the evidence which has since accumulated on the experimental side. The case of steam, for which the experimental data are more accurate than for any other substance, will be taken, as being far the most important to engineers, and as illustrating the properties of vapours at moderate pressures. At high pressures, on the other hand, in the neighbourhood of the critical point, the data for steam are somewhat deficient, owing to the difficulty of the experiments, and the impracticability of using steam as a working fluid under these conditions. In the critical region the properties of carbonic acid have been most widely studied on account of its use for refrigeration.

Properties of Steam.—The equations for steam, first proposed by Callendar in the 10th ed. of the *E.B.* (1902), were founded on experimental measurements (1) of the specific heats, s and S, of water and steam by the continuous electric method, (2) of the Joule-Thomson cooling-effect C with a differential throttling calorimeter and (3) on the adiabatic index γ for dry steam with a very sensitive platinum thermometer. These experiments, taken in conjunction with the laws of thermodynamics, sufficed to determine all the required properties fairly accurately at moderate pressures.

The experiments on the specific heat of water extended from 0° to 100° C., and, when taken in conjunction with those of Regnault at higher temperatures, showed that the total heat h under saturation pressure could be represented, with sufficient accuracy for the purpose, by the thermodynamic formula

$$h = st + avT(dp/dT) = st + vL/(V_s - v) \tag{16}$$

in which the constant $s=0{\cdot}99666$ is chosen to make h at 100°C. = 100 cals. C., or 180 B.T.U. per lb. at 212° F., reckoned from 32° F. The symbol a is the factor for reducing any product of dimensions pv to heat units. When p is in lb. per sq. in. and v in cu. ft. per lb., the reciprocal $1/a$ (which it is most convenient to use with a slide rule) has the value 9·722 on the Centigrade scale, and 5·401 on the Fahrenheit scale of temperature. V_s and v are the volumes of the dry saturated vapour and the liquid respectively, and dp/dT is rate of increase of saturation pressure p with temperature. When taken in conjunction with Clapeyron's equation for the latent heat, formula (16) gives a very useful relation between the total heat H and the volume V for *wet* saturated steam in any state,

$$H - st = aVT(dp/dT) = pV/\Pi \tag{17}$$

The factor $\Pi = p/aT(dp/dT)$, which varies slowly and is independent of the wetness, has been tabulated, as affording the most expeditious and accurate method of calculating either H or V when the other is known. The relation between H and V when p is given is that most commonly required in practical work. The same formula leads to a simple expression for the entropy Φ,

$$\Phi = s \log_e (T/T_0) + aV(dp/dT) \qquad (18)$$

which applies to wet steam of volume V, and also to the liquid if v is substituted for V. T_0 represents the freezing point, 273·1° C. or 491·6° F.

Values ranging from 0·305 at 0° C. to 0·665 at 160° C. had been proposed by various writers in 1900 for the specific heat of steam, but the direct measurements by the continuous electric method at atmospheric pressure from 100° to 160° C. gave results but slightly exceeding those of Regnault over the range 124° to 224° C., and showed that the limiting value S_0 at zero pressure was probably nearly constant and equal to 0·477. This was confirmed by L. Holborn and H. Henning (*Ann. Phys.*, 18, p. 739, 1905) in a qualitative manner by comparison with air over the range 110° to 820° C.

The experiments on the cooling-effect C, when combined with those of the specific heat S, showed that the product SC was a function of the temperature only, and gave the simple expression for the total heat,

$$H = S_0T - SCP + B \qquad (19)$$

for dry steam at any pressure P. The values for dry *saturated* steam, given by putting the saturation pressure p in this expression, while differing materially from Regnault's formula, gave good agreement with the experiments (*see* 27.902) of Dieterici at 0° C., and of Griffiths at 30° and 40° C., when the constant B was deduced from Joly's observations at 100° C. with the aid of the experiments on the specific heat of water. This formula was closely confirmed by the observations of H. Henning (*Ann. Phys.*, 21, p. 849, 1906) on the latent heat between 30° and 100° C. His later observations (*Ann. Phys.*, 29, p. 441, 1909) also gave good agreement with the same curve at 180° C., but showed a discontinuity at 120° C., which may be attributed to inevitable experimental errors in such difficult work. At higher temperatures, up to 260° C., equation (19) received theoretical confirmation from the formula for the latent heat proposed by M. Thiesen, namely, $L = L_1(t_c - t)^{1/3}$, based on the vanishing of the latent heat at the critical temperature t_c. As first applied by Thiesen himself (*Ann. Phys.*, 9, p. 80, 1902) to the case of steam, with 365° C. for the critical temperature, this formula gave results which were much too low for the latent heat. It was shown, however, by Traube and Teichner (*Ann. Phys.*, 13, p. 620, 1904) that the true value of t_c was 374° C., which brought Thiesen's formula into agreement with (19) to less than 1 in 1,000 all the way from 0° to 260° C., when the constants were properly determined from the known values at 0°, 100°, 180° and 374°, giving the result

$$\log L = 1{\cdot}9638 + 0{\cdot}3151 \log (374 - t) \qquad (20)$$

in the logarithmic form as required for practical calculations. The importance of this formula arises from the fact that direct determinations of H_s (for dry saturated steam) become exceedingly difficult and uncertain at temperatures above 180° C., owing to errors from leakage and wetness, and that a formula of this type has been verified for many other substances in the critical region, so that it affords the best guide to the probable variation of H_s between 200° and 374° C.

The throttling experiments showed that there must be a considerable variation of S with pressure, corresponding to the variation of SC with temperature. But the experiments on the adiabatic expansion of dry steam showed that the index $n+1$ in the equation P/T^{n+1} = constant, was very nearly constant and equal to 13/3 over a wide range of P and T. Since $S_0/R = 13/3$, it followed that the total heat of dry steam must be expressible in the form

$$H = (13a/3)P(V - b) + abP + B \qquad (21)$$

giving the convenient expression for the volume of dry steam,

$$V = (3/13a)(H - B)/P + 10b/13 \qquad (22)$$

It also followed that the coaggregation volume $c = c_0(T_0/T)^n$ in the equation

$$V - b = RT/aP - c \qquad (23)$$

must vary with temperature according to the index $n = 10/3$, giving for the variation of S and C, in terms of c, the formulae

$$SC = a(n+1)c - ab \qquad (24)$$

$$S = S_0 + an(n+1)cP/T \qquad (25)$$

It was obvious that these could not apply accurately at high pressures in the critical region, but they afford ample accuracy for all purposes in the pressures required in steam-engine practice.

The Munich experiments (*Forsch. Ver. Deut. Ing.*, 21, 1905) by O. Knoblauch, R. Linde and K. Klebe, on the volume of steam, proved to be quite inconsistent with the well-known equation of Zeuner, then commonly accepted, but showed the most remarkable agreement up to 180° C. with formula (23) deduced from the throttling experiments.

The variation of S with pressure given by (25), as predicted by the experiments on C, was qualitatively confirmed by the experiments of O. Knoblauch and M. Jakob (*Forsch. Ver. Deut. Ing.*, 36, p. 109, 1906) extending to 8 atmospheres.

Knoblauch and his collaborators have since extended their observations on th specific heat up to 30 atm. (425 lb.), and have published Steam Tables (Oldenbourg, Munich, 1923) extrapolated to 60 atm. (850 lb.). These results are in very fair agreement with (19), (22) and (23), especially near the limit of 850 lb. at a moderate degree of superheat, but show a rapid fall of total heat on approaching saturation. (See also "World-Power," for May and June 1924, and June 1925. Callendar has since extended his observations with the differential throttling calorimeter to 1,000 lb. pressure, and finds (as explained in *Properties of Steam*, p. 83 that the assumption that the cooling-effect C is a function of the temperature only gives better agreement with experiment at high pressures near saturation than th Joule-Thomson equation (23), though both are in practical accord at moderat pressures or high superheats. There is always a difficulty in securing accurat observations of the total heat or specific heat of *saturated* steam owing to systematic errors of wetness, but results accurate to 1 in 1,000 may readily be obtaine at a moderate degree of superheat.

Adiabatic Heat-drop.—The change of total heat H in frictionles adiabatic expansion or compression is frequently of considerabl interest as representing the work done by or on the fluid in the idea case, when there is no internal friction, and when no heat is supplie or lost externally. If the laws of thermodynamics are summarise in the form

$$dQ = Td\Phi = dH - aVdP \qquad (26)$$

in which dQ represents heat supplied per unit mass by friction o otherwise, we observe that, in the case of isentropic flow, for whic $d\Phi = 0$, the change of H is equal to the integral of $aVdP$ along th adiabatic, which is readily obtained by substituting for V in term of H and P from (22) or (17), for any given initial state and final pressure. We may also obtain the general expression for Φ from thos for H and V by integrating $d\Phi = dH/T - (aV/T)dP$. These expressions may be put in various forms according to the purpose fo which they are required. One of the most useful for dry steam is

$$DH_\phi = (H' - H'')_\phi = (H' - B - abP')(1 - T''/T') + ab(P' - P'') \qquad (27$$

in which H′, P′, T′, and H″, P″, T″, represent the initial an final states. An exact expression for the adiabatic heat drop DH_ϕ in the case of wet saturated steam, is readily obtained in terms of H and T′, T″. But in practice it is usually more convenient to tabulate H and ϕ, and the Gibbs' function $G = T\phi - H$, which has th advantage of being a simple function of the temperature only, an independent of the wetness for a mixture of water and steam in any proportions. From the definition of G, if ϕ is constant at its initia value ϕ'', we obtain immediately the convenient expressions

$$DH\phi = (T' - T'')\Phi' - G' + G'' = H' - H_s'' + T''(\Phi_s'' - \Phi') \qquad (28$$

The first expression is general, and is readily applied if G′ and G are tabulated. The second is obtained by substituting for G′ an G″ in terms of H and ϕ, but is applicable only if the final state saturated, so that H_s'' and ϕ_s'' are the tabulated values for dr saturated steam.

Effects of Supersaturation.—For the general theory of the behaviour of a vapour when cooled below the saturation temperatu without condensation *see* 27.898–9. The state of supersaturatio is very common, in rapid expansion, and has proved to be of son practical importance, as affecting the discharge through a nozzl and the efficiency of a turbine. It appears that steam usually follows the dry adiabatic, $P/T^{13/3}$ = constant, for some distance belo the saturation point. The drop of temperature is about three time as rapid as along the wet adiabatic, and the volume is smaller tha that of saturated steam at the same P and H. The heat-drop, an the velocity generated, are also smaller, for a given pressure dro than in the case of steam which is assumed to remain in the equili rium state of saturation throughout the expansion. If the initia steam is dry saturated, it usually remains dry for some distanc beyond the throat of a nozzle, so that the discharge, as given i equation (12), is obtained from the dry adiabatic, by substitutin $(dP/dV)_\phi = 1{\cdot}3P/V$ at the throat, which leads to values about 5 larger than those given by the equations for wet steam. This confirmed by experiment, and is represented by the numeric formula for the discharge M/X_t in lb. per sec. per sq. in. of throa when P′ is in lb./sq. in. and V′ in cu. ft./lb. in the initial state,

$$M/X_t = 0{\cdot}3155(P'/V')^{\frac{1}{2}}, \quad P_t/P' = 0{\cdot}545 \qquad (29$$

in which the small quantity b is neglected as being usually beyon the limits of possible accuracy of measurement.

The defect of heat-drop on reaching the throat is about 5%. If th steam continued to follow the dry adiabatic to low pressures, t defect of heat-drop would often reach 20%, which would be ver serious. But soon after passing the throat, the coaggregated mol cules begin to act as condensation nuclei, according to Kelvi equation (*see* 27.898). When this limit is reached, the condensatio takes the form of a very thick fog of exceedingly fine particles, a is extremely rapid, owing to the enormous number of nuclei avai able, about 10^{22} per lb. of steam. If the expansion is relatively slo the steam is transformed into the saturated state, and remains near saturated for the rest of the expansion. But if the expansion very rapid, as in an expanding nozzle at a velocity of 3 or 4,000 ft./se the steam will remain near the supersaturation limit with a loss heatdrop amounting to nearly 8% at low pressures, involving a co responding loss of efficiency. According to Wilson's experiments low pressures (*see* 27.899), the supersaturation limit is reach when the pressure is about 8 times the normal saturation pressu corresponding to the actual temperature of the steam. The equiv lent wetness of the steam at this point, when transformed to t aturated state at the same P and H, would be about 3%. This ppears to be confirmed by turbine tests at these pressures, but Wilon's experiments do not afford any direct evidence with regard to he limit at which condensation starts at higher pressures. It appears n theoretical grounds that the pressure ratio corresponding to the upersaturation limit should not be so high as 8 at high pressures, hich would require an excessive increase in the drop of temperature nd in the equivalent wetness of the steam at high pressures.

There is some evidence that the equivalent wetness at the superaturation limit is the same, namely 3%, at high as at low presures. This would permit a very simple method of calculation, but iore experimental tests are required to decide the point. The effect initial superheat in improving the efficiency of a turbine cannot satisfactorily explained on the older theory that the steam is in ie equilibrium state of saturation throughout the expansion, but a necessary consequence of the phenomenon of supersaturation. he loss due to supersaturation may be entirely eliminated if the uperheat is sufficient to prevent supersaturation. In any case the ss will be greatly reduced by superheat, and the results of calcuition appear to indicate that the improvement of efficiency may e exactly accounted for in this way. This point has been very illy discussed by H. M. Martin, in "A New Theory of the Steam urbine" (*Engineering*, vol. 106, 1918); and also by H. L. Callendar, *roperties of Steam*, pp. 305–12.

Carslaw, *Fourier's Series and Integrals;* and . H. Jeans, *Dynamical Theory of Gases.* For experimental details it always necessary to refer to the original papers, but *Physical and hemical Constants* by G. W. C. Kaye and T. H. Laby (1921) gives a andy and up-to-date summary of numerical results. (H. L. C.)

HEATING AND VENTILATION (*see* 13.160 and 27.1008).—he close association between heating and ventilation, especially modern practice, makes it desirable to treat the two subjects ogether.

I. HEATING

When the temperature inside a building is maintained above hat out-of-doors, a sufficient quantity of heat must be continuusly supplied to replace that which passes by conduction hrough the walls and roof of the building and to warm the coniderable quantity of in-leaking air. The heating system has to roduce the proper amount of heat and to distribute it.

The earlier forms of heating apparatus, such as the stove and he fireplace, deliver their heat to the room principally by adiation. In general, heating by convection is to be preferred om a standpoint of comfort in severe climates, and for this eason and because of the dirt and labour necessitated by their are, the stove and the fireplace are being largely superseded, specially in North America, by the warm-air furnace or by team and hot-water systems. In Great Britain the fireplace is till an acceptable method of heating because of the relatively iild climate.

Warm Air Furnace.—The warm-air furnace system satisfies he requirement of a source of heating removed from living uarters, gives a fairly successful distribution of heat throughout he house and is very low in cost compared with steam and hotvater systems.

It consists of a firepot in which the fuel is burned and a more or ss extended flue for the gases of combustion, the whole being surounded by a sheet-metal casing through which a current of air asses, absorbing heat from the hot surfaces of the firebox and flue nd passing thence through metal ducts to the rooms above. Air supplied to the base of the furnace casing either from out-of-doors r, more economically, by a return duct from some central room of ie house. The fundamental difficulty with the warm-air furnace that the force producing the circulation of air through the system, eing due only to the difference in the densities of the heated air in ie pipes and the unheated air without, is necessarily very small and onsequently it is difficult to heat rooms remote from the furnace, articularly under adverse wind conditions.

Steam-Heating.—This system consists of a boiler in which the eam is generated, a number of so-called radiators located in the ooms to be heated, and a system of piping which conveys the steam the radiators and returns the water of condensation to the boiler.

The Vapour System.—The so-called vapour system is a steam ystem operating at a pressure of only a few ounces above atmosphere compared with a pressure of one to five pounds for the ordinary eam system. In the vapour system the steam enters the radiator rough a valve near the top and the displaced air and the water condensation are conveyed away by return piping, the air being nally discharged from the system through a vent near the boiler. To prevent the flow of steam from the radiator into the return piping, a trap is usually installed at the discharge end of each radiator.

For large buildings the vacuum steam system is used very extensively. The arrangement of the radiators and piping is nearly the same as in the vapour system, and a vacuum pump is connected with the return piping. This increases the differential pressure through the system and promotes the rapid flow of steam to the radiators and the complete removal of air.

Hot-water System.—In the hot-water system, which is widely used in Great Britain, water is heated in a central heater, flows through pipes to the radiators, where it delivers its heat, and thence back to the heater. Circulation is produced, in the simple gravity type system, by the difference in weight of the column of heated water in the supply pipe and the column of cooler water in the return pipe. Most large systems employ forced circulation, produced by a pump in the circuit, thus insuring positive flow and permitting the use of smaller pipes. The hot-water system, because of the thermal capacity of the water contained in it, gives a less fluctuating output of heat to the rooms, but is for the same reason less readily capable of responding when the outside temperature changes. The hot-water system, using forced circulation, is frequently employed in heating groups of buildings because the heat output can be readily controlled from a central point by adjusting the temperature of the water.

Steam is produced for a heating system by a boiler which usually has the furnace or firepot incorporated in it. Where electricity is used for heating—a procedure sometimes employed where coal is expensive and electric current cheap—the boiler is fitted with electric heating elements of the submerged resistance type. In recent years, due to the increasing cost and scarcity of anthracite coal, boilers have been developed which will burn bituminous coal successfully and without excessive smoke. (*See* BOILERS.) This is accomplished by the introduction of air at certain points in the furnace or by other means for burning the volatile matter before it is chilled by contact with the cold boiler surfaces.

Temperature Control.—Temperature control is frequently applied to schools, offices and public buildings in order to secure constant room temperatures. There are several systems in use which regulate the flow of steam to radiators and adjust the position of dampers, under the control of a thermo-stat. Compressed air or electricity are used to furnish the power required.

Central Heating.—In Great Britain, and in Europe generally, the term central heating usually refers to the heating of a building by means of a furnace instead of fireplaces. As understood in North America, however, the term refers to the supplying of heat to a number of separate buildings from a central plant. When portions of a city are thus heated the term district heating is often synonymously used.

Either steam or hot water may be used as the medium for conveying the heat from the central plant. The pipes are carried either in tunnels, permitting ready access to them, or are buried a few feet below the surface enclosed in some form of conduit to insulate the pipe against excessive loss of heat and to protect it. The conduit sometimes consists of a thick-walled wooden box or tube in which case the wood serves as the insulating material; or it is made of concrete or clay tile and a layer of magnesia or asbestos is applied to the pipe as an insulator.

There are extensive systems of this type distributing steam commercially for heating, cooking and to some extent for power in New York City, Detroit, Pittsburg, Rochester, St. Louis and elsewhere. The largest areas covered are about one sq. m. in extent. Business districts and good residential districts of high class are the desirable territory.

Frequently the exhaust steam from electrical generating plants is utilised and is distributed at a pressure of from 2 to 10 lb. above atmosphere; but in some cities steam direct from the boilers at pressures up to 100 lb. or more is used. The consumption of heat by the individual buildings is metred either by a steam meter in the supply pipe or by a meter which measures the water of condensation as it is drained from the heating system of the building. Losses of all kinds between the boiler outlet and the consumer's meter are, in the more efficient systems, from 15 to 20% of the steam sent out from the boilers. Hot water is used as the distributing medium in some cases, but is not regarded as commercially satisfactory, largely because of the lack of a suitable means of measuring the amount of heat used by each consumer.

II. VENTILATION

The modern conception of ventilation (*see* PUBLIC HEALTH) distinguishes between the internal and the external effects of the atmosphere upon the body. Those factors having an internal effect are chiefly the humidity of the air affecting the mucous membranes in the respiratory passages, the amount of dust and bacteria in the air and the nature and strength of odours. Externally, the temperature, humidity and motion of the air play perhaps an even more important part by controlling the rate of heat loss from the skin. It is only recently that this cooling power of the air in ventilation has been quantitatively studied. In 1913 Sheppard and E. V. Hill established by tests a comfort zone, which showed, for still air, the relation between temperature and humidity necessary for comfort. More recently Houghten, Yaglou and others, in an investigation sponsored by the American Society of Heating and Ventilating Engineers, the U.S. Bureau of Mines and the U.S. Public Health Service determined the complete relations between temperature, humidity and air motion as they affect bodily comfort.

An adequate system of ventilation must supply a sufficient quantity of air, properly heated and humidified, so that its cooling effect will be correct. Dust and bacteria must be reasonably absent, and odours not excessive. In the more elaborate systems of ventilation, such as are used in schools, theatres, auditoriums and other densely occupied buildings, the air used for ventilation is drawn by a centrifugal fan over steam coils, passed through an air washer for cleaning and humidification, and forced by the fan through a system of ducts to the various inlet points of the rooms to be ventilated. Air is withdrawn from each room, through properly located outlets, into an exhaust duct and discharged to the outside by the exhaust fan.

Arrangement of Ventilating System.—The air washer consists of a spray chamber, in which the air is humidified, followed by a series of baffles wet by sprays which remove most of the dust, and finally there are a number of dry baffles which serve to remove any entrained water. The ventilating system may be used for heating as well as for ventilation.

Artificial cooling is sometimes used in theatres by supplying refrigerated water to the air washer (*see* REFRIGERATION).

HEBREW LITERATURE (*see* 13.169).—Modern Hebrew literature, the beginnings of which go back to the 18th century, is universal in scope and secular in spirit, thus contrasting with the purely legal, ritualistic or homiletic works of earlier times. This literature took its rise in Italy (M. H. Luzzatto, 1707–47), whence it shifted to Germany, showing at first, notably through the influence of Moses Mendelssohn (1729–86), a rationalistic and cosmopolitan tendency.

Following a brief period of activity in Galicia dominated by Biblical criticism and historical scholarship (Krochmal, 1785–1840; Rapoport, 1790–1867), Hebrew literature assumed a new character in Russia and Lithuania, where the so-called Haskalah movement developed—a humanistic and humanitarian spirit which set itself against the traditional exclusiveness of the Jew. It found expression in the historical and scientific compendia of Kalman Schulman (1819–99), in the novel (Mapu, 1808–67) and in poetry (Lebensohn, 1828–52; J. L. Gordon, (1831–92). The novelist P. Smolenskin (1842–85) heralded a reaction, hastened by the pogroms against the Jews, towards a Jewish national policy, which culminated in Zionism. Since his day Hebrew literature has been largely dominated by the idea of a national revival. This idea has found its most complete expression in the essays of Asher Ginzberg (Ahad Ha'am) who has resisted the tendency to lay undue stress on the economic and political factors in Zionism and has insisted on the conception of Palestine as the cultural centre of the Hebrew race.

The individualistic and symbolic spirit in Hebrew literatur
has been greatly influenced by the modern mystic movemen
among the Jews known as Hassidism. In the sphere of fictio
this spirit found its foremost representative in Isaac Loe
Perez (1851–1915), whose stories are distinguished by artisti
beauty and tenderness. Humour is the dominant characteristi
of two other famous Hebrew story-writers—S. J. Abramowitsc
(known as "Mendele," 1835–1918) and S. Rabinowitz (know
as "Sholem Aleichem," 1859–1916). Judah Steinberg (1863
1908), author of many stories, excels in the delineation
character, and in him the individual finds more complete an
varied representation than elsewhere in Hebrew literatur
This fact, and the clearness and fluency of his style, give hi
high rank among Hebrew novelists. Another novelist of som
distinction is R. A. Brandes (1851–1902), who chose the struggl
for religious reform as the theme of his principal novels.

Poetry has made rapid strides in modern Hebrew literatur
There is a host of contemporary poets, the most representative
whom is Hayyim Nachman Byalik (1873–). With the ex
ception of Judah ha-Levi (fl. 12th century) he is perhaps th
leading Jewish national poet, inheriting the idealism and th
prophetic seriousness of his people. He is pre-eminently th
poet of Jewish woe. To Jewish national hopes and aspirations h
seldom gives expression in his verse. None of the Hebrew poet
has grasped and represented the spirit of the Ghetto and it
poetry with so much sympathy and so much tenderness
feeling as Byalik. The ideas of Ahad Ha'am and the influenc
of Gordon's style and form are traceable in his poems. Next t
Byalik and in strong contrast with him stands Dr. Saul Tsche
nichowski (1875–). He was the first to introduce int
Hebrew poetry an admiration for the Greek spirit and the sens
of complete enjoyment of life. His work is remarkable for it
easy gracefulness and its varied rythms and metrical form
Dr. Jacob Cahan (1880–) is an idealist, whose poems be
the stamp of a marked individuality. In the poems of Zalma
Schneor (1886–) there is at times a gentle pessimistic vei
and his verse is full of life and beauty; the rhythm has harmon
and tunefulness, the imagery is rich, varied and striking, an
the movement quick and bold. His prose, too, is marked by th
same qualities. Among a list of poets of less distinction may
mentioned, Jacob Steinberg, Jacob Fichman, Isaac Katzenelso
J. J. Koplewitz, David Schimonwitz, the brothers Simon a
Pesach Ginsburg, Hillel Bavli, Judah Karni, A. Schlonsky,
Zebi Greenburg, Avigdor Feuerstein, Benjamin N. Silkiner a
Simon Leo Halkin. Modern Hebrew poetry, like Hebrew poet
in general, has been strongest in lyric.

The various transformations of Jewish life brought about
the Zionist and other Jewish movements and the influence
foreign literatures had their effects upon the shaping of co
temporary Hebrew fiction, notably the short story and
novel. There has been created a Hebrew short story, artistic
technique and generally psychological in presentation, delinea
ing the individual in a variety of moods and situations; but
the same time marked by a minute, torturing self-analysis,
an impotence in the will of the heroes and by an outlook up
life that is gloomy and despondent. The creators of these stor
are followers of Micah Joseph Berdyczewski (1865–1921), w
in his view of life was influenced by the individualistic theories
Nietzsche. Among the most notable story-writers of this gro
are Isaiah Domosehvitzky (known as J. Bershadsky, 187
1908), Joseph Hayyim Brenner (1881–1921), Gershon Sch
mann, Uri Nisan Gnessin (1880–1913), Hirsch David Naumb
and Isaac Dob Berkowitz. The melancholy and morbid spi
which some of these writers have introduced into the Hebr
sketch and novel is almost entirely traceable to the influen
of the Russian and Scandinavian literatures of the last f
decades. A notable exception to this tendency is S. J. Agnon,
original symbolico-mystical writer of short stories and a mas
of Hebrew style. Other writers of fiction who are free from t
pessimistic strain are A. A. Kabak, Moses Smilansky, L.
Orloff, S. Ben-Zion Guttman, Eliezer Steinman, Asher Bara
and A. Reubeni.

The adaptation of the Hebrew language to the needs of modern life owes much to Eliezer Ben-Yehuda (1858–1923), one of the pioneers of the idea of a Jewish national renaissance, whose ten-volume Hebrew dictionary (*Thesaurus totius Heraitatis*) is a monument of a life's devotion to the revival of Hebrew. The talent of David Frischmann (1863–1922)extended over the domains of the feuilleton, the short story, poetry and criticism. Dr. Joseph Klausner (1874–   ), the editor of the leading Hebrew monthly *Hashiloah*, is active in many fields—criticism, history, scholarship and journalism. He possesses considerable erudition and historic insight. Hillel Zeitlin, a mystic, has made original contributions to various phases of modern Hebrew literature. The greatest Jewish journalist, writing for Jews in Hebrew and in many other languages, is Nahum Sokolow. Reuben Brainin is a fine stylist and an able ritic but his literary ideas and tastes are perhaps too much determined by outside influences. In Dr. Simon Bernfeld (1860–   ) Hebrew literature has a many-sided and very prolific writer with a gift for presenting the results of scholarly research n attractive literary form. Wolf Jawitz (1847–1924) was a historian and a philosopher of religious romanticism. David Neumark (1866–1924) made original contributions to the study of Jewish philosophy. Jacob Klatzkin, Fishel Lachower, S. B. Maximon, Dr. S. M. Melamed, Joel Blau, Osias Thon, Mordecai Ehrenpreis, S. I. Hurwitz and others have contributed much to he development of the essay in Hebrew literature.

Hebrew literature, including its vernacular is a primary factor esponsible for the rejuvenation of the national Jewish spirit and for the emancipation of Jewish life from external influences. Literary activity came to a virtual standstill as a result of the World War and its consequences, which bore with especial everity on eastern Europe, formerly the chief centre of Hebrew iterature. During the last few years there has been a revival in eastern Europe, and a certain development in America; but he centre of this activity has shifted to Palestine.

HEDIN, SVEN (1865–   ), Swedish explorer, was born in Stockholm Feb. 19 1865. He was educated at the högskola in Stockholm, and Uppsala University and later studied at Berlin and Halle. In 1885–6 he travelled through Persia and Mesopotamia, and in 1890 was attached to King Oscar's Embassy to the Shah of Persia. In the same year he visited Khurasan and Turkestan and reached Kashgar in 1891. He is best known through his ravels in Tibet, which placed him in the first rank of modern Asiatic explorers. Between 1893 and 1897 he travelled across the Asiatic continent from Orenburg by the Ural over the Pamirs and the plateau of Tibet to Peking. During two other expeditions, (1899–1902, 1906–8) he made valuable additions to the scientific knowledge of these tracts and explored specially he sources of the Sutlej and the Brahmaputra. In 1902 he became a Swedish noble, and in 1909 the Indian Government nvested him with the K.C.I.E. During the War he made requent visits to the Turkish front and in 1923 he travelled round he world, through the United States, Mongolia and Russia.

Sven Hedin's writings include: *Journey through Persia and Mesopotamia and the Caucassus* (1887); *Journey through Khorasan and Turkestan* (1892–3); *Through Asia* (1898); *Central Asia and Tibet* 1903); *Adventures in Tibet* (1904); *Scientific Results of a Journey in Central Asia 1899–1902*, 8 vol. HEDJAZ: *see* HEJAZ.

HEIDENSTAM, VERNER VON (1859–   ), Swedish writer, was born July 6 1859 in Olshammar. He lived for several years in the south of Europe, Egypt and the East. On his return home, he began his literary career with a collection of poems entitled *Vallfart och Vandringsaar* (Pilgrimage and Years of Wandering) (1888) based on oriental life, and which formed a protest against the naturalism then prevalent in Swedish literature. This led to the great literary renaissance of 1890 in Sweden. In 1889 he published *Endymion*, an oriental story, and in 1892 his great work, *Alienus*, a fanciful romance concerning a pilgrimage in search of beauty through various ages and countries. His other collection of *Poems* (1895) indicates the author's transition to national ideas. This national tendency attained its zenith in his great prose work, *Karolinerna* (The Carlists), translated into English in 1902, a collection of stories about the time of King Charles XII. Then followed *Den Hellige Birgittas Pilegrimsfaerd* (St. Bridget's Pilgrimage) in 1901, besides descriptions of Sweden in ancient times and in the Middle Ages in *Folkungaträdet*, 2 vol. (1905, 1920), and *Svenskarna og deres høvdinger* (Swedes and Their Chieftains), 2 vol. (1908, 1909). In 1915 Heidenstam published *Nya Dikter* (The New Poet), and in 1916 was awarded the Nobel Prize for literature. See F. Böök, *Sveriges moderna litteratur*, 2nd ed. (1921).

HEIJERMANS, HERMAN (1864–1924), Dutch writer (*see* 13.212). His later plays include *Schakels* (1904); *Allerzeilen* (1906); *De Groote Vlucht* (1908); *Ahasuerus* (1912) and *Eva Bonheur* (1919). He lived for a few years in Berlin, but returned to Holland in 1912 in order to manage a society of players, and devoted himself to that work. He died in 1924.

HEJAZ (*see* 13.217).—Under the Ottoman régime the Hejaz, extending from Maʿan and ʿAqaba in the north to Hali Point on the Red Sea coast in the south, formed a *Vilayat* with a *wali* resident at Mecca, controlling a garrison of about 7,000 troops. In 1904 Turkish control of the northern part of the Hejaz was strengthened by the completion of the Hejaz Railway down to Medina. In 1908 Husain ibn ʿAli was appointed to be Amir of Mecca, and soon set himself to thwart the Turkish Govt., particularly in the matter of the extension of the railway to the city of Mecca.

The War Period.—The proclamation of a *Jihad* by the Turks at the outset of the World War made Arabia a source of potential danger to the Allied cause. Effective control of the Hejaz would have enabled the Turks and their Allies to threaten the sea route to the East, and Great Britain sought to counter this danger by entering into negotiations with Sharif Husain. The latter, inspired by great personal ambition, was ripe for rebellion against the Turks, and, after a lengthy correspondence on the subject of the terms on which he should espouse the Allied cause, raised the standard of revolt on June 5 1916. Mecca and Jidda (the latter after bombardment by British ships) were soon wrested from the Turks, and Taif surrendered to the Sharifian forces in September.

The Sharifian armies were unable to make any impression on the strong Turkish defences at Medina, but at this time Col. T. E. Lawrence appeared upon the scene, and in concert with Husain's third son, Amir Faisal, organised a brilliant guerilla campaign against the Hejaz Railway and the Turkish positions further north. The ports of Yenbo', Wejh and ʿAqaba (1917) fell in rapid succession, and with the subsequent capture of Maʿan and Shaubak, the Hejaz reached the northern frontier which it kept till July 1925. Medina, successfully defended by Fakhri Pasha till the end of the War, only surrendered on the receipt of explicit orders from Constantinople in Jan. 1919. The Amir Faisal represented Husain, who had assumed the title of king in 1916, at the Peace Conference of 1919 at Paris, and the Hejaz was admitted as an original member of the League of Nations, but King Husain eventually refused to ratify the Peace Treaties. In March 1919 King Husain's relations with Ibn Saʿud became strained owing to a dispute over the oasis of Khurma, and in May his forces advanced to occupy the place. They were routed by the Wahhabis at Turaba, and later (1922) Khaibar and Taima were in turn occupied by Ibn Saʿud.

Meanwhile, in the summer of 1921, Lawrence visited Jidda on behalf of the British Govt. to negotiate a treaty with King Husain, but negotiations broke down owing to the latter's inability to accept the *de facto* position in Palestine. Negotiations were subsequently kept alive by Dr. Naji al Asil, Hashimite representative in London, but were finally abandoned on the outbreak of war between Nejd and Hejaz in Sept. 1924.

Post-War Events.—The Sharifian administration, mild enough during the War, became more and more autocratic and even tyrannical with the passage of time. King Husain alienated the sympathies of his own people, and went out of his way to court the enmity of his neighbours. By the terms of the Peace Treaties he undertook to maintain the annual pilgrimage under satisfactory conditions for all Moslems, but this part of his administration left much to be desired. There was much corruption in all government departments. Education was wholly neglected. Even the army was not maintained on an efficient basis. An Air Force was inaugurated in 1921, but was allowed to disintegrate owing to the King's parsimony—it was revived in the autumn of 1924 by his successor and reorganised in 1925. An effective scheme of wireless communication, with eight or nine well-equipped stations, was perhaps the brightest feature of King Husain's administration. The nucleus of a transport fleet (four ships) was also formed by him, and proved invaluable during the war with Nejd. A local coinage and stamp issue emanated from Mecca during these years, and a semi-official newspaper (*Al Qibla*) was started by the King for propaganda purposes.

Meanwhile the storm was approaching. King Husain refused until too late to send a representative to the Conference convened at Kuwait by the British Government. In Jan. 1924 he arrived in Transjordania on a visit to his son, ʿAbdullah, and, while there, he assumed the vacant title of *Khalifa* on the deposition of the Turkish Sultan-Khalifa by the Kemalist Govt. of Angora. He then hastened back to Mecca to issue invitations to the Moslem world to recognise his new status, but his overtures met with little success, and the Wahhabi Sultan realised that his ambitious enemy must be crushed at once.

Husain Abdicates.—In Sept. 1924 Ibn Saʿud launched his armies on the Hejaz. Taif fell without a show of resistance. Consternation reigned at Mecca, and King Husain, under pressure from the notables of Jidda, abdicated on Oct. 5 in favour of his eldest son, ʿAli, who was acclaimed as "King of the Hejaz only." King ʿAli evacuated Mecca and hastily recruited an army from Palestine, Syria and Transjordan to defend Jidda. Tahsin Pasha al Faqir, the commander of the so-called "Victory" division, organised a strong defensive position of trenches and barbed-wire entanglements in a semi-circle round the town. Ibn Saʿud himself arrived at Mecca in Dec. and the attack on Jidda began on Jan. 4 1925. The Wahhabis occupied the few villages outside the entrenched position, but had not succeeded in reducing the town at the end of June when the siege was temporarily raised to enable them to perform the pilgrimage. Meanwhile Ibn Saʿud, having occupied the ports of Qunfida and Lith south of Jidda and that of Rabigh north of it, extended his operations further north. Medina and its seaport Yenbo' were invested, while Umlaj, north of the latter, was occupied. On Dec. 5 Medina surrendered and Wejh followed suit. King ʿAli realised that his situation was hopeless and abdicated on Dec. 19. Jidda then surrendered simultaneously with Yenbo', and Ibn Saʿud was master of all Hejaz, of which he was formally proclaimed King at Mecca on Jan. 8 1926. For bibliography *see* Arabia. (H. St. J. B. P.)

HELFFERICH, KARL (1872–1924), German financier and politician, was born in Neustadt-on-the-Havel July 22 1872. In 1901 he became a professor of political science in Berlin, and in 1906 went to Constantinople as manager of the Anatolian Railway. He returned to Berlin in 1908 to take up the chairmanship of the Deutsche Bank. In 1913 he was the chief German delegate at the Paris conference for the settlement of Balkan financial affairs. In 1915 Helfferich was appointed Secretary of State for the Imperial Treasury, where he followed the principle of defraying the cost of the War by borrowing rather than by fresh taxation, relying on a final German victory. In June 191 he left the Treasury for the Home Office. In June 1918 he wa appointed to succeed Count Mirbach, who had been assassinated, as Germany's representative in Moscow. He was, however unable to occupy this post, and returned to Berlin to conduct th economic and industrial demobilisation of Germany after th Armistice. He was fatally injured in a railway accident nea Bellinzona April 23 1924.

HELICOPTER: *see* AIRSCREW.

HELIGOLAND BIGHT, BATTLE OF THE.—This naval actio was fought in the Bight on Aug. 28 1914 between British an German naval forces. According to the original British pla three submarines were to lie off Heligoland to attack Germa cruisers, while three others were to be posted to the west t entice their destroyers out. The Harwich flotillas were then t come in from the north and, sweeping on a nine miles front t the westward, were to cut off any light craft patrolling to th west of Heligoland. Adml. Jellicoe proposed to reinforce th flotilla with Vice-Adml. Beatty's battle cruisers and the 1st Light Cruiser Squadron. This proposal was only approved o Aug. 26 and, as there was no time to send the operation order north, Beatty left Scapa with only a general idea of the pla and no details of the intended movements of the submarines The forces from Harwich had already sailed and did not know that Beatty was on his way to reinforce them.

British Forces.—On Aug. 27 the British forces were all on their way to the Bight, organised as follows:—

TABLE I.

Sweeping Force (Commodore Reginald Tyrwhitt): "Arethusa," 2 6-in., 6 4-in., 28·5 knots; "Fearless," 10 4-in., 26 knots. Thir Flotilla, 1st, 2nd, 3rd and 4th Divs., 16 destroyers; First Flotilla, 1st, 2nd, 3rd and 5th Divs., 15 destroyers. Total: 2 light cruisers, 31 destroyers.

Submarine Force (Commodore Roger Keyes): "Lurcher," "Firedrake," E4, E5, E9 (off Heligoland); E6, E7, E8 (west of Heligoland).

Battle Cruiser Force (Vice-Adml. Sir David Beatty): 1st Battl Cruiser Sqn., "Lion," "Queen Mary," "Princess Royal," a 8 13·5-inch.

Light Cruiser Squadron (Commodore W. E. Goodenough) "Southampton," "Falmouth," both 8 6-in.; "Birmingham," "Nottingham," "Lowestoft," 9 6-in.; "Liverpool," 2 6-in., 1 4-inch.

Cruiser Force K (Rear-Adml. Sir A. G. Moore): "Invincible," "New Zealand," with four destroyers.

Cruiser Force C (Rear-Adml. A. Christian): "Euryalus," "Bacchante," "Cressy," "Hogue," "Aboukir," all 2 9·2-in., 12 6-in. "Amethyst," 12 4-in.

Total Forces: 5 battle cruisers, 9 light cruisers, 5 armoured cruisers, 37 destroyers, 6 submarines.

It was light at 4 A.M. Goodenough with the 1st Light Cruiser Squadron had met Tyrwhitt at 3:45 A.M. and was at first mistake for an enemy, but the cruisers were recognised in time. By A.M. the sun had risen, and the forces were in position some 6 m. northwest of Heligoland. It was a fine morning with a smooth sea and a gentle breeze blowing from the northwest. Beatty' battle cruisers were some 30 m. to the westward and all wa ready. The flotillas started off to the southeast at 20 knots, th "Arethusa" and 3rd Flotilla ahead, with the "Fearless" an 1st Flotilla 2 m. astern. The 1st Light Cruiser Squadron followe 8 m. behind. From a point 12 m. west of Heligoland, which h should reach at 8 A.M., Tyrwhitt intended to turn west and sweep anything in the Bight into his net. The Germans knew nothing of the impending attack. Posted round Heligoland i a semi-circle they had two lines of patrols, an outer line of nin destroyers 25 m. from the island and an inner line of older vessels (3rd Minesweeping Div.) 13 m. from it. These were supported by a flotilla at Heligoland, three cruisers on outpost duty, and a battleship in the Jade.

German Forces.—The German disposition in detail was a follows:—

TABLE II.

Outpost Forces: Outposts, Outer line, 9 destroyers; Inner line, 11 torpedo boats.

In Support of Outposts: 11 destroyers, 5th Flotilla (Heligoland). Light cruisers, "Stettin" (10 4·1-in.), "Hela," 4 4·1-in. (off

Heligoland), "Frauenlob," 10 4·1-in. (off Jade). Battleship, "Heligoland," 12 12-in. (in Jade).

In Wilhelmshaven Roads, Wilhelmshaven and off the Ems: Light cruisers, "Ariadne," "Kolberg," "Cöln" (Rear Adml. Maas, First Leader of Flotillas), "Strassburg," "Stralsund," "Rostock," "Mainz" (off the Ems). Battle cruisers, 1st Scouting Group, "Seydlitz," "Moltke," "Von der Tann," "Blucher." Battleships: 1st and 3rd Sqdns. (7 dreadnoughts).

Total Forces: 8 battleships, 4 battle cruisers, 10 light cruisers, 20 destroyers, 11 torpedo boats, 8 submarines.

The movements of the heavy German ships were governed ntirely by the time of low water on the outer Jade bar. This was at 9:33 A.M. and meant that between 7 A.M. and noon no German battleship nor battle cruiser could put to sea.

THE EARLY OPERATIONS

The activities of this eventful day started at 4:45 A.M. when the British submarine E7 fired a torpedo at the detroyer G194 patrolling some 25 m. northwest of Heligoland, nd Rear-Adml. Maas, the German flotilla admiral, at 6:45 A.M. ent out the 5th Flotilla from Heligoland to hunt the submarine. The sea was smooth, the sky overcast and weather dull. At 7:53 A.M. the "Arethusa" struck the outer patrol line and sent G194 flying towards Heligoland with the "Laurel" and her division in hot pursuit. They drew away to the east and at 7:26 A.M. Tyrwhitt turned to the southeast to support them. A few minutes later they sighted the German 5th Flotilla coming up, and sent it also flying back.

The report from G194 reached the German flagship about 7:30 A.M., and on it becoming clear that a considerable force of British destroyers had penetrated into the Bight, the light cruisers were ordered to proceed. The "Stettin" was already on her way at 7:58 A.M., though she had not raised a full head of steam. By this time the German 5th Flotilla was calling oudly for cruiser support. The alarm had gone at Heligoland, and by 7:50 A.M. the whole fortress was standing to its guns. The visibility was then about 16,000 yd., and German destroyers came into view driving pell-mell towards the island. The British were overhauling them. One of the destroyers had been hit in the stokehold at 7:50 A.M. and her position was becoming critical, when at 7:58 A.M. the "Stettin," coming round the north of Heligoland, appeared on the scene and opened fire on the "Laurel's" division at 9,300 yards. A 8:05 A.M. the "Fearless" sighted her and opened fire; the "Stettin" retired behind Heligoland to get up steam for full speed, while the "Fearless," receiving a signal at 8:12 A.M. to alter course to west-quarter-south, turned accordingly to begin the sweep.

This brief respite had enabled the German 5th Flotilla to get clear and they came streaming in towards Heligoland. The inner patrol line was under a heavy fire from the "Arethusa," and the torpedo boats D8 and T33 suffered severely, but at 8:08 A.M. the "Frauenlob" arrived on the scene from the south and engaged the "Arethusa" on a southwest course. A sharp action ensued at 6,500 to 4,000 yards. Only the forecastle gun of the "Arethusa" remained in action, and eight men were killed. The "Frauenlob" received some 10 hits and had nine killed and 28 wounded. At 8:25 A.M. the "Arethusa" turned to west-quarter-south and the "Frauenlob" turning south broke off the action.

The Second Phase (see fig. 1).—By 8:30 A.M. this phase of the operation was over and both flotillas were proceeding to the west with the "Fearless" some 6 m. north of the "Arethusa." Goodenough's light cruisers had also turned west at 8:30 A.M. and were some 12 m. to the westward. Beatty was moving to and fro with his battle cruisers about 45 m. to the northwest. The attack had not developed according to plan, for the German patrols had broken back and reached home with one exception. This was V187, the flotilla leader's boat, which the "Fearless" sighted to the westward at 8:15 A.M., and which was sunk after a hot chase by the "Goshawk," "Phoenix" and "Ferret" at 9:10 A.M. The destroyers had lowered boats to rescue the survivors, but the "Stettin," which had now got steam up, reappeared on the scene and drove them off. Five boats in the scurry had to be left behind, but E4 (Lt.-Comm. E. W. Leir), emerging suddenly, rescued the "Defender's" men, took an officer and two of V187's crew "as a sample," then disappeared as suddenly and silently as she came. By 8:55 A.M. the "Fearless" had rejoined the "Arethusa" and the flotillas were now from 12 to 15 m. west of Heligoland steering west-quarter-south.

Commodore Keyes, in the "Lurcher," not knowing Goodenough's cruisers were on the scene, had mistaken them for the enemy and asked for help, but recognised them at 10 A.M., and as the "Southampton" had already attempted to ram E6, Goodenough decided to withdraw to the west and leave the field clear for the submarines. Tyrwhitt had turned boldly back to help Keyes at 9:45 A.M. The "Arethusa" stopped for repairs at 10:17; her engines were disabled and she was only able to go 10 knots. A lull of half an hour ensued. By this time the Germans were beginning to appreciate the situation. At 8:20 A.M. the commander-in-chief, Adml. von Ingenohl, had taken over the command from Hipper, the admiral of scouting forces, and had ordered the battle cruisers to raise steam and to proceed as soon as there was water on the bar. The German light cruisers, eager to attack, were pushing out as soon as they could raise steam. They now began to appear on the scene.

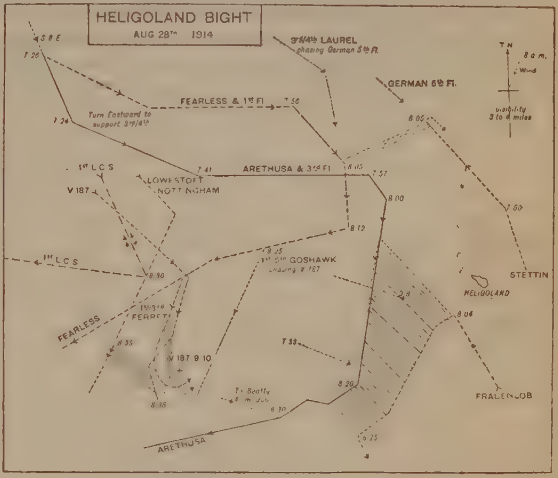

FIG. 1.—Flotillas at 8:30 A.M.

The "Arethusa" had got under way again at 10:40 A.M. and was making slowly to the west when at 10:46 A.M. the "Strassburg," which was trying to get in touch with the "Stettin," appeared in the southeast, coming up on a north-north-west course. She opened fire at about 8,400 yd., crossed the "Arethusa's" stern, turned and disappeared to the north in the mist. The "Cöln" had come up behind her at 11:5 A.M., but after exchanging a few salvos she too passed on. At 11:16 A.M. the "Strassburg" reappeared to the north and steering a parallel course to the west opened a heavy fire at 8,650 yards. The 1st and 2nd Divs. of the 3rd Flotilla went off to the northwest and, joined by the 1st Div. of the 1st Flotilla, attacked her at 11:35 A.M. Two torpedoes ran past her and she disappeared in the mist. The destroyers rejoined the "Arethusa" and continued their course to the westward.

When the "Cöln" appeared Tyrwhitt had signalled for support, and when the "Strassburg" came in sight the second time, Capt. Blunt of the "Fearless," foreseeing the concentration which the German light cruisers were striving to achieve in the mist, sent an urgent signal to Beatty for assistance. Beatty had been waiting and watching round a position in 54° 28′ N., 6° 20′ East. The situation was obscure, but between 11 and 11:30 A.M. it was clear that Tyrwhitt was engaging a cruiser some 30 m. to the eastward, and at 11:20 A.M. Goodenough was ordered to support him. Then came Capt. Blunt's signal from the "Fearless" couched in terms of urgency. Beatty did not know that the "Arethusa" could only go 10 knots, but he knew that the flotillas were only 26 m. from Heligoland, and that the German base at Emden lay close to their flank. He decided at once to take his whole force in the Bight. At 11:24 A.M. his battle cruisers had been formed in single line ahead, and working up to full speed he proceeded east-south-east to throw their tremendous weight into the issue of the day.

The Main Action

The " Mainz " had left the Ems shortly after 7 A.M. and was making at full speed to the east to cut off the British destroyers and to join the " Strassburg " and the " Stettin." At 11:30 A.M. she was sighted almost right ahead by the 2nd, 3rd and 5th Divs. of the British 1st Flotilla as they came west with the " Fearless " and " Arethusa " some miles behind. The " Mainz" turned to the north and opening a heavy fire chased the destroyers to the north for 20 minutes. But at 11:50 A.M. the situation suddenly changed. Out of the mist to the north-northwest there appeared four light cruisers coming down at high speed. They were Goodenough's cruisers. For an anxious minute the destroyers were uncertain whether they were friend or foe, then they recognised them and turned eagerly to join them. The " Mainz " recognised them too and fled to the southward at 25 knots. The range was over 7,000 yd.; she received two hits and drew away in the mist, sending at noon a signal—the last she sent—that she was being chased by a battle cruiser. It was received at 12:05 P.M. and the " Moltke " and " Von der Tann " were ordered to proceed, screened by the German 8th Flotilla. In the river it was clear, and no one had informed the German command of the mist prevailing in the Bight. The " Mainz," running to the southeast had hardly drawn away from the light cruisers when at 12:08 P.M. she sighted the " Fearless " and the 3rd Flotilla coming west. She swung round to south as the 1st and 2nd Divs. of the British 3rd Flotilla turned to north and the 4th Div. to south to engage her.

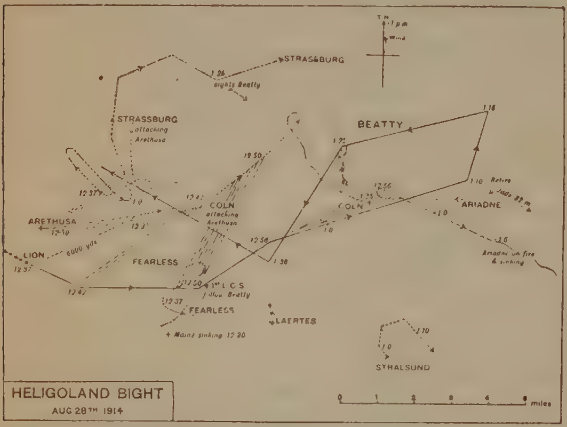

FIG. 2.—Beatty Enters the Fight.

Sinking of the " Mainz."—In the action that ensued the " Mainz's " rudder was damaged and her port engine brought to a stop. She then concentrated her fire on the 4th Div. at about 5,000 yards. The " Laurel " was hit by the first salvo; the fourth blew up a number of lyddite shells, and with her captain severely wounded and her after funnel blown away, she crawled away hidden in her own smoke and steam. The " Liberty " had her mast shot away and her captain killed. The " Laertes " was hit four times by a single salvo at 4,000 yd., and stopped dead. But the " Mainz " had been hit at 12:15 P.M. on the port side amidships by a torpedo fired by one of the destroyers, and Goodenough's cruisers which were now closing, opened a deadly fire which reduced her quickly to a wreck. At 12:25 P.M. they ceased fire; the " Lurcher " coming alongside saved her crew and at 1:08 P.M. she settled by the bows and sank.

British Battle Cruisers in Action.—The situation was still far from clear; the flotillas were scattered; the " Strassburg " and " Cöln " had appeared to the northeast and opened a heavy fire. Then suddenly out of the mist there emerged Beatty's fou great battle cruisers steaming at high speed. They swept pas the sinking " Mainz " and on to the northeast with Goodenoug and his light cruisers following in their wake. The Germa cruisers fled, but it was too late. At 12:37 P.M. the " Lion ' sighted the " Cöln " on the port bow and opened fire at 3,80 yd.; the " Cöln " ran desperately to the northeast, but a heav shell disabled her engines. Then she gained a brief respite, fo the " Ariadne " was sighted by the " Lion " trying to cross he bows on a southeast course. Fire was opened on her. She wa hit by the first two salvos and disappeared in the mist to th southeast, on fire and sinking.

Beatty now decided to withdraw, and at 1:10 P.M. made th signal to retire. The " Lion " came gradually round to a westerly course and at 1:25 P.M. sighted the " Cöln " again, steerin slowly to the southeast. Her admiral had fallen; her captai was seriously wounded. The " Lion " sent a 13·5-in. shell int her; she listed to port and sank with flag flying at 1:35 P.M. B this time both the " Stettin " and " Strassburg " had sighted and reported the British battle cruisers, and at 1:50 P.M. th German light cruisers were ordered to fall back on the " Moltke ' and " Von der Tann." It was not, however, till 2 P.M. that th battle cruisers passed the bar of the Outer Jade. The Germa battleships were then raising steam, and the battle cruisers wer ordered (2:41 P.M.) not to advance against the British, but t wait for the " Seydlitz " 25 m. west of Heligoland.

By 3:50 P.M. the three German battle cruisers had reache that position, and there they were joined by the " Strassburg," " Kolberg " and " Stralsund." They made a short sally, bu there were no signs of any British ships, and they turned bac before reaching the spot where the " Cöln " had sunk. For th British it remained only to get home. At 4:30 P.M. Rear-Adml. Campbell's cruisers met the destroyers and the " Laurel " wa taken in tow by " Amethyst." The " Arethusa " struggled o at six knots till 7 P.M., then signalled for assistance, and at 9:30 P.M. was taken in tow by the " Hogue " and returned safely.

Results of the Battle.—Mist, uncertainty and the speed of th German light cruisers had hampered the British submarines. The German submarines had all been held back off Heligolan and by the time they were finally dispatched to attack th British battle cruisers, the latter were out of reach. The engagement was a severe blow to the German fleet. They los three light cruisers and one destroyer, and their casualties wer 63 officers and 649 men killed, 20 officers and 361 men wounded, nine officers and 140 men prisoners; a total of 1,242 against th British 35 killed and some 40 wounded.

The engagement had important ulterior consequences. Whe Beatty swooped down on the Bight, he drove a great wedg into German naval policy, for the loss of the cruisers confirme the Kaiser in his determination to restrict the German fleet t a strictly defensive policy. For the British Navy and Natio the victory came at an opportune time. The irresistible advanc of the German Army had filled many with something like dismay. The news of a naval victory at the very gates of the enem lightened the gloom, and gave the nation faith in the navy' ability to face its gigantic task.

HELIOTHERAPY (*see* PUBLIC HEALTH; THERAPEUTICS).— Heliotherapy, or treatment by sunlight, has been intermittentl practised since the dawn of history, but its scientific exploitatio dates from the time of Finsen, who especially developed light treatment by the employment of artificial sources of light, notably the carbon arc. It owes much to the work of Bernhard an Rollier, who commenced treatment with natural sunlight earl in the present century. The latter especially, by the brillianc of his results and his enthusiastic advocacy, has done much to popularise its use, especially in nonpulmonary tuberculosis.

Its employment on an extensive scale in Great Britain was initiated with the establishment of the Treloar Cripples' Hospital at Alton. It was employed to some extent with gratifying results on septic wounds contracted during the War, but interest s been especially aroused since that period, the abnormally e summer of 1921 and the institution of Daylight Saving ling general notice to the importance and significance of sun-ht in our lives both in health and disease. Further researches numerous investigators have done much to demonstrate the nner in which sunlight is of therapeutic value.

Essential Conditions.—The most obvious benefits are noted by nical observation on patients suitably exposed to solar rays. rtain essentials are necessary to demonstrate these beneficial sults. The patient exposed to the sunlight should first be climatised; he must never be too hot or too cold; in brilliant nshine his head should be protected, and if there is much glare s eyes should be shielded by dark goggles. Exposure should gradual: first the feet are sunned for short periods daily, the gth of exposure and the area exposed being increased slowly, that at the end of a fortnight exposure of the whole body may generally tolerated with safety. Periods of exposure are adually lengthened, until eventually the patients are often le to tolerate and benefit by exposure of the nude skin for from ree to four hours daily.

There are great variations in the optimum exposure of dif-rent individuals. Generally speaking, brunettes tolerate ex-osure better than blondes; individuals who freckle but whose ins do not brown must be exposed with great caution, while binos can barely tolerate exposure at all. On the normal skin erythema develops within six hours of exposure; care should taken not to exceed this erythema, and blistering is to be oided. Gradually the skin becomes bronzed, and as this onzing or pigmentation deepens so may exposure be pro-nged, the pigment protecting the patient from the harmful fects of the actinic rays.

Insolation necessarily involves exposure of the body to the ld air, and the latter has been shown to increase the meta-lic activity of the subject treated. The rays of greatest thera-eutic value are the ultra-violet or actinic rays, the light waves shortest wave-length in the solar spectrum. These are most tense at the seaside or on the mountains. Excess of heat rays to be avoided, and insolation for its therapeutic value is thus tter carried out in temperate than in tropic regions. Properly med exposure on the individual responding to treatment is sociated with a tonic and exhilarating effect; exposure unduly rolonged results in fatigue and exhaustion, and is to be avoided.

Effects of Insolation.—While properly applied insolation ex-cises a tonic effect on the body, it has been demonstrated that is equally stimulating to the mind. The exposed subject is otably more cheerful and exhilarated, and evidence has been lduced to show that mental responses are brisker and mental tivities more pronounced. On the body the effect of insolation ay be described as local or direct and remote or indirect. ight exercises a beneficial effect on superficial lesions by reason f the direct bactericidal action of the actinic rays, assisted by he favourable inflammatory response which carefully timed xposure elicits.

The remote beneficial effects are more marked but less easy to xplain. Eidenow has shown that the haemobactericidal power often raised after an erythema dose. This enhanced power of he blood to destroy pathogenic organisms is obtainable equally hen a portion or the whole of the skin is exposed, and, if in-reased haemobactericidal power is alone sought, fractional xposures of different portions of the skin at consecutive sessions the method of treatment of choice. Sonne has demonstrated hat the visible rays of the solar spectrum have considerable enetrative power, pass through the skin, and are absorbed in the ubjacent blood, their physical being transformed into thermal nergy. He has suggested that this local heating effect is of value n destroying deleterious circulating toxins. Investigations have hown that the calcium, phosphorus and iron content of the blood nay be raised by insolation.

Sunlight treatment has its greatest therapeutic value in in-reasing and maintaining bodily tone and energy, in the treatment of the various manifestations of surgical tuberculosis, in he treatment of rickets and the relief of nervous asthma. It is of proved value in certain affections of the skin, notably psoriasis. It is of great assistance in a variety of conditions, accelerating and consolidating the cure, particularly in convalescence from debilitating diseases such as infectious fevers. Its stimulating effect is seen in increasing fecundity and in the treatment of certain defects of the endocrine glands. The range of its usefulness is being rapidly extended, in the main, as an aid to cure rather than as a specific treatment. See A. Rollier and others, *Heliotherapy* (1923). (H. J. G.)

HELIUM (*see* 13.233).—Helium, next to hydrogen, is the lightest of all the chemical elements. Except at exceedingly low temperatures, it exists only in the gaseous form.

Sources of Helium.—Investigations carried out since 1895 have shown that helium is widely diffused throughout the earth. It can be obtained from many types of rocks, minerals and earths, and it is present in varying amounts in probably all natural gases and spring waters. It is present, too, in the atmosphere of the earth to the extent of about one part in 185,000 by volume. Evidence that helium is universally distributed is afforded by the fact that many of the white stars exhibit its absorption spectrum, while certain other stars and nebulae show the bright line spectrum of the gas. Helium has also been found in a meteorite that reached the earth at Augusta Co., Va., United States of America.

Helium from Rocks and Minerals.—In the case of most of the rocks and minerals that contain helium in appreciable amounts the gas is present as a result of the radioactive disintegration of the uranium or of the thorium present in them. Of all the minerals examined, thorianite, which consists chiefly of thorium oxide, is probably the richest in helium. It has been found to contain 9·5 cu. cm. of helium per gramme.

Monazite, a phosphate of thorium and other rare earths, contains on the average about 1 cu. cm. per gramme. Cleveite, samarskite and fergusonite contain a little more than monazite. Helium is found in minute quantities in practically all the common minerals of the earth, and its origin in them has been traced to radioactive matter that is universally distributed in minute amounts in the material constituents of the earth's crust. In two cases helium has been found in minerals in the absence of appreciable amounts of uranium and thorium compounds, namely in beryl and in sylvine (potassium chloride). It is interesting to note, however, in this connection that potassium and rubidium in their elemental state as well as in the form of chemical compounds have been shown to be radioactive at least to the extent of emitting beta rays. In extracting helium from the mineral thorianite, which is imported from Ceylon usually for the manufacture of thoria, the method generally followed is that given by Lord Rayleigh. The mineral dissolves readily in strong nitric acid, and the helium contained is then liberated. The gas contains a certain amount of hydrogen and of oxides of carbon, also traces of nitrogen. To get rid of carbon some oxygen is added to the helium and the mixture is exploded with an electric spark.

All the remaining impurities, including the excess of oxygen, can then be taken out of the gas by Sir James Dewar's ingenious method of absorption with charcoal cooled in liquid air. Helium is but slightly absorbed by the cold charcoal, and consequently can be pumped off from the vessel containing the charcoal in a state of the highest purity. If liquid air is not available helium can be purified by the methods employed for argon, the various impurities present being removed by one or other of the agents —calcium carbide or metallic calcium, copper oxide, caustic potash and phosphorus pentoxide. If thorianite is not available, monazite, which is more abundant, may be utilised. In 1895 Lockyer showed that the helium contained in minerals could be extracted from them by heat; J. A. Gray (*Proc. Roy. Soc.*, 82A, p. 301, 1909) confirmed this discovery at a later date, and showed that helium could also be extracted by simply grinding the minerals into a fine state of division.

Helium from the Atmosphere.—Helium may be extracted from the atmosphere by passing ordinary air through tubes cooled with liquid hydrogen. At the temperature of liquid hydrogen all elements in the air become solidified excepting helium, and the latter, after passing through the tubes, can be collected in a highly purified state. In the process of the liquefaction of air, or in that of extracting nitrogen or oxygen from the air by liquefaction and rectification in large industrial plants, it has been found feasible to include in the machines used for the purpose devices that allow the helium and the neon of the air to be separated out, these two gases being the only constituents of the atmosphere that remain in the gaseous form when air is liquefied. As charcoal cooled with liquid air has more condensing power for neon than for helium, it is generally used to separate out the helium from a mixture of these two gases. Final purification, however, is best effected by the use of liquid hydrogen.

Helium from Mineral Springs and Natural Gases.—Helium is found in the gases evolved from many thermal water springs. Moureu and Lepape, who made an exhaustive determination of the helium content of the gases evolved from mineral springs in France, found that many of them contained a considerable proportion of helium. At one spring in Maizières it amounted to 5·92%, and at two others in Santenay (Côte d'Or) helium contents of 8·4% and 9·76% by volume were found. In the hot springs of Bath, England, the helium amounts to about one-thousandth part of the gas evolved. Traces of helium have been found in the gases of the thermal springs in Iceland, and also in many of the natural gases of the other countries in Europe. The quantities involved in the latter, however, are extremely small and the occurrences unimportant. Lord Rayleigh has suggested that the helium found in hot springs may be derived from the disintegration of common rocks at great depths.

By far the best practical sources of helium are the natural gases of America. In Canada, while natural gases are found in all the provinces, they exist in commercial quantities only in the provinces of Alberta, Ontario and New Brunswick. The helium content of these gases has been determined on several occasions, and the latest results are those given by the Mines Branch of the Dept. of Mines of Canada. This report shows that while helium is found in all the Canadian gases it has not been found to be present in any of them to a greater extent than 1%. A conservative estimate of the amount of helium recoverable from the natural gases of Canada would be 5,000,000 cu. ft. per annum.

In the United States of America the main helium resources occur in the Texas, Mid-continent and Appalachian natural gas-fields, where the supplies of helium-bearing gas are widely distributed, and where in some localities they are of great magnitude. The helium content of the gases from a majority of the wells is not greater than 0·6%, but in Kansas a number of wells exist that give a supply of natural gas containing from 1·5% to 1·84% of helium. It is estimated that it would be possible to extract nearly 50,000,000 cu. ft. of helium yearly from the natural gases of the United States.

Properties of Helium.—Helium is less soluble in water than any other gas, and recent determinations by Antropoff give the following values for its solubility: 0° C. ·00967, 10° C. ·00991, 20° C. ·00996, 30° C. ·01007, 40° C. ·01029, 50° C. ·0108. Quartz glass at a red heat is freely permeable to helium. The effect is even perceptible at a temperature as low as 180° Centigrade. At 500° C. quartz glass has been shown by Williams and Ferguson to be 22 times as permeable to helium as to hydrogen (*Jour. of Am. Chem. Soc.*, Oct. 1922). This property has been put forward as the basis of a practical method of separating helium from other gases. M. Travers has suggested, also, that it may explain the liberation of helium from minerals by heat, the gas being enabled to permeate the siliceous materials in which it is enclosed. Thorianite, however, contains no silica, and until it is shown that metallic oxides are permeable to the gas this explanation can scarcely be accepted as valid. With rubbered balloon fabrics the permeability to helium has been found to be less than to hydrogen, the ratio of helium to hydrogen permeability being about 0·7. With skin-lined fabrics the ratio of helium to hydrogen permeability has been found to be about unity. The temperature coefficient of increase of pressure at constant volume is perfectly normal for helium, and has a value of 0·0036614 (Fourth Int. Cong. on Refrigeration, June 1924). The thermal conductivity at 0° C. is given by Schwarze as 0·0003386, and the viscosity as determined by Schultze at 15° C. is 1·086 compared with that air as unity. This determination has been confirmed by Rankin

The velocity of sound in helium at 0° C. is 971 metres per se and the ratio of the specific heats, C_p/C_v, has the value 1·6 at 180° C. and 1·659 at 18° C., which indicates the monatom character of the gas. At 18° C. the specific heat at constant pre sure, C_p, is 1·251, and the atomic heat consequently 5·004. T refractive index of helium at normal pressure and temperatu for the wave-length 5890Å is 1·000035. Helium has two res nance potentials, 19·77 volts and 20·5 volts, and its ionisati potential is 24·5 volts. The minimum sparking potential f helium is 261 volts. Gaseous helium at normal pressure ar temperature has for its dielectric constant 1·000074. Helium a gas is diamagnetic, and according to Hector (*Phys. Rev.*, Oc 1924, p. 148) it has a volume magnetic susceptibility of $-0{\cdot}78$ 10^{10} at 20° C. and 760 mm. pressure.

Helium Atoms and Nuclei.—The atomic weight of helium 4, and its density is 1·995. Since the gas is monatomic its atom and molecular weights are the same. Of all the rare gases heliu alone has no isotopes (*q.v.*). The square root G of the mean squa molecular velocity of the atoms of gaseous helium at 0° C. $13{\cdot}11\times10^{4}$ cm. sec^{-1} and the mean free path at normal pressu and temperature is $28{\cdot}5\times10^{-6}$ centimetre. The molecular dian eter as deduced from the viscosity of the gas is $2{\cdot}18\times10^{-8}$ centi metre. Like the atoms of other elements, those of helium have nuclear structure, the positive electric charge on the heliu nuclei being 2ϵ where ϵ is the elemental charge of electricity. Th two electrons that neutralise the nuclear charge are supposed t describe about the nucleus two nearly circular orbits with plan that are inclined to each other at an angle of 120°. The radiu of these orbits is approximately $1{\cdot}25\times10^{-9}$ centimetre. Spec troscopic evidence goes to show that while helium in its norma state exists in the form of atoms with crossed electronic orbits can also, under electric excitation, be transformed into a meta stable state designated as orthohelium. With atoms in the latte state the electronic orbits are supposed to be in the same plan with one orbit circular and the other elliptical, the major axis o the elliptical orbit being approximately four times as great as th diameter of the circular one.

For spectroscopic purposes helium, with its atoms in th normal state, is sometimes given the designation parhelium The alpha rays expelled by radioactive substances have bee shown to be helium nuclei. The initial velocities with which they are expelled from such substances vary from $2{\cdot}22\times10^{9}$ cm. sec^{-1} to $1{\cdot}45\times10^{9}$ cm. sec^{-1} according to the radioactive substance that gives rise to them. The corresponding kinetic energies are $1{\cdot}53\times10^{-5}$ and $0{\cdot}645\times10^{-5}$ ergs. It was by observations on the scattering of alpha rays of very high speeds through large angles by thin sheets of matter that Rutherford in 1911 established the view that atoms generally possess a nuclear structure.

Through phenomena associated with this scattering of alpha rays by matter it has been shown that the nucleus of a helium atom possesses very great stability. Helium nuclei themselves are supposed to be complex in their structure and to consist of four hydrogen nuclei and two electrons. Numerous experiments lead one to take the view that a helium nucleus or alpha particle behaves in impacts with nuclei of other atoms as if it were a perfectly elastic body, spheroidal in shape, with its minor axis 4×10^{-13} cm. in the direction of motion and its major axis $8\times$ 10^{-13} centimetre. The mass of a helium atom is slightly less than the combined masses of the hydrogen nuclei and electrons of which it is constituted, and this indicates that a large amount of energy must be liberated during its formation in the form of radiation of wave-length approximately $1{\cdot}75\times10^{-11}$ centimetre. A view held by astrophysicists generally is that the exceedingly high temperature of certain stars that exhibit a helium hydrogen spectrum can be accounted for by assuming them to be the seat of the formation of helium out of hydrogen. By bombarding the nuclei of the atoms of various elements with alpha rays, Rutherford has proved that atomic nuclei generally have a complex structure with hydrogen nuclei and electrons as primary constituents, and in some cases with helium nuclei as secondary ones.

Liquid Helium.—The liquefaction of helium was achieved H. Kammerlingh Onnes at Leyden in 1908. In Jan. 1922 a rogenic laboratory was instituted in the University of Toronto d helium was liquefied in Jan. 1923. Finally, in the summer 1925 helium was liquefied in small quantities in the Reichs- stalt, Charlottenburg, Germany. Liquid helium is a colour- s, very mobile liquid with a low surface tension. According Onnes and Boks (*Leyden, Comm.*, No. 170) the density of uid helium has a maximum value of 0·1462 at 2°·39 K with a lue 0·1404 at 3°·19 K. and one of 0·1456 at 1°·49 K. assuming e absolute zero to be −273°·09 Centigrade.

The saturation vapour pressure (p. in mm.) of liquid helium is 15 at 1°·475 K., 359·5 at 3°·516 K., 757·5 at 4°·205 K., 1329 4°·9 K. and 1668 at 5°·16 Kelvin. The heat of vapourisa- n at 4°·25 K. has been estimated to be 19·38 gr. calories. e critical temperature of helium is 5°·19 K., the critical pres- re (p. in Int. Atm.) 2·26, and the critical density 0·066. The slope diameter" is −0·0033 and the boiling point at atmos- eric pressure is 4°·21 Kelvin. The triple point temperature d pressure (p. in Int. Atm.) are respectively less than 0°·89 K. d 0·002 (see *Report* of Fourth Int. Cong. on Refrigeration, ne 1924). According to Kammerlingh Onnes the Boyle point s close to 20° K. and the "inversion temperature" to 40° elvin.

From certain considerations brought forward by Perry (*Jour. Phys. Chem.*, vol. 28, No. 10, Oct. 1924) it can be shown that e optimum working pressure to use when liquefying helium, ter cooling it with liquid hydrogen, is between 15 and 20 atmos- eres. The lowest temperature attained by H. Kammerlingh nnes with liquid helium boiling under low pressure was a few ndredths of a degree below 0°·9 kalium. The vapour pressure rresponding to this temperature was estimated to be 0·013 illimetres of mercury.

Liquid helium has been extensively used as a refrigerating gent by H. Kammerlingh Onnes and his collaborators and by hers when investigating the physical and chemical properties various substances at the lowest attainable temperature. hough the great majority of the investigations carried out have en connected with the thermal properties of substances, others aling with the phenomena of phosphorescence and fluorescence, agnetism and magneto-optics, crystal structure, radioactivity d electrical conductivity have led to results of great scientific lue. Probably the most interesting phenomenon discovered d investigated by H. Kammerlingh Onnes through the use of uid helium is that of electrical super-conductivity in metals. this field of investigation Onnes has shown that at tempera- res attainable only with liquid helium the metals mercury, ad, tin, indium and thallium offer no resistance to the passage electric currents through them and become perfect electrical nductors. It may be added that up to 1926 helium, alone of the elements, had not been solidified.

Chemical Activity of Helium.—Although helium is chemically ert under ordinary conditions, evidence obtained in recent ears suggests the possibility of its exhibiting chemical activity nder certain very special conditions. Particularly under the fluence of the electrical discharge, helium atoms may be united ith other helium atoms in the same state or with atoms of other ements, to form compounds either of a fugitive or a permanent haracter. The fact that helium under certain conditions can be ade to emit a band spectrum in addition to its line spectrum notes the possibility of the gas existing in the molecular form.

Experiments made by E. H. Boomer (*Proc. Roy. Soc.*, vol. 09, No. A 749, p. 198) with an intense electric discharge from incandescent tungsten filament in helium at low pressures ow that a distinct and stable compound can be formed out of ngsten and helium with the formula $W He_2$. Boomer has also tained evidence of chemical combination of helium with the apours of mercury, iodine, phosphorus and sulphur. These mpounds are fugitive in character and appear to be stable only very low temperatures.

Industrial Uses.—In 1914 Sir Richard Threlfall put forward suggestion to the Board of Inventions of the British Admiralty, that if helium were available in large amounts it might be used to replace hydrogen as a filling for airships. The fact that helium is non-inflammable and non-explosive and possesses 92% of the lifting power of hydrogen makes it a most suitable material for giving buoyancy to airships. Following up the suggestion, Prof. McLennan and his associate, Mr. John Patterson initiated experiments for the British Admiralty on a semi-commercial scale on the natural gases of Canada. A machine was designed, constructed and successfully operated, with results that showed it was quite feasible to extract helium economically from natural gases when helium was present in them to the extent of only 0·33%. At the same time vastly greater experiments were initiated and carried through independently by the military and naval authorities of the United States, in co-operation with the Bureau of Mines of that country. Enormous quantities of helium were extracted from the natural gases of Texas, and the possibility of separating out the helium from the natural gases at a low cost was fully demonstrated.

In the electrical industry helium may be used for the construction of thermionic amplifying valves of the ionisation type and of gas arc lamps. In spectroscopy, especially for investigations in the ultra-violet region, helium is of use and possesses an advantage over most other gases in that it is transparent to light of extremely short wave-lengths. Owing to its high dielectric properties and its high heat conductivity it has been proposed to use helium in place of oil as a filling for transformers and for surrounding the switches and circuit-breakers of high tension electric transmission lines. Tests have been made by the General Electric Co. of the United States on the use of hydrogen as a cooling medium for large electric generators. These machines were operated in an atmosphere of hydrogen, with the result that owing to the lightness of hydrogen the windage loss was reduced, and owing to its high heat conductivity compared with air, the generators were made to give a 30% greater output with the same temperature rise. Since helium is also a light gas with a thermal conductivity slightly greater than that of hydrogen and can be used without the danger of explosions occurring, it would appear that it may be used for the same purpose if obtainable in large quantities at a low cost.

In 1917 considering the hygiene of labor, it was suggested by Elihu Thomson and others that if divers and workers in tunnelling operations carried on under high atmospheric pressures were supplied with a mixture of oxygen and helium in place of air the liability to caisson disease might be minimised or perhaps eliminated. Preliminary tests made in this direction by R. R. Sayers, W. P. Yant and J. H. Hildebrand for the United States Bureau of Mines (*Reports of Investigations*, Serial No. 2,670) have shown that through the use of helium and oxygen mixtures as a substitute for air in diving work the time of decompression can be materially reduced. This results from the fact that helium diffuses more readily out of the blood and body tissues than nitrogen. As the depths at which divers can operate depend largely on the duration of the period of decompression these experiments open up the possibility for extending somewhat the safety depth limit for diving operations.

Spectra Modified by Action of Helium.—A number of investigators, including Merton, Barrett, Johnson, Cameron and others, have shown that profound modifications may be observed in the spectrum of an element when it is present in small quantities in a discharge tube containing helium at a comparatively high pressure. As an example, the "comet-tail" spectrum discovered by Fowler is greatly enhanced by high-pressure helium. Merton and Pilley, too, were able with the addition of helium not only to bring out the hitherto practically unknown arc spectrum of atomic nitrogen, but also to isolate it completely from the spark spectrum of this element. McLennan and Shrum recently made some observations on the spectrum of small quantities of air in a large admixture of helium, and analysis of the spectrum obtained by them with these mixtures showed the presence of a line at $\lambda = 5577\cdot35$ Ångström units. When mixtures of oxygen and helium were used and an uncondensed discharge passed through, the line $\lambda = 5577\cdot35$ Å. was enhanced.

The line was obtained with the strongest intensity when the partial pressure of the oxygen in the mixture was about $\frac{1}{25}$ that of helium, the partial pressure of the latter being about three centimetres. The line was also obtained with pure oxygen, which shows that it belongs to the spectrum of this element. As the intensity of the line when obtained with pure oxygen is low, it would appear that the function of the helium is to maintain the oxygen atoms in a state that permits them to radiate the light $\lambda=5577{\cdot}35$ when once they are brought into that state by electrical stimulation. These results have a bearing on problems connected with the identification of the lines in the auroral spectrum, and McLennan and Shrum's experiments are of interest in that the wave-length $\lambda=5577{\cdot}35$ Å. which they obtained with oxygen is identical with that of the green line in the spectra of auroras that has long defied identification. The result is also interesting in that it may be taken as evidence of the existence of helium containing a small amount of oxygen in the upper atmosphere, for it is known that auroral displays originate at atmospheric heights of about 100 kilometres.

The Spectrum of Helium.—Both theory and experiment indicate that in the ultra-violet spectral region the radiation emissible by helium does not include any wave-length shorter than $\lambda=228$ Ångström units. The line spectrum of helium as observed ordinarily in vacuum tubes consists of a system of singlet series and a system of doublets. The doublets are very close and are somewhat unusual in that in the sharp diffuse series the more intense component is on the more refrangible side, while the first principal line has its stronger component on the side of the greater wave-length. It is generally accepted by spectroscopists that the singlet series of wave-lengths in the spectrum of helium originate in parhelium, and that the doublet series have their origin in atoms in the metastable or orthohelium state. Besides the line spectrum there is, as previously stated, an interesting band spectrum of helium which is well developed under appropriate conditions. Fowler has shown that the heads of some of the stronger bands, in contrast with all other known band spectra, are arranged in accordance with the laws of line series. There is, however, no apparent relation between the band and the line series, except that the main series of bands runs nearly parallel with the principal series of helium doublets.

All lines in the helium spectrum that have been investigated are resolvable by magnetic fields into normal Zeeman triplets. Recently Curtis and Jevons (*Nature*, Nov. 21 1925) showed that a Zeeman effect can be obtained with certain lines in the band spectrum of helium. The wave-lengths of a number of lines in the spectrum of helium were accurately measured by Merrill at the Bureau of Standards, Washington (*Astrophys. Jour.*, 46, p. 357, 1917) and are now accepted as secondary standards for the purpose of spectrum analysis. They are as follows:—

(I.A.)	(I.A.)	(I.A.)
2945·104	4026·189	4921·929
3187·743	4120·812	5015·675
3613·641	4143·759	5047·736
3705·003	4387·928	5875·618
3819·606	4437·549	6678·149
3888·646	4471·477	7065·188
3964·727	4713·143	7281·349

BIBLIOGRAPHY.—An extensive bibliography of the work on helium is given in *Circular* of the Bureau of Standards, Washington, No. 81 (1919).

For the results of low-temperature investigations the *Communications* from the Physical Laboratory of the University of Leyden should be consulted. (J. C. McL.)

HELSINGFORS or HELSINKI (*see* 13.252), the capital, chief seaport and only large town of the republic of Finland, had a population in 1922 of 201,435. The chief buildings are largely classical in style, but a number of modern ones showing the national spirit by using local materials and peasant decorative motives, have been erected, in particular a church overlooking the town, the cyclopean parliament buildings on the heights of Brunnparken, a new railway station and a fine memorial to those who fell in the Finnish fight for freedom. The town is an industrial centre, and the harbour accommodates the largest
vessels, but it is usually closed by ice from Jan. to the end
April, except for a channel kept open by an ice-breaker. T
harbour has been much improved in recent years, and had ov
7,000 yd. of quays in 1924; in 1925 a coal wharf was in ere
tion, and a goods station was to be built alongside the harbou

in maintaining the "splendid unity" of the nation.

When the first Coalition Ministry was formed by Mr. Asqui
in 1915, Mr. Henderson was included in the Cabinet mainly
adviser of the Government on labour questions arising out
the World War, with the office, first of President of the Board
Education, and afterwards of Paymaster General. He show
himself resolved on a strenuous prosecution of the War, strong
advocating both the Munitions Bill and the Registration Bi
and having no hesitation in taking the further step of comp
sory service. He followed up this action by urging the Labo
party to rally in Dec. 1916 to Mr. Lloyd George, and by accep
ing himself the position of an original member of the War Ca
net of four without portfolio. In the spring of 1917 he visit
Russia, just after the Revolution, on behalf of the British Gov
and found the then provisional Govt. at St. Petersburg (Len
grad) strongly in favour of an international Labour and Social
conference, which was to meet at Stockholm under the auspi
of the International Socialist Bureau. He came to the conclus
that, provided the Conference were merely consultative,
would be better that British representatives should go, rath
than permit Russian representatives to meet German represen
atives there alone; and accordingly, on his return to Englan
being still secretary of the Labour party as well as a member
the War Cabinet, he promoted the participation of Briti
Labour therein. But public opinion in general was strong
against any conference with Germans in the midst of war; t
Sailors and Firemen's Union refused to carry the delegate
French, Belgian, Italian and American Labour declined to ha
anything to do with the conference; and all his Labour colleagu
in the Government opposed his views. On Mr. Lloyd Geor
expressing the surprise of the rest of the War Cabinet at h
action, and their dissent from his policy, he resigned.

Mr. Henderson warmly espoused the Labour decision of t
latter part of 1918 to take the Labour men out of the governme
and to appeal for support on a purely Labour platform in co
junction with the pacifist wing of the party. This cost him h
seat in Parliament at the general election of Dec. 1918, when n
pacifist Labour candidates were successful. Indeed, ill-luc
pursued him also at the next two general elections, in 1922 an
1923; but in all three cases he returned to the House of Commo
a few months later at a by-election. In the Parliament of 1923-
he had the satisfaction of having two sons as fellow member
though they were both defeated in the autumn of 1924. I
MacDonald's Ministry he was secretary of state for home affairs

he was not conspicuous either in administration or in debate.
actively endorsed the policy of his party in 1925–6 in severing
mselves definitely from the Communists who advocated
ned revolution; and he protested strongly, in March 1926,
inst the suggestion made by the Independent Labour party
the formation of a comprehensive international society which
uld include the Communists. (G. E. B.)

IENRI, ROBERT (1865–), American painter, was born
Cincinnati, O., in 1865. In 1886 he entered the Pennsylvania
idemy of the Fine Arts, Philadelphia, Pennsylvania. Pro-
ding to Paris in 1888 he studied at Julien's and the École
Beaux Arts and visited Spain and Italy. Returning to the
ited States he became in 1891 an instructor at the Women's
iool of Design, Philadelphia. In 1896–1900 he was again in
is and exhibited at the Salon. During an extremely active
as a painter, he found time to teach, many of his pupils
aining marked distinction. During the period 1915–23 he
ght at the Art Students' League, New York City, and also
velled extensively. His portraits are distinguished for their
our and vivacity. Of his works, "La Neige" was purchased
899 for the Luxembourg in Paris, and "Girl in White Waist"
er destroyed by fire) was purchased by the Carnegie Insti-
e, Pittsburgh, in 1904. His other works include "Young
man in Black," in the Art Institute, Chicago; "The Spanish
psy," in the Metropolitan Museum, New York City; and
ndian Girl in White Ceremonial Blanket," in the Corcoran
llery, Washington, D.C. He wrote *The Art Spirit* (1923).

IENRY, EDWARD LAMSON (1841–1919), American painter
13.299), died at Ellenville, N.Y., May 9 1919.

IENRY, O. (1862–1910), American short story writer, was
n in Greensboro, N.C., Sept. 11 1862. His real name was
lliam Sydney Porter. Until the age of 15 he attended school,
n for five years served as clerk in his uncle's drug store. The
oor employment threatened his health, and in 1882 he went
a friend's ranch in La Salle co., Texas. Here he spent two
rs, absorbing the colour and robust life of the southwest.
1884 he moved to Austin, Texas, worked as bookkeeper and
n spent four years in the General Land Office.

n 1887 he was married, and about this time he began to send
agraphs and humorous sketches to newspapers. During
1 he was teller in the First National Bank of Austin. In
4 he bought Brann's *Iconoclast*, a satiric weekly, and trans-
med it into an extraordinarily humorous farrago of skit and
lesque, illustrated by himself; the venture was not a success
l in 1895 he joined the staff of the Houston *Post*, writing a
ly column. In 1896 he was indicted on a charge of having
bezzled funds (amounting to about $1,150) from the bank in
stin. The details of this affair have never been cleared up;
re seems no doubt that he was innocent; the bank's affairs
re very slipshod; he may have been shielding some friend; in
case, in a moment of insane impulse he fled from trial and
nt to Honduras. The fatal illness of his wife brought him
k in 1897. While waiting for trial he had the first news of
eptance of some of his stories by important magazines. In
8 he was sentenced to five years in the Ohio Penitentiary.
term was reduced to three years and three months for good
aviour. In prison he seriously settled down to story-writing,
l probably took his famous pseudonym from the name of a
nch pharmacist mentioned in a dictionary of drugs. He left
son in 1901 and went to New York in 1902. In 1903 he con-
cted to do a short-story a week for the New York *World*, at
o each. His first book, *Cabbages and Kings*, was published
904. In 1907 he was married to Miss Sarah Coleman, a boy-
d friend. He died in New York June 5 1910, and was buried
Asheville, North Carolina.

he varied phases of O. Henry's life are reflected in his stories.
e extraordinary productivity of his eight years in New York
ught him rapid fame, though he himself lived secluded and
wn to few. The sale of his books has been enormous and they
e been translated into many languages. For ingenuity of
and racy vividness of narration he has rarely if ever been
passed, but he has been sharply criticised for turning the short story into a "vaudeville stunt." But the genial magic of his fine imagination, antic humour and brilliant narrative skill triumph over the occasional journalism of his method. Subsequent tendencies in literary technique run in an altogether different current, yet O. Henry remains endlessly and enchantingly rereadable. His New York stories are the most famous, but it is probable that some of the southern and western tales, in which there is less strain for glittering effect, are of more lasting value. The tragedy of his own life taught him a chivalrous tenderness for the unlucky; some of the greatest native endowments a writer can have were undeniably his, but his reckless use of them often arouses the trained reader's amazement. Of him, as much as of any modern writer, it can be said that he had "no talent, only genius."

O. Henry's stories were collected in book form under the following titles: *Cabbages and Kings* (1904); *The Four Million* (1906); *The Trimmed Lamp* (1907); *Heart of the West* (1907); *The Gentle Grafter* (1908); *The Voice of the City* (1908); *Roads of Destiny* (1909); *Options* (1909); *Whirligigs* (1910); *Strictly Business* (1910); *Sixes and Sevens* (1911); *Rolling Stones* (1912); and *Waifs and Strays* (1917).

See C. Alphonso Smith, *O. Henry Biography* (1916) and also posthumous collections of sketches and fragments, *e.g.*, *O. Henryana* (1920), *Letters to Lithopolis* (1922), *Postscripts* (1923). (C. My.)

HENRY, VICTOR (1850–1907), French philologist (*see* 13.301), died at Sceaux, near Paris, Feb. 8 1907.

HERBERT, VICTOR (1859–1924), American musical composer, was born in Dublin, Ireland, Feb. 1 1859. His musical education was received in Germany, where he studied under the leading masters. He became principal violoncello player in the Court Orchestra, Stuttgart, also appearing as a soloist on the concert platform in European musical centres. In 1886 he accepted a position as solo violoncellist in the Metropolitan Orchestra, New York City, being subsequently connected with other orchestras as soloist and conductor. In 1894 he was appointed bandmaster of the 22nd. Regt. (N.Y.) Band. In 1898 he became conductor of the Pittsburgh Orchestra. He composed the music for a number of light operas, of which his greatest successes were *Babes in Toyland* (1903), *Mlle. Modiste* (1905), and *The Red Mill* (1906). In 1904 he organised Victor Herbert's New York Orchestra. In 1911 he wrote a grand opera, *Natoma*. More successful, however, was the music which he composed for the photoplay, *The Birth of a Nation*. In his later years he composed much for musical revues. He died in New York City May 26 1924.

HERCEGOVINA: *see* BOSNIA-HERCEGOVINA.

HERCZEG, FERENCZ (1863–), Hungarian novelist and dramatist, was born at Versecz (Viršet) of a family of German extraction. He decided first to adopt a legal career, but soon turned to literature, and after the publication of his first novel his reputation and popularity steadily increased. He became honorary president of the Petöfi Society and a member of the Hungarian Academy. He was several times elected a deputy and through the medium of his review, *Magyar Figyelö*, showed himself to be a staunch supporter of Count Tisza. He was a master of the psychological novel, excelling in the analysis of the feminine mind and in depicting the life of the nobility and of the well-to-do *bourgeois* class. Among the most notable of his historical novels are *Pogányok* (The Pagans) (1902) and *A hét sváb* (The Seven Swabians), while his tragedy *Byzance* (1912) is considered a masterpiece. His novels and plays have been translated into nearly every European language.

HEREDITY (*see* 13.350 and BIOLOGY; CYTOLOGY; EMBRYOLOGY; EVOLUTION; MENDELISM; SEX).—Heredity is the relation of organic continuity between successive generations. It is a genetic or flesh-and-blood relation, effected by the germ-cells which are liberated from parents and develop into offspring. Heredity secures the continuance of a specific organisation; it implies some measure of racial entailment or organic inertia; and yet it does not preclude variability, that is to say the occurrence of marked differences between offspring and their parents.

Even if there had been no evolution there would still be heredity; it would be the genetic relation between successive generations of unprogressive Protists. But there could be no evolution without heredity, for heredity implies the possibility that new departures can be entailed from generation to generation. It is possible that in early times and among simple types there was greater variability than is common nowadays and among more advanced types, and that the evolution of the hereditary relation, *e.g.*, in the advance from asexual to sexual reproduction, put a useful check on the occurrence of variations. But it does not conduce to clearness to say that variation is older than heredity, or to make any antithesis between the two sets of facts. There is a contrast between complete hereditary resemblance in successive generations, which might be compared to inertia in the physical domain, and marked variation, which might be compared to kinetic divergence; but the hereditary relation is such, especially in sexual multiplication, that it allows of novelties or new departures. In short, heredity includes the possibility of variation.

Vehicle of the Inheritance

By inheritance is meant all that the organism is or has to start with in virtue of its hereditary relation to its parents and ancestors. Thus it does not include ante-natal infection, or any imprint impressed on the embryo before birth, or any result of being nurtured in the same environment as the parents. In asexual multiplication the vehicle of the inheritance is obviously the separated off-bud or portion, and it is of interest that a small fragment of a polyp or of a leaf may develop into a perfect organism, always provided that the initial amount be not too minute, that it contain a fair sample of the different kinds of cells in the body, and that it find the appropriate environment. Thus drops of minced sponge, forced through a sieve, may develop into typical forms.

In sexual reproduction the vehicle of the inheritance is obviously in the sex-cells or gametes, but the question arises whether the cytoplasm counts at all as a bearer of hereditary qualities, or whether these are restricted to the chromosomes. That the latter bear many of the hereditary characters is practically proved by Mendelian and micro-dissection experiment, and it is believed by many students that the characters or, more strictly, their initiatives, technically called "factors" or "genes," lie in linear order in each individual chromosome.

The Chromosome Theory.—Some of the arguments for this chromosome theory of inheritance may be briefly stated (*see* Mendelism). (1) There must be significance in the persistence of a particular number of chromosomes for each species, *e.g.*, two for the threadworm of the horse and 48 for man. (2) There is a parallelism in oögenesis and spermatogenesis such that the normal number of chromosomes is reduced to one half by a chance meiotic division, and this conforms to the facts of Mendelian inheritance. (3) In fertilisation there is a restoration of the normal number $(\frac{n}{2}+\frac{n}{2}=n)$, and homologous chromosomes from the two parents unite in couples. The two parents contribute in equal amounts the chromosomal warp and woof of the offspring web, as Van Beneden first showed in his famous paper of 1883. But the full force of this cannot be realised without linking the fertilisation to the antecedent maturation. As McClung puts it:—

> In preparation for the union of the sperm and ovum in fertilisation, by which the duplex chromosome series is established in a new individual, each of these germ-cells reduces its own duplex state to a simplex one by segregating its maternal and paternal members of each pair into different cells by chance distribution in relation to the others.

We may perhaps say that this shuffling of the hereditary cards is one of the opportunities for the origin of fresh permutations and combinations—new departures in short. But there is another suggestion of variability in the fact that in the pairing of chromosomes before maturation-division there is an intimate physical contact (synapsis) in virtue of which there may be interactions and resulting changes. This may be another fountain of variation. (4) In related species there is often a close resemblance in the shape and structure of the chromosomes, and several cases are known in which the numbers of the chromosomes in a gro of species form an arithmetical series, such as multiples of sev in roses. (5) In some cases there is strong evidence to warra associating a particular chromosome with a particular charac in the organism, notably McClung's correlation of the access chromosome with sex (*see* Sex).

An individual chromosome with a recognisable peculiarity shape has sometimes been traced from generation to generati and there is no getting past the large fact that the chromoson are the only individualised elements that perpetuate themsel with precision from generation to generation. (6) In some ca the unit characters or separably hereditary characters of organism form a number of linked groups of unequal numeri value, and with these there is sometimes correlated a similar nu ber of chromosomes, differing proportionally in size. (7) Here a may be noted the growing evidence that there is in the chror somes of the various individuals of a species a definite and c stant linear arrangement of factorial areas or chromomer. Plain then, there are many reasons for regarding the chromosomes the bearers of the hereditary factors.

The Cytoplasm in Inheritance.—On the other hand, the cell unity, and a physiological firm, so that the cytoplasm of ovum may be very important although it is not the bearer of hereditary factors. The experiments of Wilson, Conklin a others show that an egg-cell may contain definitely locali materials that are made use of in the development of partic structures in the embryo. These, therefore, must be compone contributing to the resultant, yet it has to be kept in view th the organisation of the materials in the egg is effected under control of the nucleus and its chromosomes.

Since modern studies of genetics have had very largely to with the newer and more external specific characters, it see premature to shut out the possibility that the vehicle of the ol and fundamental hereditary characters may be in part at le carried by the cytoplasm of the egg-cell, which would not nec sarily mean that they were outside nuclear influence. L maintained that racial characters were cytoplasmic and speci characters chromosomal. Yet, since the quantity of cytopla in the spermatozoön as compared with the ovum is very min on Loeb's view the female parent should count more pred inantly than it does. The question should not be foreclosed.

Fundamental Facts of Heredity

The largest fact is that all kinds of inborn characters, nor or abnormal, "bodily" or "mental," important or trivial, str tural or functional, except complete sterility, may be contin on in the next generation. Even subtle characters, such longevity and fecundity, may form part of the hereditary org isation which is continued on in the lineage of germ-cells. T term "transmitted" should be given up, since it suggests t erroneous idea that the parent makes and endows the germ-c that become the offspring. The parent is more like a trustee.

Continuity of the Germ-Plasm.—The large fact of the p sistence of a general resemblance from generation to generati depends on the continuity of the germ-plasm. What Weism and Galton suggested has been confirmed in detail, that t germ-cells from which offspring develop are continuous alo an unspecialised cell lineage with the fertilised ovum that ga rise to the parent. In many cases the future germ-cells are seg gated at an early stage in development (even at the first clea in Ascaris), but whether they are set apart very early or not, t germ-cells are those cells which have remained unspecialised, approximately the whole inheritance intact, not having sha in body-making and the differentiations therein involved. S saving clauses must be added:—(*a*) for plants where the disti tion between germ-plasm and somatoplasm is only incipient piece of leaf readily developing into a whole plant, flower a all); (*b*) for animals in which the reproductive organs are late being recognisable, *e.g.*, when there is a prolonged asexual la period as in Echinoderms and many of the higher insects; a (*c*) for a few more difficult cases, known experimentally in a higher animals, such as the frog, where body-cells are said to to form germ-cells. But on the whole, the fact of the conity of the germ-plasm is a firm foundation-stone.

erminal Origin of Variations.—It follows theoretically from continuity of the germ-plasm that any novel peculiarity in germ-cells, still more in the fertilised egg-cell, may be coned in the germ-cell lineage of the offspring and thus reappear he next generation, and so on. But what is possible on ral grounds must be proved for particular cases; and it is wn of many new departures of germinal origin that they come ay. The variants breed true. This leaps to the eye when the lty is pathological, but it holds even more true of the normal. olds (*a*) for what may be called "recombination-characters," re the novelty is interpretable as a reshuffling of ancestral ors, yielding, as it were, a new pattern; and (*b*) for mutations h are more distinctively novel—brusque emergences of some ure which was not distinctly represented in the ancestry. s new combinations and mutations agree in being in many s very heritable, whereas it is uncertain that this can ever be of exogenous "modifications," which do not emerge from in but are imprinted from without.

n his prolonged studies of garden snapdragons, Prof. Erwin r finds that there is an abundant occurrence of small mutas (of unexplained germinal origin) which are hereditarily ened and summed up into stable varieties. For this organism ems that the minute mutations count for more than striking e mutations in the establishment of stable cultivated races; it is interesting to note that they correspond closely to the ll variations that Darwin started with as his main form of utionary raw material. In other organisms, however, new binations may count for most, and in others large mutations; indispensable quality is that the germinal new departures are that they can be hereditarily continued.

isappearance of a Germinal Variation.—The non-continuance variation of germinal origin may come about in different s. Its chromosomal representative (a "factor" or "gene") be lost in a maturation-division, *e.g.*, in the formation of the polar body which is given off from the ripening egg-cell and r comes to anything, though it carries off one member of of the chromosome-pairs. Or it is possible that when two ologous chromosomes are coupled in intimate synapsis, an ence passing from one to the other may change the nature factor. When they eventually separate they may have lost ained by "crossing-over" (*see* MENDELISM). Or it may be a factor or gene changes in character just as a microbe somes does, perhaps in response to a subtle environmental ulus.

nother possibility is that the new departure may be fatal or al, or that it may result in a sterile organism. What often pens is that a variation seen in the first filial generation does reappear in the next owing to the absence of some environtal or nurtural influence necessary for its developmental ression. But what is common to all theories of evolution is the hable postulate of *the heritability of variations*. What disuishes the Lamarckian school is the inclusion of somatic odifications" as part of the evolutionary raw material.

nit Characters.—Another foundation stone laid by experital work is the concept of unit characters, features that are tinued on, intact, from generation to generation, without ding or fractioning, either present fully or absent altogether. ther words, unit characters illustrate Mendelian inheritance, the analysis of the organism into a bundle of unit characters for its corollary the germinal representation of these unit racters by a set of factors or genes in the chromosomes of the n-cells. What a "gene" is, we do not know; perhaps a p of molecules in some particular collocation. They are n compared to ferments. The progress of investigation has cated that genes are not immutable, that they may influence another and be influenced by their cellular environment, that may be distributed in linked groups, that several different es may be concerned in the development of one character, that gene may influence several different characters. Finally, the ression that the genes find in development may be dependent on the presence of the appropriate liberating stimulus in the environment.

What has been actually proved is that the organism includes a congeries of unit characters which are hereditarily continued as units, somewhat like the radicals in chemical reactions. It is possible, however, that part of the inheritance consists of a consolidated bloc of fundamental racial characters, which undergo little if any change in the course of generations. It is possible, for instance, that the characters constituting a rabbit a rodent are not hereditarily continued in the same way as the unit characters that constitute the rabbit an Angora.

Galton's Two Laws.—Also important as averaging statistical conclusions are Galton's laws of inheritance. According to the law of ancestral inheritance an inheritance is not merely dual, it is multiple; and the average contributions made by grandparents, great-grandparents and so on, are definite and diminish in a precise ratio according to the remoteness of the ancestor. The two parents between them contribute, on the average, one-half of each inherited faculty, each of them contributing one-quarter of it. The four grandparents contribute between them one-quarter, or each of them one-sixteenth; and so on backwards. This will not apply to cases which illustrate clear-cut Mendelian inheritance; but when characters blend, or have so many factorial units involved that they seem to blend, there may be value in Galton's conclusion that on the average the inheritance of an individual is a mosaic of ancestral contributions. The second law is that of filial regression, or what might be called the tendency to approximate either upwards or downwards to the mean or average of the stock. As Galton said:—

> The more bountifully a parent is gifted by nature, the more rare will be his good fortune if he begets a son who is as richly endowed as himself, and still more so if he has a son who is endowed yet more largely. But the law is even-handed; it levies an equal succession-tax on the transmission of badness as of goodness.

The value of a fine parentage is obvious, but "the ablest of the children of a few gifted pairs is not likely to be as gifted as the ablest of all the children of a great many mediocre pairs." On the other hand, two gifted members of a poor stock may be personally equivalent to two ordinary members of a good stock, but the children of the former will tend to regress; those of the latter will not. To take Prof. Karl Pearson's illustration, the mean height of the sons of, say, 1,000 six-ft. fathers will be 70·8 in.; the mean height of the sons of 1,000 66-in. fathers will be 68·3 in., again a regression toward the mean of the general population. "The father with a great excess of the character contributes sons with an excess, but a less excess of it; the father with a great defect of the character contributes sons with a defect, but less defect of it. The general result is a sensible stability of type and variation from generation to generation." Galton's laws are statistical, not physiological; they require correction in regard to characters which are subject to persistent keen selection, either natural, sexual or artificial; they will not apply to sharply defined "unit characters" which do not blend. The data which Galton utilised were chiefly the records of family faculties, as to stature, eye-colour, temper, artistic ability and so on, but they were to some extent supplemented by measurements in Galton's anthropometric laboratory, and by observations on plants and animals. The most reliable data were those relating to stature, and they are open to the criticism that they included indiscriminately what is due to somatic modification and what is due to germinal constitution. In the view of many biologists this greatly lessens the value of Galton's laws.

The Past in the Present.—Looked at broadly, the facts of heredity illustrate the way in which the past lives on in the organism, active and acting. The inheritance includes many items of different degrees of antiquity, some very ancient. These have for the most part useful inertia, but there is often a striking persistence of anachronisms, both of structure and function. There is a remarkable staying power in characters that illustrate Mendelian inheritance, whether for good or ill. There is an indubitable recapitulation of phylogeny in ontogeny, especially in organogenesis; and it is the continuity of the germ-plasm that makes all this possible. For the same reason, there is a conservation of advantageous tentatives in so far as these are the outcome of germinal variations. In short, heredity and development show us the organism as a historic being, and moreover as one that enregisters the ages that are past.

HEREDITY AND DEVELOPMENT

The most elusive of problems concerning heredity is the most familiar one: how does the hereditary material in the chromosomes and in the cytoplasm develop into the organism. There is a hereditary preformation of some sort in the chromosomes with their genes, and to this the cytoplasm—with so little in the way of organisation to start with—responds in a perfectly precise and controlled way; but physiological embryology, though rapidly progressive, is still a long way from an understanding of what occurs. As to the mind of Aristotle, so to the biologists of to-day, development remains a central secret (*see* EMBRYOLOGY).

Transmissibility of Somatic Modifications.—Some advance has been made in regard to the long-standing problem often designated "the inheritance of acquired characters." The history of the discussion shows that Weismann and Spencer, who took opposite sides, meant by "acquired characters" only one kind of thing—those somatic changes that are directly due to some peculiarity in use and disuse, nutrition, or environmental influence, and which persist in the individual, for some time at least, after the inducing conditions have ceased to operate. It is irrelevant and illegitimate to maintain that "acquired characters" should mean something else. As long as the Weismann-Spencer argument continues, it is necessary to keep to the original use of the terms. That there are corollaries must be allowed, such as (*a*) the transmissibility of the secondary effects of modifications, or (*b*) the possibility of a specific influence being impressed simultaneously on soma and on germ-cells. But the main question is a precise one: Can a modification, as defined, affect the germ-cells in such a specific or representative way that the offspring will, through its inheritance, exhibit, even in a slight degree, the modification which the parent or parents acquired? May there come about in the germ-cells a heritable registration of some specific modification imprinted on the parental body?

To get a clear issue, as regards the precise problem, there should be an avoidance of (*a*) data referring to Unicellulars, where there is only a beginning of the contrast between somatoplasm and germ-plasm; (*b*) data which involve the possibility that the germ-cells may be influenced along with the body by some penetrating toxin or hormone or radiation or the like, connected with the imprinting of the original modification and (*c*) data relating to viviparous organisms, *e.g.*, mammals and seed-bearing plants, where it may be that a modification of the parent, such as acquired immunity or acquired evergreenness, comes to be shared by the offspring because of the intimacy of the antenatal partnership. If this occurred it would have in the first generation the same practical result as if there had been a specific repercussion on the germ-cells, but it would not be a convincing case, unless it held good when the modification was exhibited by the male parent only. Both for placental mammals and for seed-bearing plants it is easy to conceive of specific metabolic products or metabolites passing from the mother to the offspring before separation occurs.

Need for Data from at Least Three Generations.—When organisms are transferred to novel surroundings or conditions of life, such as those of a colder climate, it often happens that an advantageous modification is induced, such as a longer coat of hair in a mammal; and it may be that this modification appears in increased expression in the next generation. But this would prove nothing more than modifiability, for the second generation was exposed for a longer time than the first to the modifying influence. But if the character in the third generation was larger in amount than in the second, an interesting fact would be established.

Changed Environment.—Yet the crucial cases must be those where the offspring of modified parents develop in an environment which does not include the modifying factor which effec the change in the parental soma. Thus in Prof. W. E. Ag model experiments, specimens of the entomostracan Simocep lus that were reared in water with certain nutritive peculiarit showed a distinctive reversal of their two shell-valves doubt due to the altered metabolism. They were reared to matur and then transferred to ordinary water where they libera their ova. These developed into individuals which showed modificational peculiarity that their parents had acquired.

Later on, however, when the parents again liberated ova, abnormal effect was seen only to a very slight degree, and i third brood (not generation) it had dwindled away. This v instructive case suggests that the abnormal nurture had result not in any disturbance of the inheritance, but in the formati of some peculiar non-living metabolite, which was included in cytoplasm of the egg, passed passively into the body which veloped from the egg, and there produced on the body of offspring the same effect as it originally produced on the bo of the parent which acquired the character in question. As supplies of the metabolite were exhausted, its influence dwind in the second brood, and disappeared in the third. This ill trated the importance of changing the environment in su experiments.

Alcoholised Animals.—Many experiments have been made the effect of alcohol (usually inhaled fumes) on animals, the results are not altogether in accordance. Thus while th may be no observable deterioration in the treated guinea-pi there is clear evidence of this in their untreated offspring. On other hand, Prof. Raymond Pearl found that after alcohol tre ment his fowls produced offspring which were superior in marked degree to those produced by non-treated controls. Pear interpretation of this is that the alcoholic treatment eliminat all the inferior germ-cells in the ovary of the fowls, leaving coast clear for the superior ones to produce the next generati Of the reality of this process of germinal selection there is so histological evidence.

In Dr. F. B. Hansom's experiments on white rats there was observable effect on to the end of the second generation. Th that were subjected to inhalations of alcohol were in no different from their relatives that breathed normally. Moreov the treated offspring of the treated parents were indistingui able from their first cousins, the untreated offspring of untreat parents. But in the third generation, a change occurred. At age of 20 days, before any individual treatment, the members the treated lineage showed themselves inferior in body weig body length and tail length, when compared with their count parts on the untreated lineage. When alcohol-inhalation beg the difference became more marked, as if the animals were sponding to the abnormal condition with a new susceptibility. reached a maximum of nearly 10 times the probable error.

Now the natural inference at this stage in the experim would have been that the influence of two previous generatio of alcoholic inhalation was beginning to make itself felt. And the effects were observable before individual treatment beg the inheritance of the generally deteriorative influence of alco might have been held as proved. But the remarkable fact that the fourth generation showed a marked improveme "The treated side of this generation for the first half of growth curve is back to the fold with the first two generatio Later there is some response to the treatment and a conseque dropping off in the curve." This remarkable result suggests th some process of germinal selection may have been at work. elimination of inferior germ-cells; but it also suggests caution.

Prof. Charles R. Stockard's experiments on alcoholis guinea-pigs, continued for 13 years, showed no deterioration the treated parents up to seven years, which is a great age these animals. But the deteriorative influence on the immedia offspring and on later descendants was shown in debility, sho life and arrested development. Yet there was no evidence of transmission of any particular character. The probability is th the alcohol, saturating through the body of the parent, poison the germ-cells and deteriorated the constitution of the offspri

general way. But here, again, there was the remarkable
omenon, that after three generations of treating, there was a
ed improvement. The members of the fourth filial genera-
of treated "pigs" were actually superior in vitality to the con-
. This may have been due to the elimination of the weak-
and defectives, perhaps also to a sifting out of germ-cells.
her Striking Experiments.—Dr. Bentley and Dr. Griffith
d that some of the progeny of rats rotated for a long time
round-about showed a high degree of disequilibration and
ioration, but it is possible, as Dr. Detlefsen has suggested,
some microbic infection (causing inflammation of the
ory labyrinth) may have complicated the issue.
inting towards a transmission of specific modifications are
ntricate experiments of Prof. M. F. Guyer and Dr. E. A.
h on the continuance of artificially induced eye-defects in
its. Very suggestive in the same direction are Dürken's
riments on the colour of the pupae of the common white
erfly, where there seemed to be a hereditary effect of artificial
ination. To many biologists it seems that there is unques-
ible validity in the numerous experiments of Kammerer
h point in several cases to the hereditary continuance of a
ntal modification. Thus when the young of the spotted
nander are kept on black backgrounds the black patches on
skin increase in size, while if they be kept on yellow back-
nds the yellow patches increase. This change towards
ter blackness or towards greater yellowness was found to
o a considerable extent heritable, for the offspring of the
ified parents showed a similar change in a marked degree.
ed they began in a colour phase nearly, though not quite, as
nced as that at which their parents left off.
ıus it would be possible to continue citing cases first on one
and then on the other, on both sides open to detailed crit-
. But the moral seems to be that this long-discussed ques-
cannot even now be regarded as closed. There must be a
nt accumulation of more data, more rigorously tested or
ied; and the question at issue is of such importance as to
d any hurry to a conclusion.

NATURE AND NURTURE

ider than the question of the transmissibility of somatic
ifications is that of the relation between hereditary nature
environing nurture. The difference between the two com-
entary factors is referred to in Prospero's description of Cal-
as "a devil, a born devil, on whose nature nurture will never
." It is evident, however, that the two factors should not
pposed as if they were antithetic, for while no amount of
ure will make a bad inheritance good, there can be no de-
pment at all without a minimum of nurture, and on the
rosity of the nurture the development of the heritable char-
r will in some measure depend.
t the beginning of the individual life the implicit organism
the inheritance are one and the same, but by subjecting germ-
and embryos of the same origin to different "nurture"
ctional, nutritional and environmental) it can be shown
there are different reactions according to the developmental
litions. The young proteus kept in darkness remains un-
ented, but its neighbour reared in a well-lighted laboratory
mes dark. A Chinese primrose (*Primula sinensis*) reared at
C. will have white flowers (var. *alba*), but its neighbour, or,
on, itself brought under the influence of higher temperature
C.), shade and moisture, will have red flowers (var. *rubra*).
rding to diet a tadpole may become large and poorly dif-
ntiated, or small and well-differentiated. There are scores
ch cases.
ggs, embryos, larvae and so on, of the same genetic origin,
develop very differently according to the conditions of life,
conversely, differently endowed young organisms may de-
p very differently though reared in nurtural conditions which
precisely the same, as we see when good seed and poor seed
sown in the same plot. Therefore, it is legitimate to dis-
uish the hereditary factor in development from the func-
l or the environmental factor. As we have said, an antithesis between hereditary "Nature" (Galton's "natural inheritance") and extrinsic "Nurture" (all manner of environs mental, nutritional and functional influences) is illegitimate, since both are necessary components of a resultant, as clay and heat to brick, or water and wind to wave; yet for the reasons given, it is permissible and useful to discriminate between the two aspects. It is sound biology to say of some particular peculiarity in an organism that it is due (*a*) to the loss of some item in the natural or germ-plasmic inheritance, or (*b*) to some nurtural defect which inhibited the developmental expression of items that were certainly present in the inheritance, as subsequent breeding shows. Similarly, on the positive side, it makes a difference if the development organism has received factors for a particular character from both parents; and it makes a difference if the nurture is unusually stimulating as regards the expression of a particular character.

ENVIRONMENT AND INHERITANCE

Some biologists are so sensitive to the abstractness of all the biological pigeon-holing, that they have seriously proposed to include the normal appropriate environment of the young organism as part of its "heredity," for, as they say, what does the inheritance amount to if the appropriate environment is wanting—a bundle of cheques but no bank. Perhaps, however, this is unnecessarily pedantic, after it has been agreed that these various "aspects" are devices for scientific analysis. Every living creature must have its surroundings; every embryo must have its nurture; function is only the unending sequence of actions and reactions between organism and the environment. All this may be granted, and yet it is useful and necessary to try to distinguish in development the respective influences of "nature" and "nurture"—including in the latter three sets of conditions: environmental, nutritional and functional.

Up to a certain point the fertilised ovum of a mammal may be induced to develop outside the mother, or an isolated neuron of a chick-embryo will grow in a droplet under the microscope, thus illustrating the hereditary inertia. Yet if the larval proteus be reared under red light in the laboratory, the minute primordium of the eye, which in the normal cave-environment remains arrested and buried, increases in size and in the differentiation of optic structures. It may actually grow to meet the skin and become a seeing eye, thus illustrating the potency of altered environment as a liberating stimulus. No doubt there are nurtural limits outside which normal development will not occur, but the majority of organisms in natural conditions find this minimum environment at least. This will be agreed to by all. What is more interesting is the question how far changes in the nurture, such as are of frequent occurrence in natural conditions, will serve as inhibitants and stimulants. The same kind of sponge may grow into a dwarf that lives in a hole excavated in an oyster-shell, or in conditions of greater freedom it may grow into a large vase. If a bonellia larva rests for a while on the proboscis of the adult and absorbs inhibitant nutritive material from the skin, it develops into a pygmy male; but if, after the free-swimming stage, it settles down in the mud, and not on a proboscis, it develops into a large and vigorous female.

Function and Heredity.—Along with the environmental and nutritional influences, those of active functioning must be included, though it is of course evident that the activity or inactivity, the restlessness or sluggishness of the developing organism is an expression of its particular inheritance. The free-swimming tunicate larva has in ordinary cases no alternative to becoming sedentary; the collapse is an expression of the inheritance. Yet in some cases the individuals of a family, clutch or litter, vary demonstrably in their heritable constitutional bias in the direction of greater or less activity—perhaps the commonest of all variations—and thus there arise differences in development which afford raw material for natural selection. Especially in relatively less stereotyped forms, *e.g.*, in fishes compared with mammals, the importance of active functioning in the course of development is momentous, for it is on the active functioning that the detailed expression of hereditary characters depends. A vicious circle must be avoided, but not so timorously that we thereby miss a great truth.

The degree of development, *i.e.*, the expression of hereditary characters, depends in part on surroundings and food, but it also depends on the activity of the young creature such as the fish-larva, and on the action of part on part. The degree of this activity depends largely on the inherited constitution (and partly on food and environment), therefore we are not suggesting that it is a separate entity or anything of that sort. We are only emphasising a commonplace that is often missed: The differentiation of characters in development depends in part on the functioning of the young organism, and changes in the intensity of the functioning will result in changes in the evocation of structure. The changes in intensity of functioning may be of the nature of germinal variations, or they may be reactions to environmental stimulus. If the environmental stimulus should become constant, a modificational specific character might arise.

It is possible that many constant characters of a species are really of the nature of constantly re-impressed modifications. As Dr. Harry M. Kyle puts it: "The constancy of a species depends upon the persistence of a normal environment." From this point of view we get a useful new light on heredity. To some extent, especially in the lower grades of life, the inherited material may be moulded this way or that way if the nurture is changeful, or it may find a deceptively stereotyped expression when the nurture is very constant from generation to generation. Between inheritance and environment comes the activity of the individual. Dr. Kyle's *Biology of Fishes* (1926) may be cited for its many illustrations of this important thesis.

HEREDITY AND DISEASE

For biological purposes a disease may be defined as a deteriorative process which tends to disintegrate the unity of the organism. The associated pathological changes cannot be separated off in any hard and fast way from ordinary vital changes, and what is a disease in one animal may be normalised in another type—let us think of the growth and decay of the stag's antlers. Yet disease implies that certain processes of metabolism have got out of place, out of time and out of tune.

For biological rather than medical purposes, again, we may distinguish four kinds of disease:—(1) There are environmental diseases, such as debilities due to lack of light or to deficiency in certain constituents of the food. Perhaps rickets may serve as an example. (2) There are functional diseases, which are due to overwork, lack of exercise or to some deteriorative factor in the occupation. Some kinds of heart strain, certain forms of obesity and lead poisoning may serve as examples. (3) There are the familiar microbic and parasitic diseases, due to the poisonings, lesions, blockings and so forth that are produced by intruding organisms of a hostile character; as in plague, tuberculosis, sleeping-sickness, malaria, and the disturbance brought about by hookworm, bilharzia, and other non-microbic invaders of man's body. It has to be recognised that part of what is, for practical purposes, called the disease in such cases, is the organism's defensive or even offensive reaction to the intruder, as in the phagocytosis associated with inflammation. (4) On a different plane are organic or constitutional diseases, which are due to some very early germinal or embryonic disturbance or defect.

A deteriorative peculiarity in the metabolism associated with excretion may find expression in kidney disease; or some defect in the inheritance may express itself later in one of the forms of epilepsy; or some inborn and at present inexplicable lack of balance in the functioning of the endocrinal glands may lead to one of the forms of diabetes. Apart from parasites, there is almost no disease in wild nature, where it is speedily nipped in the bud if it shows itself; in mankind and in his stock, where selection for health is less searching and insistent, where the struggle for existence is rarely with the gloves off, and where the conditions of life are often very artificial, disease is rife. In the case of organic or constitutional diseases, the organism starts with an inherited handicap, to which ill-advised nurture may add. In the other kinds of disease, the immediate cause is in great extrinsic, though less so in occupational diseases, but the extri influence may have its deteriorative effect increased by hereditary predisposition on the organism's part, which has to fight a battle with two fronts.

A few general statements may be made in regard to here and disease. There is no proof that modification-diseases vironmental, occupational or habitudinal) can be transmi from parent to offspring, but they may bring about a gen weakening of the germ-plasm, and they may influence the prejudicially through the mother. Microbic diseases are transmissible, though a susceptibility to them may be, though very early—ante-natal—infection may bring abou semblance of heritability. As a disease is a process, there are instances of hereditary disease in the strict sense; but there many instances of definite heritable taints, that is to say, stitutional predispositions or susceptibilities that render organism peculiarly liable to deteriorative influences in surro ings, in nutrition and in functioning, or to the assaults o truding microbes. If a hereditary taint is a recessive Mende character it will be masked by the corresponding domi character, that is by normality. Thus it will not find indivi expression, though it remains part of the inheritance. It is sible that a pathological feature, *e.g.*, a nervous disturbance, find expression earlier and earlier in development, until it comes fatal at a very early stage (Sir F. W. Mott's "la anticipation").

HEREDITY AND CONSANGUINITY

The older view that consanguinity is necessarily of itself teriorative has not been confirmed experimentally. Lea man's case apart, where psychological and social considera complicate the issue, there is abundant evidence that the breeding or endogamy of healthy stock may go far without deteriorative results. In the early chapters of the establishm of some of the famous stocks of domesticated animals there been very close inbreeding. If there is a well-defined tain some sort, it is plain that inbreeding will increase it if exhibited by both the parents. If a given character exhi Mendelian inheritance, the result of inbreeding must alwa the isolation of homozygous types—pure as regards the char in question. It matters not whether the character is adva geous or detrimental, except that in the latter case it may cross the limit of viability. If we suppose that a herd incl a percentage of individuals with a recessive taint, this will to become less conspicuous in conditions of outbreeding or amy, since the offspring of recessive tainted and domin normal will appear normal.

But in conditions of inbreeding or endogamy, the taint become more and more conspicuous, since the chances of tainted parents coming together will be greater, and the offsp will be homozygous recessives. Thus there will come abou isolation of a homozygous tainted type (or, in more com cases, types), and the rapidity of the isolation will be in pro tion to the intensity of the inbreeding. When the taints inte the breeder practically he fixes his attention on them, and in the past, consanguinity has been blamed for causing wha merely discloses. It should be noted that there may be rem able combinations of deteriorative recessive characters, pr ously hidden by their dominant allelomorphs, and that may be a general reduction in the vigour of the herd as diffuse. We cannot wonder, then, that inbreeding has come have a bad name. But the facts all point to the conclusion what the inbreeding itself does is to expose undesirable cha ters that already existed, but have been masked by their inants. It follows that inbreeding can be used as a sieve for radical improvement of a stock, since the exposed abnormali deficiencies and undesirabilities can be artificially eliminated

A subsequent outbreeding with good stock will re-invigo the purified inbred stock, for there will be a pooling of good ities comparable to the previous accentuation of bad Moreover, there may be a useful outcrop of fresh variations,

often follows the introduction of fresh blood. It may be
itely concluded, then, that inbreeding is not injurious be-
e of the consanguinity, and that if the breeder understands
: is happening, it may be made highly beneficial. The
rimental evidence will be found conveniently in *Inbreeding*
Outbreeding, by E. M. East and D. F. Jones (1919). There
is to be no biological reason for objecting to the marriage of
thoroughly healthy cousins; and it would appear that the
nation of periods of inbreeding and outbreeding has counted
nuch in the history of human stocks and tribes and races.

nclusion.—One cannot turn from this survey without
ring to the fatalistic impression that the study of heredity
ot to produce: the hand of the past has such a heavy grip.
'the other side of heredity" must also be emphasised—the
stence of the stable, the conservation of advantageous qual-
the continual emergence of the new, the influence of nurture
termining the degree of development to which the hereditary
re attains, and, in man's case, the dominant importance of
xtra-organismal or social heritage. A man cannot alter the
ber of his separate hereditary "talents," to use the phrase-
y of the immortal parable, but he can trade with what he has,
he is thus not only born, but made.

ERKOMER, SIR HUBERT VON (1849–1914), British painter
13.364), died at Budleigh Salterton, Devon, March 31 1914.

ERMANT, ABEL (1862–), French author and dramatist,
born in Paris Feb. 3 1862. A brilliant wit and an exquisite
ist, he consistently devoted his abundant talents to des-
ing the lighter side of life. His most characteristic works
those grouped under the general title, *Mémoires pour servir*
istoire de la société (1905), wherein, with unfaltering gaiety
a humour saved only by the delicacy of its expression from
earing scabrous, he mocks the aristocracy and wealthy
rgeoisie of France. He excels, too, in long series of amusing
ogues. *Le Caravansérail* (1917), a study of rich foreigners
ged into the cosmopolitan circles of Paris, is perhaps his
-known work, but the series of *Scènes de la vie des cours et des*
assades, which includes *La carrière* (1894) and *Le sceptre*,
o), no less pungently portrays the complications of diplo-
y in a dignified Central European court. Among his plays
be noted *La meute* (1896), a comedy of parasites, and
ie, ou la curieuse d'amour (1900), which with infinite grace
lays the reactions of a light-headed woman to the successive
ses of revolutionary and imperial France.

HERRICK, ROBERT (1868–), American author, was born at Cambridge, Mass., April 26 1868. He was educated at the Cambridge Latin School and at Harvard University where he graduated in 1890. He was appointed instructor in rhetoric at the Massachusetts Institute of Technology in 1890 and three years later accepted a similar position at the University of Chicago, where he became professor of English in 1905. His novels and short stories deal with the complicated problems of modern life in realistic fashion. They include *The Man Who Wins* (1895); *The Gospel of Freedom* (1898); *The Web of Life* (1900); *The Real World* (1901); *The Common Lot* (1904); *The Memoirs of an American Citizen* (1905); *The Healer* (1911); *One Woman's Life* (1913); *The Conscript Mother* (1916); *Homely Lilla* (1923); *Waste* (1924); *Wanderings* (1924): and *Chimes* (1926).

HERRIOT, EDOUARD (1872–), French politician, was born at Troyes, in Champagne, July 5 1872, the son of an officer. He was sent first to the Lycée of La Roche-sur-Yon, and afterwards to that of Louis-le-Grand, which bore the reputation of being the best school in France. He then entered the École Normale Supérieure, which included many eminent teachers such as Brunetière and Gaston Boissier, both of whom were men of authority and unquestioned reputation. Here he remained working assiduously for several years, and while delighting in the pursuit of learning thoroughly enjoyed the interchange of ideas with his fellow-students, on whom he left an unforgettable impression. In 1894 he graduated with high honours. Whilst undergoing his military service at Nancy, his favourite relaxation was the study of Greek literature. His book *Philon le Juif* (1897) was crowned by the Académie Française.

Having been appointed a professor at the Lycée of Nantes, he was entrusted the following year first with the Chair of rhetoric, and then of higher rhetoric at the Lycée of Lyon. He imparted to his pupils not merely the principles of knowledge but also the love of it for its own sake; a scholar of great refinement, he possessed the gift of stimulating others, and his discourses were so lucid and attractive that all who heard them were captivated. On relinquishing his Chair he became a popular lecturer, as well as journalist and propagandist, and his book, *Madame Récamier et ses Amis* (1905), achieved widespread popularity. His *Précis de l'histoire des lettres françaises* (1905) shows that his literary criticism was based on a minute study of the text.

A man of M. Herriot's wide sympathy could not fail to be drawn into public life. In May 1904 he was made a municipal councillor and deputy Mayor of Lyons and the following year became Mayor. Thenceforward, with the exception of three months, he guided the destinies of Lyons; for at each successive election of the Municipal Council he resumed office. In 1910 he became a member of the conseil général and in 1912 senator for the department of the Rhône. From Dec. 1916 to March 1917 he occupied the post of Minister of Public Works, Transport and Supplies in the Cabinet of M. Briand. During this time he inaugurated a policy of restriction which enabled France to economise her resources, while at the same time lessening the drain on them caused by the World War, and enabling her to gain a more speedy victory. Having to a large extent solved the problem of supplies, he proceeded to bring order into the transport service. Stations, railway lines and ports were cleared and an efficient service was maintained.

M. Herriot now felt that by entering the Chamber, he would be better able to carry out his cherished ideas. He therefore renounced his office as senator, and was elected in Nov. 1919 deputy for the Rhône department. He was then appointed a member of the Finance Commission and reporter-general of the Budget of Public Instruction. The Radical party now chose him as their leader, and as a defender of the principles of democracy he soon reached the front rank of French statesmen. As an orator he showed subtlety and versatility, combined with a vivid imagination, while his delivery was pleasing and impressive. At times he was a man of the people, then at other times his eloquence was that of the scholar soaring into metaphysics. Both in speaking as well as writing M. Herriot always approached his subject from the loftiest standpoint—the result of his wide knowledge, culture and absolute integrity. His chief qualities might be summed up in three words: logic, wisdom and conviction; and it was the combination of these which enabled him to draw up a formula for an experimental policy.

Even before hostilities had ceased, M. Herriot turned his attention to post-War problems. By his actions as well as in the Press he insisted on the necessity for the reconstruction and economic development of his country. In 1916, at the moment when the victory of Jan. seemed imminent, he organised the Lyons Fair, that magnificent international market which not only promoted the economic interests of the town and district, but at the same time contributed in a remarkable degree to national prosperity. This exhibition, though it cost the inhabitants of Lyons nothing, possessed a great palace to which each successive year new pavilions were added. That it proved a formidable rival to the Leipzig Fair, and had an ever-increasing success, was a striking testimony to M. Herriot's robust optimism. In 1917 he published *Agir*, a book which at a time when the fate of France was so uncertain, bore the character of an unflinching act of faith; for in it M. Herriot maintained that the culture and civilisation of France were too deep-rooted and too strong to be overcome. This gospel of action soon inspired the faint-hearted with fresh hope.

After the victory, M. Herriot brought out a work in two volumes, *Créer* (1919), dedicated to the youth of France. It contained his programme of reconstruction, and gave his compatriots a fine example of resolution, fearlessness and patriotism. A similar example emerged from his visits to Russia, the U.S.A. and Canada. He was soon confronted with an even harder task than before, for as head of the Radical party the eyes of all French democrats were turned towards him. It was he who inspired the opposition and acted as its mouthpiece, yet he remained faithful to his original ideals, and even in the heat of conflict never allowed himself to forget that one day the responsibility of office might fall to him again. After the elections of May 1924 he became Premier and Minister of Foreign Affairs and immediately set to work to reform the policy of France. During the London conferences, in the application of the Dawes plan and finally over the Geneva protocol, he displayed a rare combination of idealism and common sense, and outlined those great aims, in pursuit of which the nations of the world should unite to avoid war. By these efforts he gained the confidence of all men of good will, not only in Europe but over the whole world. Germany in consequence offered to draw up a security pact destined to be signed eight months later at Locarno.

This admirable achievement, however, by no means disarmed M. Herriot's adversaries. The financial problems which he had to face were the occasion of innumerable attacks upon him and finally a hostile vote of the Senate obliged him to resign in April 1925. A few days later, he was elected president of the Assembly by the deputies who desired to testify to the courage, zeal for work and talents of the leader of the Left. The office of President gained an added lustre through the tact, good humour and timely exercise of his authority shown by M. Herriot, and everyone cheerfully submitted to his arbitration. During the many critical moments in the history of contemporary French politics, M. Herriot, with his idealism, practical wisdom and patriotism, proved a guiding light. He devoted his few leisure hours to writing *Dans la forêt Normande*, a book worthy not only of a great writer, but also of a philosopher. (L. Ri.)

HERTLING, GEORG, Count von (1843–1919), German statesman, was born in Darmstadt Aug. 31 1843. In 1882 he was appointed professor of philosophy in the University of Munich. From 1875 to 1890 and again from 1893 to 1912 he was a member of the Reichstag, from 1909 being for a short time the leader of the Centre (Catholic) party. In 1912 he was appointed president of the Bavarian ministry and minister for foreign affairs, and in 1914 was elevated to the rank of count by King Ludwig III. On Nov. 1 1917 he accepted the chancellorship of the Reich, which he had refused in July of that year; and for 12 months he strove against the encroachments of the military authorities upon the political affairs of the Empire. The failure of the German offensives in 1918 finally destroyed his hop being able to negotiate with the Allies on anything like e terms and feeling at last unequal to the struggle against introduction of real parliamentary Government, he resi Sept. 30 1918, and returned to his home at Ruhpolding in U Bavaria, where he died Jan. 4 1919. His reminiscences published in 1919 under the title of *Erinnerungen aus mei Leben*. See also Karl Hertling, *Ein Jahr in der Reichska* (1919).

HERTZ, JOSEPH HERMAN (1872–), Chief Rabbi of United Hebrew Congregations of the British Empire, was in Rebrin, Czechoslovakia, Sept. 25 1872. Emigrating to Am as a child, he was educated at New York City College, Colu University, where he took the degree of Ph.D., and the Je Theological Seminary of America. He was a Rabbi in Johan burg, South Africa, from 1898 to 1911 and, during the Boer was expelled by President Kruger for pro-British sympat and for advocating the removal of religious disabilities from and Catholics in the South African Republic. From 1906 to he was professor of philosophy at Transvaal University Col Dr. Hertz was elected to the Chief Rabbinate in succession to Hermann Adler, in 1913. In 1920–1 he undertook an exte pastoral tour, visiting the Jewish communities in South Af Australia, New Zealand and Canada. He became Preside Jews' College, London, in 1914. In 1925 he was made on the board of governors of the University of Jerusalem and ch man of the administrative board of its institute of Jewish stu He also became vice-president of the Anglo-Jewish Associat the London Hospital and the League of Nations Union. Am other Jewish writings, he published an anthology *A Boo Jewish Thoughts* (1917), of which 17 editions had appeare 1926. He was a member of the original board of translato the Jewish Bible Version, 1896–1903.

HERTZOG, JAMES BARRY MUNNIK (1866–), S African politician, was born at Wellington, Cape Colony, A 3 1866. Educated at Victoria College, Stellenbosch and sterdam University, he became a judge in the Orange Free S in 1895, and served through the South African War of 1899 He voted against peace at Vereeniging and, frankly hostil the British connection, he helped to keep alive this anti-Br feeling after the War. On the grant of responsible govern in 1907, he became attorney general and minister of educa in Fischer's ministry, and forthwith began to undo the wor the Crown Colony Administration. He tried to force upon schools a system of compulsory bi-lingualism—Dutch English—which was crude and impracticable. The direct education resigned, and one of the three inspectors, dismi without enquiry, won an action for libel against Hertzog *cause célèbre*.

In the first Union Cabinet, in 1910, Hertzog became mini of justice under Botha, but his attitude made the position tenable. Botha resigned in 1912, took office again, reconstru his Cabinet and left Hertzog out. The latter then forme opposition party with complete independence of Britain as goal, and his perfervid nationalism gained him much influ among the old Republican Boers. After the World War he tinued his separatist policy but finally formed a "pact" the Labour party. In 1924 this Coalition came to power Hertzog as prime minister, whereupon he disclaimed any tical application of his republican policy. In 1925 he bro the native question into the forefront of the political arena, rendering a great service to the future of the country owin the increasing gravity of the problem in its relation to the tinued supremacy of a comparatively small white populati (H. Gn.

HERVIEU, PAUL (1857–1915), French dramatist and no (*see* 13.405), produced his last play, *Le Destin est maître*, in 1 He died in Paris Oct. 25 1915. See A. Binet, *Portrait psy logique de Paul Hervieu* (1914); H. Burckhardt, *Studien zu Hervieu* (1917).

HEWART, GORDON HEWART, 1st Baron (1870– British lawyer, was born Jan. 7 1870 at Bury, Lancash

ng graduated as a scholar of University College, Oxford, he
alled to the Bar in 1902 and practised on the northern cir-
After an unsuccessful contest in Northwest Manchester
12, in which year he took silk, he was elected as a Liberal
eicester in 1913, and after the rearrangement of constitu-
s in 1918 represented the eastern division of that city from
till his retirement from Parliament. In Dec. 1916 he was
inted solicitor-general in Mr. Lloyd George's Coalition
rnment. Having afforded useful support to the adminis-
on by his talents as a debater, he was made attorney-general
n. 1919, and was admitted to the Cabinet in 1921. He gave
rial assistance in the conduct of reconstructive legislation,
took an active part in the final phase of the negotiations
the Sinn Feiners, being one of the signatories of the so-called
Treaty. He acted as president of the War Compensation
t from 1922. He had been knighted in 1916; on Jan. 16
he was sworn of the privy council, and on March 24 1922
appointed lord chief justice, being at the same time created
n Hewart of Bury.

EWLETT, MAURICE HENRY (1861–1923), British man of
rs (*see* 13.417). The best of his later works are *Mrs. Lance-*
1912); *Bendish* (1913); and *Mainwaring* (1921). His main
est, however, was directed from fiction to verse. *The Song*
e Plow (1916) has been recognised as one of the most con-
able narrative poems of the century; it describes the for-
s of the English farm labourer from the earliest times to
World War, and though occasionally the imaginative beauty
bscured by necessarily prosaic detail, contains numerous
ages of a fine masculine vigour. *The Village Wife's Lament*
8) is a more uniform and but slightly inferior poem. In
of Proserpine (1913), Hewlett attempted, with some success,
int in delicate prose at the mystical semblances of nature,
his essays, *In a Green Shade* (1920), were warmly received.
translations and imitations of the sagas, including *Thorgils*
readholt (1917), also deserve mention. The popularity of his
er fiction concealed from many of his contemporaries the
ngth and originality of his later work. He died at Broad-
ke, near Salisbury, June 15 1923.

EYSE, PAUL JOHANN LUDWIG (1830–1914), German
elist, dramatist and poet (*see* 13.438), received the Nobel
e for literature in 1910. His later works include *Helldunkles*
n (1909); *Italienische Volksmärchen* (1914) and *Letzte Novel-*
(1914). He died at Munich April 2 1914. Several volumes
is letters have appeared (1916, 1917, 1919). See also H. Raff,
l Heyse (1910).

IBBEN, JOHN GRIER (1861–), American educationist,
born at Peoria, Ill., April 19 1861. He graduated from
ceton University in 1882; was a student at Princeton Theo-
cal Seminary from 1883 to 1886; and later studied at Berlin.
1887 he was ordained a minister in the Presbyterian Church
was a pastor for four years at Chambersburg, Pennsylvania.
1891 he returned to Princeton, where he taught logic as an
ructor (receiving the degree of Ph.D. in 1893), assistant pro-
or, and from 1907 professor. In 1912 he succeeded Woodrow
son as president of the university.

is works include *Inductive Logic* (1896); *The Problems of Phi-*
phy (1898); *Hegel's Logic* (1902); *Logic Deductive and Inductive*
5); *The Philosophy of the Enlightenment* (1910, contributed to the
chs of Philosophy); *A Defence of Prejudice and Other Essays* (1911)
The Higher Patriotism (1915).

IGGINSON, HENRY LEE (1834–1919), American banker,
born in New York City Nov. 18 1834. At the age of 17 he
ered Harvard University, but before finishing his course
ered the banking house of S. and E. Austin, of Boston. He
r went to Vienna for a year, where he studied music. In the
il War he served as a volunteer officer. In 1863 he was severe-
wounded at Aldie, Va., and in the following year was honour-
y discharged. In 1868 he joined the banking firm of Lee,
ginson and Co., of Boston, with whom he remained until
death. His interest in music led to his founding the Boston
nphony Orchestra in 1881. A long line of distinguished direc-
s placed this organisation in the first rank. It was a stimulating source of musical education in America and won full recognition abroad. In 1891, as a memorial to certain friends who died in the Civil War, he presented Soldiers' Field to Harvard University; and in it the stadium was built. In 1899 he erected the Harvard Union as a general meeting-place for all undergraduates. For many years a fellow of Harvard University, he died in Boston, Mass., Nov. 14 1919. See Bliss Perry, *The Life and Letters of Henry Lee Higginson* (1921).

HIGGINSON, THOMAS WENTWORTH (1823–1911), American author (*see* 13.455), died in Cambridge, Mass., May 9 1911. See *T. W. Higginson: The Story of His Life* (1914), by his wife, Mary Potter Higginson.

HILDEBRANDSSEN, HUGO HILDEBRAND (1838–1925), Swedish meteorologist, was professor of meteorology and director of the Meterological Institute at Upsala from 1878 to 1906. He was an associate member of the Comité Permanent International Météorologique from 1882 to 1885, ordinary member from 1891 and general secretary from 1900 to 1907. In 1886 he undertook, in conjunction with the Hon. Ralph Abercromby, the classification of cloud forms, and he published in 1896 his *Atlas international des nuages* (with Riggenbach and L. Teisserenc de Bort), together with *Les bases de la météorologie dynamique* (1898–1907), in collaboration with Teisserenc de Bort. Hildebrandssen became an honorary member of the Royal Meteorological Society of London in 1888, which awarded him the Symons Gold Medal in 1921, and also a member of the Royal Institution of Great Britain. He died in 1925.

HILL, DAVID JAYNE (1850–), American diplomat, was born at Plainfield, N.J., June 10 1850. After graduating in 1874 from the University of Lewisburg, Pa. (later known as Bucknell University), he became instructor in Greek and Latin there and from 1877 professor of rhetoric. In 1879 he was elected president of Bucknell, and in 1888 of the University of Rochester. In 1896 he resigned and went abroad to study public law. In 1898 he was appointed assistant secretary of state by President McKinley. While in Washington he was also professor of European diplomacy in the school of comparative jurisprudence and diplomacy. In 1903 he was appointed minister to Switzerland, being in 1905 transferred to Holland. He was a delegate to the Second Peace Conference at the Hague in 1907. From 1908 to 1911 he was ambassador to Germany. In 1914 he was proposed as a candidate for the Republican nomination for the U.S. Senate from New York to succeed Elihu Root.

Hill's best known work is his *History of Diplomacy in the International Development of Europe*, embracing *A Struggle for Universal Empire* (1905); *The Establishment of Territorial Sovereignty* (1906) and *The Diplomacy of the Age of Absolutism* (1914). His other writings include *World Organisation as Affected by the Nature of the Modern State* (1911, lectures delivered at Columbia University); *Impressions of the Kaiser* (1918); *Present Problems in Foreign Policy* (1919); and *American World Policies* (1920).

HILL, JAMES JEROME (1838–1916), American capitalist (*see* 13.464), died at St. Paul, Minn., May 29 1916. He resigned the chairmanship of the board of directors of the Great Northern Railway in 1912. He had long thought that the farmers and millers of the north-west needed a large financial institution near at hand to which they could easily turn for aid. Accordingly in 1913 he secured control of the First and Second National banks of St. Paul and merged them, thereby increasing local facilities for loans. On learning in 1914 that friends had raised $125,000 for establishing as a tribute to him a chair of transportation at Harvard he added a like amount. During his later years he gave much attention to the Hill Reference Library, in St. Paul, to which he contributed liberally. He was the owner of a remarkable collection of modern French paintings, including fine examples of Puvis de Chavannes, Corot, Delacrois, Millet and others. He was the author of *Highways of Progress* (1910), a work dealing with the subject to which he had dedicated his life.

HILL, OCTAVIA (1838–1912), British philanthropist (*see* 13.465), died in London Aug. 13 1912.

HINDENBURG, PAUL VON (1847–), German soldier. Paul Ludwig Hans von Beneckendorff und von Hindenburg was born in Posen Oct. 2 1847, the son of a Prussian officer. His childhood was spent in his parents' house, and later in Pinne and Glogau. In 1858 he entered the cadet school at Wahlstatt in Silesia, afterwards joining the chief cadet academy in Berlin. At an early age the severity of the training in the Prussian cadet corps lent a note of inflexibility to his character, and developed in him strength of will, resolution and cool-headedness. Intellectually, he developed relatively late, owing to early illnesses and to his too rapid physical growth. Ambition awoke in him slowly; but as success crowned his efforts it grew unceasingly, and won him the reputation of a particularly gifted pupil. At the age of 18 he entered the 3rd Foot Guards at Danzig as a second-lieutenant in 1866, and soon after made his first appearance on the battlefield. At the battle of Königgrätz he stormed with his squadron an Austrian battery under fire. He took part in the war of 1870–1 as adjutant to a battalion, and after gaining distinction at St. Privat, became adjutant to the regiment.

After three years at the staff college in Berlin, he served with the general staff in 1877, and was soon promoted to the rank of captain. The next years were spent as company commander and chief of battalion and in various posts on the general staff. In 1883 he became an instructor at the Staff College in Berlin; and later, on the general staff under Count Schlieffen, he was the spiritual pupil and assistant of that strategist of genius. Several years' labour in the Prussian War Office developed his talent for organisation. After serving from 1893 to 1896 as commander of the 91st infantry regiment (Oldenburg), he was promoted major-general, and for four years served as chief of the general staff of the VIII. Army Corps at Coblenz, subsequently commanding the 28th Div. at Karlsruhe for three years. In 1903 he became general in command of the IV. Army Corps at Magdeburg. In 1911, being 65 years old, he was placed on the retired list.

The Outbreak of War.—The outbreak of the World War found him leading a life of seclusion in Hanover. It was in response to the threatening development of the opening campaign in the East against the Russians that on Aug. 22 1914 he was appointed commander-in-chief of the VIII. German Army, and had assigned to him Maj.-Gen. Ludendorff as chief of staff. Though hardly acquainted with one another previously, a reciprocal confidence soon resulted, which, despite divergence of character, led to a unity of thought and deed without analogy in history. Hindenburg has given a detailed account of his relations with Ludendorff in his memoirs. When, in Germany, after the War, from personal and political motives, attempts were made to make a scapegoat of Ludendorff, the marshal denied these accusations, saying: "We belong to one another till death. Gen. Ludendorff acted in constant accord with me. He who strikes at him strikes at me." General Ludendorff, too, in his war memoirs, fully reciprocates this attitude of complete trust and confidence.

It must be recognised that the disposition of Ludendorff was the more active, that a demonic spirit resided in him which was responsible for those decisive acts which changed the course of the world's history. His memoirs of the War and his demeanour in German politics after the War are instinct with the vehement passions of one who has been subjected to many attacks, just or unjust. During the War it was only the presence of the marshal's authority that prevented the vivid, sensitive and at times well-nigh fanatical temperament of his colleague from losing self-control. The character of Ludendorff was the harder, that of Hindenburg the greater. Their processes of thought ran upon separate lines, but each tested his own conclusions and completed them by reference to the other. Ludendorff bore the whole burden of the technical execution of the decisions, a task which he carried through with titanic strength. Hindenburg remained predominantly in the sphere of pure thought, supplying rather the static element in leadership, and leaving the dynamic side in the other's hands.

Hindenburg possessed a gift of inestimable value, and Ludendorff enabled him to develop it—that of economising his own mental energy and guarding it against strain and premature exhaustion. He was thus enabled to retain his nerve force unti end of the War, when he was then able to assume a heavier more thankless task, that of saving his fellow-countrymen the whirlpool of the revolution. In the political sphere, Ludendorff's vigorous intervention frequently involved the shal in spite of all his distaste for political activities, in q tions which he would probably have otherwise avoided. Hin burg as a soldier was hampered by mistrust of his own poli ability. Ludendorff frequently had to convince the chief of general staff of the necessity for taking political decisions. the constraint of conscience and the sense of moral responsib caused Hindenburg and Ludendorff to intervene at all in polit questions.

Tannenberg.—The battle of Tannenberg, which lasted Aug. 26 to 31 1914, found its origin in the dispositions, invol the assembly of strong forces on the southwest flank, adopte the superseded Gen. von Prittwitz after breaking off the gagement at Stallupönen (Gumbinnen). Hindenburg's m lay in converting the possibility thus acquired of a successful fence against Samsonov's Russian Army of the Narew in victory, whereby despite the numerical inferiority of the mans the enemy were twice encircled and practically annihila The most brilliant feature of the operations was the concen tion of all available forces in order to overwhelm this ene despite the threats to Hindenburg's rear, first by Rennenka in the north and later by new Russian forces which were proaching from the south. In the subsequent battle of the surian Lakes, Sept. 7–12, the Niemen army under Rennenka was so thoroughly dispersed in the wood and marsh lands as t unfit for further operations for weeks. In the opening of his c paign in East Prussia Hindenburg showed consummate mas in the employment of interior lines and in using a central posi to prevent hostile forces which were advancing from diffe directions from uniting on the battlefield. His plan was to o whelm the first of these with lightning swiftness, and then to t with all his strength upon the others.

Hindenburg was unable to follow up his victories in E Prussia by advancing across the Lower Narew; the Aus Hungarian allies had suffered a heavy defeat in Galicia, and German commander was compelled to hasten to their immed aid with the bulk of the German forces available in the E This led to the combined offensive of the German IX. A through Southern Poland towards the Vistula and of the Au ans in Galicia across the San. The German advance met little resistance, but the roads were mere morasses. On Oct the Vistula was reached between Jozefoff and Dęblin (Iwange after an advance along the Opatow-Radom line. The attempt cross the river failed, and the Austrian allies, too, came t standstill. Finally, the German offensive drew upon itself gre superior Russian forces which, advancing past Warsaw, assa its left flank. In this way the ally was relieved. Hindenb himself succeeded in escaping the threatened envelopment fr the north by a timely withdrawal upon Upper Silesia. With vision of genius he grouped the great bulk of his forces about railway line running to West Prussia, and at the beginning Nov. advanced in a surprise attack from the Wrzesnía-Th line upon the right flank of the main Russian forces lying southern Poland. He succeeded at the battle of Lódź in bringi the "Russian steamroller" to a standstill, and eventually c pelled the enemy to withdraw behind the Bzura and Rawka.

Further Operations in the East.—Hindenburg in the meanti had been appointed marshal and commander-in-chief of all German forces in the East. His next blow was in Masuria Feb. 1915 against the northern wing of the Russian Army the Upper Bobr, and led to the annihilation of the X. Russi Army. But the attempt to advance across the Narew to Bia stok failed, owing to a powerful Russian counter-offensive Prazasnysz. The general eastern campaign, directed by G von Falkenhayn, was now concentrated upon Galicia, where May 8 the break-through at Gorlice-Tarnow initiated a prom ing offensive. The front line of the army group of Hindenbu stretching from the upper Vistula as far as Courland, remai onary throughout this period, except for local offensives and ge scale cavalry raid. Not until the middle of July was lenburg's front-line set in motion, in co-operation with the rious progress of the offensive in Galicia and southern nd. But Gen. von Falkenhayn and the Marshal differed amentally in their attitude towards the cardinal problem of War. Hindenburg's conviction, founded on the teaching of sewitz, was that the salvation of the Central Powers depend- the destruction of the Russian colossus. He believed that a t " Cannae " was attainable in the East, and that with such tory all political and military considerations which fettered ommander in his power of decision would vanish.

lkenhayn, on the other hand, held that it was sufficient by ns of a " campaign with limited objectives " to keep the sian Army at bay and to cripple its offensive power. Hinden- 's proposal was to take the offensive on his extreme left on the Niemen northwards past Kovno in the direction of a and beyond, and thus to sever the northern arteries of Russian Army—namely, the railways. This plan was rejected alkenhayn in favour of the advance across the lower Narew, h proved successful, for in conjunction with the successes of kensen and of the Austrians in southern Poland it caused the le Russian front line to waver. Yet it was only gradually and nsequence of continual front-line engagements that the enemy wed themselves to be driven back upon their rearguard munications towards the East. Several times during the ations Hindenburg brought up the question of his original ect; he also carried out unaided the attack upon the fortress ovno, which fell on Aug. 18. Eventually, early in Sept., enhayn gave way ostensibly, without, however, placing at denburg's disposal the strength requisite for carrying out his s. The offensive upon Wilna, begun too late, encountered erful Russian forces, and it was only possible to press back Russian front line, no decisive encounter having taken place.

rom the autumn of 1915 onwards Gen. von Falkenhayn ted the East as a merely subsidiary seat of war; for while he striving to wear down the French forces at Verdun the Ger- eastern front was condemned to inactivity. This facilitated great Russian successes in June and July against the Austro- garian front, which was broken through and almost shat- d at Luck. In Aug. when the danger was at its greatest, the le of the eastern front from the Gulf of Riga to Galicia was ed under Hindenburg. He brought order where chaos had ned. On the upper Sereth, at Brody and on the Styr a new part arose, which, however, proved tenable only where Ger- troops stiffened their allies' resistance. Meanwhile the ggle for Verdun continued to rage, and the battle on the me reached its culminating point.

t Headquarters.—When in Aug. Rumania joined the Entente, Marshal, who was now the national hero, was appointed f of the general staff in place of Falkenhayn, while Gen. endorff remained with him as quartermaster-general. The German High Command found itself confronted with in- merable heavy tasks. While the campaign against Rumania to be improvised, it was necessary to stand on the defensive he West. The offensive against Verdun was abandoned, not hout the French having gained numerous local successes to- rds the end of the year. Hindenburg expressed his final aim he words: " We intend, not to hold out to the end, but to quer." An intensive submarine campaign was carried out as ply to England's hunger blockade.

n the East every nerve had to be strained to force Russia to ke a separate peace, while in the West the defensive cam- gn continued. The end of 1917 found the Quadruple Alliance, pite the tremendous demands made upon their strength— , despite the fact that they were almost exhausted—consider- y nearer to their objective. The U-boat warfare was slowly surely producing its effect. The Italians had in a brief but verful offensive been, not indeed annihilated, but decisively eated. In the East the German hammerblows at Tarnopol, Riga Osel (Saaremma) had broken the fighting spirit of the new ssian ruler Kerensky, and carried the Bolsheviks into power. Peace was negotiated with them and with Rumania at Brest-Litovsk and Bucharest and, under military pressure, was finally attained in the winter of 1918. There remained the last and hardest task, the reckoning with France and England in the West, before America should be in a position to intervene as a military factor in the War on land.

In the spring of 1918 Hindenburg set himself to place the cornerstone upon the structure of his military achievements. All available effectives were utilised for this decisive conflict. The great offensive on both sides of St. Quentin was to break through the front line of the French and British on the southern flank of the latter, to roll them up towards the north and drive them towards the coast. From the tactical point of view the first blow in the direction of Amiens was a brilliant success. But it led to no practical advantage, and was supplemented by the attack upon the Lys front. But, here, too, the operations for a break-through miscarried, resulting only in a second massive concentration on the enemy front. Hindenburg, notwithstanding, clung to his resolve to deal the British a decisive blow in Flanders.

It was necessary, however, to effect a diversion in order to draw off the French reserves and to occupy them elsewhere. This led to loss of time, from which the enemy derived advantage. For the intervention of America loomed threateningly near. The first diversion at the Chemin des Dames gained considerable ground and drew in a large number of the French reserves, but not enough to pave the way for the decisive blow in Flanders. A new diverting attack on both sides of Rheims failed, whereupon Marshal Foch seized the initiative and from Villers Cotterêts attacked the German Marne position on the flank with strong forces. The Americans now appeared in the capacity of attacking troops. Hindenburg abandoned the Marne salient and held up the break-through on the Vesle. But from henceforth the initiative remained steadily in the hands of the French generalissimo, while the German reserves melted steadily away.

From a military standpoint the War was lost with the reverse of Aug. 8. Yet Hindenburg still hoped to cripple the fighting spirit of the enemy by a strategic defensive and to secure a peace compatible with the dignity of the German people. But Bulgaria's defection caused the complete collapse of the Macedonian front, and Hindenburg realised that an immediate armistice was necessary to give the army breathing space. With a just appreciation of their prospects of victory, the enemy took their time over granting an armistice, and summoning the full strength of their tremendous material superiority proceeded to force the German Army to throw in its last reserves. Meanwhile Turkey and Austria abandoned their rôles as allies of Germany, who found herself flung entirely upon her own resources in the final struggle. Hindenburg and Ludendorff wished to rouse the people to a final heroic effort of exertion; but the Cabinet of Prince Max of Baden lacked the capacity to check the revolution, and Germany was handed over unconditionally to the dictates of the enemy.

The marshal, victor in countless battles, had to return home, therefore, not as supreme war-lord but as a beaten general. Yet even in misfortune and profound humiliation his spirit remained unbroken, and he succeeded in extricating his country from the disorder of the revolution. On April 26 1925, the German people elected him President of the Reich.

Hindenburg stands out as the typical German, a personality of classic mould, unbroken by the tragedy of his life. He had a profound understanding of all human affairs, and he was thus enabled to pursue a steady line of conduct and to adhere to it during the appalling downfall of his country.

(W. F.)

HINDUISM (*see* 13.501).—In Hinduism we may discern four main elements: religion, race, country and social organisation. They may not be separated. They are inextricably interwoven.

The life of each is bound up and is an integral factor in the life of the others. It is a living whole forged by the organic stresses of history and a long past, from diverse sources from various materials and it is still a living vigorous whole.

Its diversity is appalling. Uniformity could not be expected as a feature of the religious experience of 232,000,000 people of different racial origins, of different history, of different environment, tradition and social structure. Yet there is a true Hindu polity: there are features common to North and South, to East and West. Much of it belongs obviously to the universal pattern for the agelong problems, whose presentations, at various times, in differing modes, constitute the stimulus to religious activity, are based ultimately on certain definite universal experiences and facts. Man is born of woman, grows and withers like the grass. Whence and whither and why? The debate of fate, foreknowledge, freewill follows inevitably certain lines, and the solutions to these problems conform to type because they are universal problems, wherever, as is markedly the case in India, thought has turned to the scrutiny and analysis of experience.

What of unity is there in all this? Where is it to be found? What is the factor or force that transcends this welter of diversity and binds it into a whole? Not community of origin, not community of speech. A clue may be found in the view that " Though Hinduism has no one creed, yet there are at least two doctrines held by nearly all who call themselves Hindus. One may be described as polytheistic pantheism . . . the second doctrine is commonly known as metempsychosis, the transmigration of souls or reincarnation, the last-named being the most correct." Here most certainly are elements which Hinduism shares with and derives from lowlier cults. From these very elements and beliefs, the social fabric draws its strength. The new-born child is no stranger, dropped from the skies: he is one of the community returning for a brief while to the world to which again and again he will come till liberation shall have been won. These beliefs we now know to be part and parcel of the socio-religious manifestations of many so-called savage tribes. They make for the stability of social structure. They validate morality. They have a survival value.

The Hindu does not admit that a belief in reincarnation expresses pessimism. By judicious and timely expenditure a sinner may escape hell, but he cannot escape a disadvantageous rebirth—a belief which establishes a closer and more vital and socially valuable connection between morality and religion, which he cannot discover in other types of religion. What gives perennial force to these beliefs is their practical relation with the structure and rules of Hindu society and their ethical value.

In another aspect this belief lays emphasis upon the continuity of life while recognising to the full that change is ceaseless. The continuity of the Universe, which to a materialistic world is enshrined in the scientific dogmas of the indestructibility of matter and the conservation of energy, is a real doctrine of perpetual validity and practical ethical import in Hinduism, which recognises a material law in the spiritual world, as well as a spiritual law in the material world.

The charge is brought that Hinduism exhibits both intellectual and moral extravagance, yet the value of truth and of progressive revelation in religion is rated high. The moral extravagance, as the West judges morals, which exists in Hinduism, is in large part the result of the intellectual extravagance whereby logic is exalted to perilous heights unchecked by reason.

Is it absurd to affirm that Deity cannot be fettered, must be free in all respects, may act when and where and as it will? If this be true of the Divine, then in like measure as some men are the vessels of divinity, so will they be set free from the trammels and conventions that bind the ordinary lesser man. Such at least would seem to be the argument. The consequences drawn from it justify the criticism that what may be true of the Divinity is in practical reason inapplicable to humanity.

The sense of mystery, the recognition of power, the apprehension of an order dimly seen but always felt, are there. Hinduism provides a mode of life as well as a religion, a guide to an interpretation of the relations between man and man, bet one group and another, between humanity and divinity. regulate these relations, to secure safety for all, there are mi observances and ordinances which seem to be, but at de view are not, incongruous with the philosophic subtlety charac istic of Hinduism at its highest and best.

Hindu polity is aristocratic, not egalitarian. It recog and utilises and explains the inequalities of individuals an groups of individuals. It is based on a sense of duty an reciprocal obligation permeating the whole society from King to the peasant. *Dharma* is duty. In the caste sys with its hierarchical gradations, its complex relations, its jea endogamy, its fissiparous nature, it expresses an exclusive which at first sight seems to create a rigid barrier, but its pro of proselytisation is by the absorption of whole communi and that process is still active. The groups find a place, and s in course of time are known to have risen high by use of polit and other circumstances. The highest height is still reser for the Brahmin who, when a long view is taken of Indian tory, has often proved himself worthy of the trust he inherited.

Times are changing. The printing press is active. schoolmaster is in the land. There is talk, loose talk, m talk of rights. Democracy and the ballot box constitute court of final appeal. Ideas spread fast, faster than e knowledge, and wisdom lingers. Yet appeals to the old id are heard and heeded by millions. Saintliness and chara are recognised for what they are, great social forces. An e tional need awakened and created by the stirring political eve of this period was satisfied by the worship of *Bande Mata* the symbolic identification of a religious entity with a ra and political ideal.

The old spirit lives and exerts its influence in countless wa The development of industrialism in India has already m vast alterations in the mode of life of millions by changing distribution of wealth and by augmenting the range of hum and social ambitions. Those who but yesterday were poor without honour, today are prosperous and seek for esteem recognition. Hindu polity in the social order is based on principle of " attaching more importance to the differen between social groups than to that which they have in co mon." Wealth is power and power is worshipful always. W dom, too, is power and still has its meed of respect, thou perhaps not as fully as in the golden days, when great was " influence exercised by Indian philosophers in every grade society, from the highest to the lowest, solely by reason of th superior intellectual qualities and personal virtues."

Much has been, much yet remains to be, learnt by the seri student of religious and social problems from the vast array Indian religious experience in which, daily, fresh contacts established between Hinduism, Islam, Christianity and Pri itive Culture. The diversity, polytheism, philosophic mo theism, practical henotheism, of Hinduism affect profoun and intimately all it touches, and it assumes fresh forms a provokes change and reaction within the religious communit it touches. The census records display losses and gains a analyse them fairly. Within it the cement of philosophy wh binds together the aboriginal beliefs, its prime material, is strong as are the reforming movements like the Brahmo Sa which, judged by numerical standards, is weak, even declin but is ever gaining fresh hold on the intelligentsia, especiall Bengal. The Arya Samaj in the Punjab has gained greatl recent years. It has developed the practice of *Shuddhi:* (*a*) t conversion to Hinduism of persons belonging to foreign religi (*b*) the reconversion of those who have recently or at a rem period adopted one of the foreign religions; and (*c*) reclamati of the so-called Depressed Classes. In conservative Southe India whence great movements have originated in the past, much so that " it would be more correct to describe Indi religion as Dravidian religion stimulated and modified by t ideas of Aryan invaders," many forces are at work which a ined surely to find expression in religious modes, perhaps efore, in a development of an emotional theism founded on belief that "every man by his own efforts can come into ediate contact with the Great Being whom he worships." induism needs no apology. As Sir Charles Eliot has finely : "If Hinduism were really bad, so many great thoughts, nany good men would not have grown up in its atmosphere. re than any other religion it is a quest of truth and not a d . . . it is truly dynamic and in the past, whenever it has ned in danger of withering, it has never failed to bud with life and put forth new flowers. More than any other religion duism appeals to the soul's immediate knowledge and ex- ence of God. It has sacred books innumerable, but they e in little but this, that the soul can come into contact and macy with its God, whatever name be given Him and even Ie be superpersonal . . . the task of religion is . . . not to mote the welfare of tribes and states, but to effect the en- tenment and salvation of souls." Purified from within, duism in its highest expression by which it, as any other gion, has a right to be judged, with its great vitality, its power adaptation, its philosophic tradition, its insistence on the elopment of the powers that are latent in man and are in pardy of being atrophied by modern dependence on machin- , may yet serve humanity by correcting the stress laid by er schools of thought upon the material to the neglect of spiritual.

IBLIOGRAPHY.—The Census reports for 1911 and 1921 contain uable data and critical examination of the statistical evidence ected. The Provincial reports are also full of matter. The lication of *The Tribes and Castes of Bombay*, 3 vol. (1920), com- es a series of most important books so far as the main part of tinental India is concerned. The religions of the Lower Culture dealt with in the *Birhors*, by Sarat Chandra Roy (1925) and the nographs of the Assam and Burma Ethnographical Surveys. ir Charles Eliot's *Hinduism and Buddhism* (1921) is a fine pre- tment of facts based on personal knowledge and a critical investi- ion of the texts. Such works as *The Crown of Hinduism* by J. N. quhar (1913), *The Chamars* by G. W. Briggs (1920) and *The lage Gods of Southern India* (1921) by the Rt. Rev. Henry White- d, D.D., may also be consulted.

IINES, WALKER DOWNER (1870–), American lawyer, s born at Russelville, Ky., Feb. 2 1870. He was educated at den College and the University of Virginia. From 1893 to 4 he was with the Louisville and Nashville Railway in the al department and, after 1901, as first vice-president. He ctised law in Louisville, Ky., 1904–6 and in New York City 6-16, becoming specially versed in questions of interstate nmerce. In 1906 he became general counsel for the Atchison, peka and Santa Fé Railway, later becoming also chairman of executive committee, and then chairman of the board of ectors. In Feb. 1918, after the U.S. Govt. had assumed con- l of the railways as a war measure, he was appointed assistant ector-general, and in Jan. of the following year director- neral. He resigned in May 1920, and was designated by Presi- t Wilson as arbitrator in the distribution of German, Aus- an and Hungarian inland shipping under the Peace Treaties. Oct. 1921 he resumed the practice of the law in New York ty. In 1925 he made an investigation and report of navigation the Rhine and Danube for the League of Nations.

HIPPIUS, ZINAIDA (1869–), Russian poet and prose iter, was born Nov. 8 1869 at Belev, in the Tula province. She rried Dmitry Mereshkovsky in 1889 and went to live in Petersburg (Leningrad). Later she went to live in Paris. Hip- us was one of the leading poets of the Russian symbolist move- nt of the 'nineties and her poetry bears the usual character the movement: the cult of beauty, mysticism and individual- n. The influence of Nietzsche's philosophy is also apparent as in famous line "I love myself as I love God" which became the gan of the Russian "decadents." Her later poetry shows the luence of the neo-Christian theories of Mereshkovsky but at same time reveals deep individual and emotional power. Her ose works were much inferior to her poetry, but under the pseu- nym of "Anton Krainy" she was known as a trenchant liter- critic.

HITCHCOCK, GEORGE (1850–1913), American painter (*see* 13.533), died on the island of Marken, Netherlands, Aug. 2 1913.

HITCHCOCK, GILBERT MONELL (1859–), American politician, was born at Omaha, Neb., Sept. 18 1859. He was educated at Omaha and Baden-Baden (Germany), and the law school of the University of Michigan. He was admitted to the bar in 1881 and practised law in Omaha for four years. In 1885 he founded the Omaha *Evening World*, and four years later bought the Omaha *Morning Herald*, combining the two papers into *The World-Herald*. He was representative in Congress 1903–5 and 1907–11. He was elected U.S. Senator for the terms 1911–7 and 1917–23. After the sinking of the "Lusitania" in 1915, he believed that action on the part of America should be limited to a demand for reparation. In 1917, however, he supported the resolution for a declaration of war against Germany, and in 1918 became chairman of the Senate committee on foreign relations. When the President submitted to the Senate the Treaty of Versailles, Senator Hitchcock led the administration forces by virtue of his office, giving strong support to the League of Nations.

HOBART, Tasmania (*see* 13.544), the capital of Tasmania, is the political and social, but not the commercial or trade centre, as it is reached from the north coast by a slow railway journey. Since electric power has been available from generating works at Great Lake, which began to give a large output in 1921, zinc works, a chocolate and sweet factory, and carbide manufacturing works, have been started near the town. A large number of summer visitors from the Australian mainland provide a livelihood for many inhabitants of Hobart, which had a population of 53,132 in 1921 (including suburbs), representing a quarter of the population of Tasmania. The magnificent sheltered harbour in the river Derwent, which is 2½ m. wide at Hobart, has some 2½ m. of wharfage, with depths of 45 to 65 ft. alongside the pier.

HOBHOUSE, LEONARD TRELAWNEY (1864–), British sociologist, was educated at Oxford; he became fellow of Merton College in 1887, and of Corpus Christi in 1890. Engaging at first in journalism, he served for five years on the staff of *The Manchester Guardian*. An active Liberal, he was secretary of the Free Trade Union in 1903–5 and published several political works, notably *The Labour Movement* (1893; 2nd ed., 1898) and *Democracy and Reaction* (1904), showing strong sympathy with collectivism, which he maintained to be not inconsistent with Liberalism. But in 1907 he was appointed Martin White professor of sociology in the University of London, and next year became editor of *The Sociological Review*. Thenceforth, except for a few war publications, he devoted his energies to writing and lecturing on ethical, psychological and sociological subjects. His principal works are *The Theory of Knowledge*, 3rd ed. (1921); *Mind in Evolution*, 2nd ed. (1915); *Morals in Evolution*, 2 vol., 3rd ed. (1915); *Development and Purpose* (1913); and *Principles of Sociology* in four separate sections (1918–24); the social application of ethical principles; in collaboration with G. C. Wheeler and M. Ginsberg, *The Material Culture and Social Institutions of the Simpler Peoples* (1915); and with J. L. Hammond, *Lord Hobhouse; a Memoir* (1905).

HOCKEY (*see* 13.554).—Since the World War, hockey has definitely established itself in Great Britain as a very popular game. During the years immediately before 1914 there was a steady increase in the number of clubs affiliating to the various county associations, and also in the number of teams put into the field. To-day there are about 1,000 clubs in England alone. In Ireland, the game more than held its own, but in Scotland and Wales there was little or no progress, due in some measure to lack of suitable grounds. In the services and at the universities, however, every year saw new adherents to the game, and since 1908 Cambridge has given a "full blue" for hockey. In 1910 the foreign countries in which hockey was played were France, Germany, Belgium, Denmark and the Netherlands. An annual match was instituted between England and France in 1907 and in 1913 Germany was also met. Turning to British dependencies, we find associations flourishing in Australia, New Zealand, South Africa and India.

The post-War period in Great Britain is noteworthy for the fact that the game is rapidly becoming more democratic. This is largely due to the initiative of the large banks, insurance companies and business houses in providing larger and better grounds for their employees. A newcomer to the ranks in the services is the Royal Air Force, which has some 30 affiliated stations. This arm of the services, together with the navy and the army, form the Combined Services Hockey Assn., which plays annual matches with one or other of the five divisions into which the English counties are grouped. The number of public schools playing hockey is now considerable.

The Game throughout the World.—It is, however, in foreign countries and, in a less degree, in the Dominions, that hockey has made a large stride forward since the World War. Taking Europe first of all, Spain, Austria, Switzerland and Czechoslovakia, have many flourishing clubs. The French have taken to the game with enthusiasm, and they hold inter-regional matches, corresponding to the divisional matches held in England. The Belgians are forging ahead and the Germans have a large number of players, Hamburg being the chief centre.

Turning to the Dominions, Australia and New Zealand are making headway. In South Africa, too, the game is increasing in popularity, with the result that in 1925 a South African Federation was formed. But so far as numbers are concerned, India is the biggest hockey country in the world. It is roughly computed that there are about 3,000 teams in India and recently an All-India Federation was formed to include the 24 provinces. The game in India is generally played all the year round; the natives are very fast and amongst them are many clever players. Japan is a newcomer to hockey and has formed an association to which some 50 clubs are affiliated. The Japanese Army and Navy have also included the game in their athletic curriculum and there are several service teams. In China a few of the more educated Chinese prefer hockey to association football, and it is extensively played in China by foreigners of various nationalities, principally in Hongkong, Shanghai, Pekin and Tientsin.

Frost and H. J. Cubberley, *Field Hockey and Soccer for Women* (1923); K. E. Lidderdale, *Hockey for Girls and Women* (1924); see also *The Hockey Annual*, and *The Hockey and Amateur Football Monthly* (London). (S. H. S.)

United States and Canada.—The game of Ice Hockey is native to Canada and was first played in an organised way in the cities of Kingston, Quebec and Montreal and before many years it was the acknowledged national winter game of the country. The game was introduced into the United States in the early 90's, when Canadian teams played in New York City and Baltimore. To-day it is a recognised winter sport throughout many of the northern states.

Although in Canada and the United States the game is very generally played on open-air rinks, all organised club or league hockey is played in covered rinks. Practically all the covered hockey rinks in the United States and a considerable number of those in Canada have artificially frozen ice surfaces, which give assurance of a good sheet of ice, no matter how the weather conditions may vary during the ice hockey season. In Canada and the United States, organised hockey is played under the jurisdiction of leagues or associations—the professionals, the amateurs, the colleges and the schools having their respective leagues or associations. The playing rules and the laws of the game are fundamentally the same in all leagues or associations. There is some variation in the rules pertaining to off-side play, penalty for fouls, and other minor points.

The principles of the game are quite simple. An ice hockey team is composed of six players, each one having a designated position. There are the goal guard, the right and left defence, and the three forwards—right-wing, left-wing and centre. A stated number of substitute or relief players are allowed each team—not more than six. The game requires steadiness and speed on the skates, dexterity and agility, the capacity to think and act quickly, and physical fitness. The hockey stick is made of elm wood, except for some of the lower grades t may be made from ash. It is with the stick alone that the pla manipulates the object called the puck, which is a disc mad rubber, one inch thick and three inches in diameter. The jective point in the game is to score by driving, pushing or slid the puck through the opponents' goal. Present-day rinks are l out to give an ice surface of anywhere from 180 to 210 ft. lo by 80 to 85 ft. wide. A goal post with nets attached is fixed each end of the ice surface about 10 to 15 ft. from the end boa The goals are four feet high and six feet wide. (T. Ho.)

HODGES, FRANK (1887–), British politician, was b at Woolaston, Gloucestershire. At the age of 14 he entered Vivian Colliery at Abertillery, S. Wales. His fellow miners p vided him with a scholarship to Ruskin College, Oxford, in 19 and he later went to France. Returning to the mines, he a conducted classes in economics and French. In 1912 he beca a miners' agent and six years later secretary of the Min Federation of Great Britain. In 1921 he was made joint sec tary of the National Wages Board. Elected to Parliament 1923 as member for Lichfield, he resigned his post as Secreta of the Miners' Federation. He became a Civil Lord of the A miralty in the Labour Ministry of 1924. He lost his seat at election of that year; and in 1925 was made General Secretary the International Miners' Federation. He is the author *My Adventures as a Labour Leader* (1925).

HODGKIN, THOMAS (1831-1913), British historian (s 13.557), died at Falmouth March 2 1913.

HODLER, FERDINAND (1853–1918), Swiss painter, was bo at Gurzelen in the canton of Berne March 14 1853. He receiv his early education in drawing from a Swiss landscape paint at Thun, but his artistic career began at Geneva in 1872, wh he worked under Barthelémy Menn, at the same time studyi at the university. In 1874 he won the Calame prize for a la scape. After various journeys, notably in Spain, which expla the Spanish influence in much of his earlier work, he settled do in Geneva where, with a few intervals, he remained until h death. Among his most important pictures are the "Cortè des Lutteurs" (1887), "La Nuit" (1891), "L'Elu" (189 "Eurythmie" (1895), "L'Émotion," "La Vérité" (190 "Le Jour," "L'Amour" (1908). He also painted humoro portraits and landscapes, together with many water colou and lithographs. He received many commissions for decoratio from official bodies, notably the large-scale decoration on t wall of the Hall of Arms in the National Museum of Züri called "La retraite de Marignan" (1900). In 1907 he w entrusted with the decoration of the University of Jena, and i 1911 he painted his "Unanimité" for the town hall at Hanove He died at Geneva May 19 1918.

HÖFFDING, HARALD (1843–), Danish philosopher (s 13.561), resigned his professorship at the University of Cope hagen in 1915. Among his later works are: *Moderne Filoso* (1904, English version 1915); *Spinoza's Ethica* (1906, etc.); *Henri Bergson's Filosofi* (1914, English version 1915); *Den st Humor* (1916, English version 1924); *Totalitet som Katego* (1917); *Oplevelse og Tydning* (1918); *Ledende Tanker i det 19 Aarhundrede* (1920); *Relation som Kategori* (1921).

HOFFMAN, MALVINA (1887–), American sculptor, wa born in New York City June 13 1887. She studied sculpture i New York with Herbert Adams and Gutzon Borglum, and i Paris with Auguste Rodin. After obtaining recognition in Paris where she was awarded a first prize at the Salon in 1911 fo "Russian Dancers," she settled in New York. Her memoria group, "The Sacrifice," presented to Harvard University b Mrs. Robert Bacon, but placed temporarily in the Cathedral c St. John the Divine, New York City, is considered the finest c her works. Three portraits by her of Paderewski, when exhibite in New York in 1920, attracted great admiration. Other work of hers are "John Muir" in the American Museum of Natur History, New York City; "Modern Crusader" in the Metro politan Museum of Art, New York City; "Bacchanale Russe in the Luxembourg Musé, Paris, and "Gervase Elwes" i Queen's Hall, London. One of her latest commissions was ic size stone group over the entrance of Bush House, Strand, don. Miss Hoffman was married to Mr. S. B. Grimson e 6 1924 in New York City.

OFMANNSTHAL, HUGO VON (1874–), Austrian poet, born in Vienna Feb. 1 1874. He took the degree of Ph.D. he University of Vienna and when still a schoolboy originated Romantic School in Austria by his lyric and semi-dramatic ry, which aroused much controversy at the time. He was uninfluenced by Stefan George's example and Hermann ir's criticism, but the melody and colour of his language, and art with which he gave poetic expression to complicated itual moods, in particular, were entirely new. A genius for reciating bygone cultures and a sensitive understanding of beautiful in art and in nature, characterised both the youth the man. Hofmannsthal is little indebted to contemporary ism, but his almost too susceptible personality is tinged by umerable literary influences from the Attic tragedians down Victor Hugo, Swinburne, Browning and D'Annunzio. This of originality is especially noticeable in his dramatic poems, a few of which are simply old plays of Sophocles, for example, Calderon, Molière and Otway cloaked in modern form and rit. Nevertheless he has an abiding place in the history of rature as founder of the whole German neo-romantic drama. ew of his dramas became known outside Austria through the sic of his friend Richard Strauss, others through Reinhardt's stival at Salzburg. His collected poems appeared in 1911. In er years he turned his attention to society comedy. The most racteristic of his dramas are: *Gestern* (1892); *Der Abenteurer die Sängerin* (1899); *Der Tor und der Tod* (1900); *Der Tod Tizian* (1901); *Oedipus und die Sphinx* (1906); *Cristinas Heim-r* (1922); *Das Salzburger grosse Welttheatre* (1922); and his retti: *Elektra* (1903) and *Der Rosenkavalier* (1911). See mono-ph by Sulger-Gebing (1905).

HOGG, SIR DOUGLAS McGAREL (1872–), British lawyer l politician, was born Feb. 28 1872, the son of Quintin Hogg, nder of the Polytechnic, London. He was originally intended a business career, and on leaving Eton spent eight years with father's firm of West India merchants. After serving in the ith African War (1899–1902), on his return to England he indoned commerce for the law. Called to the bar in 1902 he thwith took a leading position as a junior, and when he be-ne K.C. in 1917, immediately came to the front. His deadly wer of cross-examination, easy mastery of facts and fig-s and persuasive speech made him formidable in every id of case.

In 1922, on entering Parliament as Conservative Member for irylebone, he became Attorney General and a Privy Councillor Mr. Bonar Law's Government, receiving the usual knighthood en to a law officer. In opposition, or in office he showed him-f a powerful debater, his vigorous speech on the Campbell pros-ution (*see* ENGLISH HISTORY) had not a little to do with the de-t of Mr. Mac Donald's Labour Government. When the Con-vatives returned to power in 1924, Sir Douglas Hogg was re-pointed Attorney General, with a seat in the Cabinet.

(R. S-D.)

HOLLAND, HENRY SCOTT (1847–1918), English divine, was rn at Ledbury, Hereford, Jan. 27 1847. He was educated at on and Balliol College, Oxford; in 1872 he was ordained, be-ming the same year a tutor at Christ Church. In 1882 he was nior proctor of the university, and the same year was made a non of Truro and examining chaplain to its bishop. He was pointed a canon of St. Paul's in 1884, and in 1886 precentor. refused the offer of the see of Norwich in 1893, but in 1910 s appointed regius professor of divinity at Oxford. He died Oxford March 17 1918. Scott Holland was closely associated th the Christian Social Union for many years. He was a suc-ssful tutor and a popular professor; but it is as a preacher at he is most vividly remembered. In 1905 his *Personal Studies*, ich first appeared in *The Commonwealth*, were published in ok form. He also wrote a notable essay on *Faith*, several lumes of sermons and a life of the singer, Jenny Lind. See *fe*, by Stephen Paget (1921).

HOLLAND, JOHN PHILIP (1841–1914), American inventor, was born at Liscannor, County Clare, Ireland, in 1841. He was educated at Limerick, and was a school teacher in Ireland prior to migrating to the United States. He was teaching in New Jersey when the Civil War broke out and the conflict between the "Merrimac" and the "Monitor" suggested to him the idea of a submarine. He became a pioneer in this field and one of the most successful designers of submarine craft. The first boat, built in 1875, was a failure and it was not until his ninth attempt in 1898 that he produced a serviceable submarine from the practical standpoint. This boat was commissioned for the U.S. Navy and orders for others were placed with Holland. His great achievement was the furnishing of the submarine with two methods of propulsion, a 50 H.P. gasolene engine to be used when on the surface and electric storage batteries when submerged. The British Admiralty acquired all the patents for Great Britain, although his avowed purpose had been to invent a craft that would overcome the British naval supremacy. Holland then turned his attention to the construction of submarines for sea-going purposes, constantly improving upon his original model, and all his subsequent boats were built for the U.S. Navy, the types tending constantly to become larger. He died at Newark, N.J., Aug. 12 1914.

HOLLAND: *see* DUTCH LITERATURE; NETHERLANDS.

HOLLYWOOD, Cal., U.S.A., the principal seat of the motion-picture industry, was annexed to Los Angeles (*q.v.*) in 1910.

HOLMES, OLIVER WENDELL (1841–), American jurist, was born at Boston March 8 1841, the son of Oliver Wendell Holmes, the poet and essayist (*see* 13.616). He graduated from Harvard in 1861. On the outbreak of the Civil War in that year he enlisted and served three years in the 20th Mass. Volunteers, rising to the rank of lieutenant-colonel. He was wounded three times—at Ball's Bluff, Antietam and Fredericksburg. He concluded his military career as aide-de-camp on the staff of the 6th Div., retiring in July 1864. In that year he commenced the study of law at Harvard, obtaining his LL.B. in 1866, and was admitted to the Suffolk (Mass.) bar March 4 1867. He practised law in Boston, and in 1870 was appointed instructor in constitutional law at Harvard, at the same time becoming editor of *The American Law Review*, which latter position he held for three years. In 1871–2 he was university lecturer in jurisprudence. In 1873 he edited the 12th edition of Kent's *Commentaries*, since recognised as the standard edition. In the same year he became a member of the firm of Shattuck, Holmes & Munroe and engaged in an active practice.

In 1880 Holmes was appointed lecturer on common law at the Lowell Institute. His articles in *The American Law Review* contained the germs of the lectures which he delivered before the institute, and these in turn, in an amplified form, were published in 1881 under the title *The Common Law*. The object of the work was to present a general view of the common law, and this was done with a wealth of illustration, a charm of language and a clarity of reasoning which, apart from the erudition displayed, gave Mr. Holmes an international reputation. In 1882 he was appointed professor of law at the Harvard Law School, but resigned to accept an appointment on Dec. 8 of the same year as associate justice of the Supreme Judicial Court of Massachusetts. This position he occupied for 17 years, becoming Chief Justice on Aug. 2 1899. On Dec. 4 1902 he became an associate justice of the Supreme Court of the United States. As a judge his opinions are conspicuous for their literary style and epigrammatic force. In 1924 he was awarded the Roosevelt Memorial Association Medal for the development of public law. In addition to the works already mentioned he published in 1891 a small volume of *Speeches*, re-issued with additions in 1913 and *Collected Legal Papers* (1920).

HOLROYD, SIR CHARLES (1861–1917), British painter-etcher (*see* 13.618), died at Weybridge, Surrey, Nov. 17 1917. He arranged for the transference of a large portion of the Turner bequest to the Tate Gallery, London.

HOLTZMANN, HEINRICH JULIUS (1832–1910), German theologian (*see* 13.620), died at Baden-Baden Germany Aug. 6 1910.

HONDURAS (*see* 13.649).—A republic of Central America and an original member of the League of Nations. On Nov. 15 1922 Honduras notified the League of its intention to withdraw because of the onerous annual contribution. The area is estimated at 36,000 square miles. The population in 1914 was estimated at 562,000; official figures gave the population in 1923 as 773,408. The capital, Tegucigalpa, had an estimated population in 1923 of 40,000; the population of La Esperanza was 11,453; and that of Santa Rosa 10,574. The inhabitants are mostly Indians and mixed races: there are a few Spaniards and a large proportion of negroes. Honduras broke off diplomatic relations with Germany on May 17 1917, and on July 19 1918 war was formally declared. The constitution of Honduras was remodelled and proclaimed in a new charter on Oct. 3 1924, which gave the legislative power to a congress of 43 deputies in the ratio of one member for every 15,000 inhabitants.

I. POLITICAL HISTORY

In 1910 Miguel R. Dávila (the creature of President Zelaya of Nicaragua), who was elected president of Honduras for four years in 1906, was eliminated in a rapid campaign by Manuel Bonilla, the former president. Dr. Francisco Bertrand, who had been chosen provisional president at a peace conference brought about by the United States, served as vice-president until the death of Bonilla in 1913, when he succeeded to the presidency and was elected to a second term of office in 1915. In the campaign of 1919 a Liberal revolt forced Bertrand to resign office and flee the country. Gen. López Gutierrez, who led the revolt, caused himself to be declared dictator, and was elected president in October.

An attempt to overthrow the President was made by revolutionists from Nicaragua in Aug. 1922; and when, in May 1923, war material of the 1922 movement was discovered near the boundary, new civil disturbances were foreseen. By June many of the citizens had been driven into exile by the warring factions. Further violence marked the presidential campaign in Oct. when Gen. Tiburcio Carias, a Conservative, was opposed to two Liberal candidates. The returns of the election indicated that Carias was the popular choice, although he was a confirmed revolutionist and opposed by the Government. Early in 1924 conflicts between the three presidential candidates, Dr. Arias, Dr. Bonilla and General Carias, caused American casualties, and marines were sent to the Nicaraguan boundary and to Tegucigalpa. In April 1924 Mr. Sumner Welles was sent by President Coolidge to arrange a conference between the contestants and the neighbouring republics at Amapala. The conference was successful, and Gen. Vicente Tosta was elected president with the moral support of the United States, superseding Gen. Fausto Dávila, the provisional president.

At the beginning of July, as no arrangement could be made regarding the future president, serious disaffection was manifested and political disturbances again broke out. Both the political leaders and the revolutionists accepted Dr. José María Caseo and Ramón Alcero Vastro as president and vice-president respectively. The election at which a successor to provisional president Tosta was to be chosen was postponed from Nov. 25 to Dec. 28–30. The elections were held on the postponed date without any disorder, and Dr. Miguel Paz Baraona was elected president, with Presentación Quesada as vice-president. The new president was inaugurated on Feb. 1 1925. In March diplomatic relations with the United States, which had been severed in Feb. 1924 were resumed. In 1925 political disturbances were recurrent: Tegucigalpa was held in a state of siege in May by revolutionists, and in the west Gen. Gregorio Terrera had been actively in rebellion since February. Nicaraguan and Honduran officials prevented revolutionists from Nicaragua entering the country. Martial law prevailed. In Aug. General Tosta, as Minister of War and Marine, announced at Tegucigalpa that peace had once more been restored. Honduras ratified the first three of the Washington conventions of 1922–3, and the 13th, providing for international commissions of inquiry (*see* CENTRAL AMERICAN UNION). In Aug. 1925 eight of the agreements were awaiting the final approval of the republic.

Defence.—Military service is compulsory for all citizens Honduras on attaining the age of 21. Under the conventi signed at Washington on Feb. 7 1923 the standing army of the public was limited to 2,500. A congressional decree of Apri 1923 fixed the strength of the regular army at 3,036 of all ran

Education.—Primary education, which is secular, is free a compulsory from seven to 15 years of age. The number of c dren who do not receive instruction is high, estimated at 57 Of 79,199 children of school age in 1922 it was estimated t 32,976 attended school. In 1922 there were 850 public scho with 1,127 teachers. There were five public secondary scho and four training colleges. The National University at Tegu galpa was staffed in 1922 with 36 professors and attended by students. Military and aviation schools have been established the capital, and a school of jurisprudence at Comayagua. T Government offers two exchange scholarships with the Unit States. Expenditure on education in 1919 was 384,980 pesos.

II. FINANCIAL AND ECONOMIC HISTORY

Finance.—The budget of 1923–4 was adopted by Congress the budget for 1924–5 owing to political disturbances in 19 Revenue and expenditure were estimated to balance at 9,204, silver pesos; the budget for 1925–6 was estimated at 10,832,4 pesos. The fiscal years 1914–5 to 1920–1 showed a deficit; s pluses occurred in the years 1921–2 to 1924–5. Recent politi warfare has, however, eliminated all surpluses. Military expe iture was the largest item in the budget, constituting in the cal year 1920–1 45% of all government expenditure. The forei debt, as reported by the Corporation of Foreign Bondhold amounted in Oct. 1924 to £29,114,775. The contract for the justment of the external debt was approved by the Council Bondholders and forwarded to the National Congress for sa tion. This ratification had not been given by Feb. 1926. T basis of the arrangement took the sum of £452,000 as the rep sentative value of the external debt incurred in the wars of 18 1869 and 1870, and interest on this sum at 8·86% was allowed the period of the new agreement. The total payment was to con of £1,200,000 in semi-annual instalments of £20,000 for 30 yea

Production and Industry.—Business prosperity was depres in 1923 and 1924 by wars. In the early part of 1925 compl stagnation followed bad political conditions, banditry on frontiers and floods in the fruit districts. The principal cult is that of bananas and coconuts. In 1920 the export of bana was 11,524,149 bunches; in 1923 the exports were 12,520,4 Coconuts dropped from 12,647,508 in 1920 to 8,360,720 in 19 The 1924 sugar production in the Puerto Cortes district, 30,5 950 lb., was twice that of 1923 and four times that of 1922. T prospect was that the 1925 production would show a further crease. Silver production increased in 1924, when more th 2,000,000 oz. were produced. Bananas rank first in order of i portance amongst the exports, and next in order are sugar, silv coconuts, hides, cattle, gold. Imports, in order of importan are manufactured products, foodstuffs, raw materials and lumb The United States has 90% of the trade. The chief figures trade totals of three years were:—

	1924	1925
All countries		
Imports	11,137,917	12,752,761
Exports	7,897,046	11,983,051
United Kingdom		
Imports	401,218	295,921
Exports	658,320	203,888
Germany		
Imports	198,792	308,197
Exports	10,485	28,170
United States		
Imports	9,783,811	10,252,257
Exports	7,186,045	11,072,463

Communications.—The national railway of 66 m., which w taken over by the Government in 1912, was in 1920 placed in t rol of the Compañía Agrícola, which in 1924 was reconsti- d as the Cortes Development Company. The line has been hauled to meet the demands for transporting the banana s. Four other railroads are owned by fruit companies. In the mileage of the railways was 934. Telegraph lines in 1922 lled 4,662 and telephone lines 873 miles.

BLIOGRAPHY.—*Bulletins of the Bureau of the American Republics* shington, monthly, 1893, etc.); D. G. Munro, *The Five Repub- of Central America* (Carnegie Endowment for International e, Div. of Economics and History, Washington, 1915, etc.); . Robertson, *History of the Latin-American Nations* 5). See also Department of Overseas Trade, *Reports on the omic and Financial Conditions in Honduras.* (H. I. P.)

ONDURAS, BRITISH (*see* 4.615).—A British Crown colony entral America. Its area is 8,598 sq. m. and the estimated ılation (1923) is 45,527; the birth rate was 37·91 per 1,000 the death rate 20·50. Belize, the chief town, had a population 921 of 12,661. In 1923 there were 65 primary schools with 4 pupils on the registers. The Government expenditure on ic education in 1923 was £10,615. There were five private ols conducted by religious institutions, with 499 pupils.

inance and Commerce.—The chief sources of revenue were oms duties, excise and land tax and the sale and letting of wn lands. Revenue and expenditure for the four years -4 were:—

	1920–1	1921–2	1922–3	1923–4
venue	£232,496	£227,409	£234,059	£224,928
penditure	191,114	290,284	226,114	247,576

toms duties levied on the majority of imports were, in 1923–4, ,969; preferential treatment is accorded to goods of British in, 10% *ad valorem* being accorded to manufactured goods. orestry products are the chief source of the colony's wealth, agriculture has tended to engage the population. The forest was estimated at 4,000,000 ac., or nearly one-half of the re area; and 9,967,186 superficial ft. of mahogany were ex- ed in 1923, as well as 663,437 superficial ft. of cedar wood. ıitive methods of cultivation employed have prevented the lopment of banana cultivation: in 1923, 332,500 bunches of ınas were exported, and 5,964,706 coconuts. The chief orts were, in order of importance, clothing and articles of ırel, foodstuffs, cotton goods, hardware and machinery. balance of trade was adverse during the years 1922–4. total trade figures were:—

	1921–2	1922–3	1923–4
ıports	£688,000	£692,716	£830,594
ports	627,000	593,178	657,794

922, 71% of the export trade was with the United States and 8% with Great Britain.

he United States gold dollar is the monetary unit, and ish and United States gold coin are legal tender. In 1912 king business was taken over by the Royal Bank of Canada. osits in the six Government savings banks were in March 4 $164,236.

e A. B. Dillon, *Geography of British Honduras* (1923); *Colonial e Reports*, annual series, London.

ONGKONG or HIANG-KIANG (*see* 13.657) is an island off southeast coast of China, 11 m. long and from 2 to 5 m. d. It is a British Crown Colony and was ceded to Great ain by the Chinese Govt. in 1841. The total population of gkong and the leased territory of Kowloon was estimated 3) 681,000, of whom the majority are Chinese British sub- s. At the Washington Conference the Chinese delegates asked c. 3. 1921) for the surrender of all the leases of Chinese itory, including Kowloon, to foreign Powers, but Mr. (Lord) our declared that Great Britain could not contemplate the ender of Kowloon, as without it Hongkong would be strate- lly untenable. He also pointed out that Hongkong ranks "easily first among the ports of the world," was a free port and therefore that its preservation was not only a British but a world interest.

Shipping and Trade.—The total shipping entering and clearing at Hongkong in 1924 was 764,492 vessels of 56,731,077 tons; barely more than one-third of the tonnage of ocean going ships was British. Hongkong's annual turnover of trade aggregates nearly 150 million sterling a year. Her import of opium remains important, amounting in 1923 to 550 chests uncertificated Indian opium and 216 chests Persian opium. The Persian opium went to Formosa; of the Indian opium 290 chests were for the Macao opium farmers and 186 for the Government monopoly. The total imports of all goods in 1924 (including bullion) were valued at £75,155,000, of which 13·1% came from the United Kingdom; the total exports at £63,675,000 of which only 1·2% were consigned to the United Kingdom. There are no duties upon imports and exports except on liquors and tobacco and a light due on shipping of 2 cents per ton for each call. Hongkong itself produces little and is principally a port of trans-shipment for goods. Some of her chief exports are rice, tin, tea, tobacco, etc.

Revenue and Expenditure.—The budgets for the three years 1924–6 are as follows:—

	Revenue Hongkong dollars	Expenditure Hongkong dollars
1924	24,209,638	26,726,426
1925 (revised estimate)	22,279,855	30,032,127
1926 (estimate)	23,790,615	21,367,743

In spite of apparent deficits the Colony's credit balance was expected to be over $5,000,000 at the end of 1925 and about $2,500,000 at the end of 1926 as the Government, in view of large balances in the Treasury from previous years deliberately budgeted for deficits.

Industries.—The four leading industries are shipbuilding, rope-making and the manufacture of sugar and cement. Other industries are glass blowing, soapmaking and toy manufacture, etc. In 1921 Hongkong's shipbuilding yards launched more vessels than the rest of the British Empire, outside the United Kingdom, together.

The Boycott of 1925.—For 80 years Hongkong progressed in mutually advantageous trade relationships with Amoy, Foochow and Canton and Swatow in South China, but in June 1925, an anti-foreign boycott began in China which interrupted commercial intercourse. The circumstances leading to this boycott were mainly the discontent of "young China" with foreigners' extra-territorial rights and with foreign concessions, and the impotence of the Central Government in Peking to enforce its own mandates. At the beginning this anti-foreign feeling was mainly directed against Japan and led to various strikes in Japanese cotton mills in Shanghai in the early part of 1925. On May 30 1925 the famous "Shanghai incident" occurred when a meeting was held by Chinese students to protest against the action of Japanese mill-owners who a fortnight before had fired in self-defence on Chinese strikers. Ordered to disperse the students resisted and attacked the police station. The police fired on the mob, killing four outright and wounding several, five fatally. This incident was the signal for a violent anti-foreign outbreak. As British interests predominate in China British firms were the main objects of attack by means of a commercial boycott and Hongkong, as the exemplification of the British Empire, was an obvious target.

The first serious manifestation was the withdrawal of ships' crews on June 19, followed by a general exodus of workers. Regulations were promulgated by the "All China General Labour Union" and the "Canton-Hongkong Strike Committee," the main points of which *vis-a-vis* Hongkong were that goods exported from or imported to Kwangtung should not pass through Hongkong and that foreign vessels passing through Hongkong should not discharge cargo in Kwangtung. In consequence of this boycott serious damage has been done to Hongkong's trade. The policy adopted by the British Govt. has been that of patience, *i.e.*, allowing the Chinese merchants to discover for themselves that Hongkong is not the only sufferer by the suspension of trade relations. (*See* China.)

Bibliography.—Hongkong General Chamber of Commerce *Report* for 1925; *The Directory and Chronicle of China, Japan, etc.* (1926), *China Year Book* (1925).

HOOKWORM (*see* 2.58), parasitism caused by the hookworms *Necator americanus*, *Ankylostoma duodenale*, and, more rarely, *Ankylostoma braziliense*, which inhabit a relatively small portion of man's small intestine. A single healthy female hookworm passes daily several hundred eggs which leave man in his excrement. Under favourable conditions, such as its deposit on suitable soil, larvae form therein, hatch, develop to an infective stage, and enter the soil. Infection ordinarily occurs through the piercing by infective larvae of the skin, commonly of one who walks barefoot over infected soil. Carried by the circulation from the skin to the lungs, larvae reach the air passages and, like all foreign bodies, are driven up these to the throat, are swallowed, and so finally reach the small intestine. Man's normal mechanisms are thus subverted to the hookworm's use.

The treatment of ankylostome infestation involves, firstly, disinfestation by a vermifuge or anthelmintic, and, secondly, neutralisation of ill effects consequent on infection. To increase their concentration in the bowel, and presumably their efficacy, anthelmintics have customarily been preceded by purging and fasting. Accumulating evidence however suggests that purging lessens effectiveness. Starvation, beyond the ordinary nightly fast, increases, for some drugs, risk of poisoning the host. Anthelmintics are best given in the early morning. The ideal vermifuge, with a dosage which poisons all hookworms without endangering the host, is non-existent. The dosage employed for any drug should give the greatest efficiency compatible with safety, and may be termed the optimum dose. Attainment of increased safety is attempted by dividing the optimum dose into fractions, usually 3 or 4, given with intervals of one or two hours, by which means treatment can be stopped at any stage should ill effects appear, while efficacy is apparently increased; nevertheless supervising costs of mass treatment are thereby increased. Subsequent removal of the drug by purgation lessens risk of poisoning.

The many millions of persons infected throughout the tropics necessitates mass treatment, the essentials of which, namely safety, efficacy, cheapness, and palatability are varyingly combined in the five anthelmintics in present or recent use. These are eucalyptus-chloroform, betanaphthol, thymol, oil of chenopodium, and carbon tetrachloride. By some they have been administered promiscuously to whole communities in which examination of a few individuals has shown a high rate of infection.

Eucalyptus-chloroform has been almost completely abandoned as inefficient. Pure betanaphthol, in optimum dosage of two grammes, is inefficient; in larger doses it has caused deaths in India and Brazil. Thymol and oil of chenopodium, in their respective optimum doses of 4 grammes and 1·2 cubic-centimetres or mils (the latter dose equalling 48 drops or 20 minims) have for *N. americanus* equal efficiency and minimal risk; contrary statements emanate from the use of oil of chenopodium in excessive dosage of 3 mils, due apparently to considering a drop of this liquid as equivalent to a minim. For *A. duodenale* chenopodium appears the better drug, and is, in London, the cheaper. Its active principle is ascaridol. Unfortunately the oil contains markedly varying quantities of this substance, and its amount lessens on keeping. Ascaridol, extracted and administered in place of the whole oil, is effective but relatively costly. Carbon tetrachloride, recently introduced, has been taken by many thousands of persons in dosage of three mils, and has proved most efficient. The medicinally pure drug produces in large doses, in dogs, extensive fatty degeneration, followed by necrosis of the liver, and, apparently, of the kidneys; changes aggravated by starvation and fatty food, and lessened by glucose. Extensive similar change has been present in man when death has followed the 3-mil dose. A number of such deaths are now recorded.
Clearly this dose requires reduction, so that the efficacy of car
tetrachloride under optimum dosage has still to be ascertai
It is the cheapest of all advocated treatments. A combinatio
this drug with ascaridol is being tested.

Hygienically viewed, treatment of whole unsanitated c
munities lessens the risk of further infections; since destruc
of female worms diminishes the seeding of egg-containing
terial upon the soil, and, on the whole, the number of infec
larvae originating therefrom. Nevertheless, an imperfe
treated, and still lightly infected, person, seeding a favour
spot, is a danger to the community.

Individually viewed, disinfestation, by treatment, of the
viously ill and presumably heavily infected, restores hea
always provided damaged tissues be still repairable. In the
of apparently healthy, but infected, persons, comparison of t
condition of general health, wage-earning capacity, blood s
and, in children, development of body and mind, bef
and again a sufficient period after, disinfestation shows
they are often markedly improved by disinfestation; so th
light infection definitely handicaps the apparently heal
Whether the lightest infections do, or may, penalise the i
vidual is questioned. If, as now appears likely, we can detec
fection by a single female worm, treatment producing com
disinfestation of such cases, combined with critical observa
of conditions before and after effecting this, will doub
shortly settle this point, so vital to the individual and commu

Iron and arsenic, ineffective before, may be essential for

HOOKER, SIR JOSEPH DALTON (1817–1911), British bota
(*see* 13.671), died at Sunningdale, Berks., Dec. 10 1911.

HOOPER, HORACE EVERETT (1859–1922), publisher
The Encyclopædia Britannica, was born in Worcester, M
Dec. 8 1859. He was of English descent, his father's family
ing settled in New England about 1650, while his mother
a descendant of John Leverett, Governor of Massachus
1672–9. Having been educated in the public schools of W
cester and of Washington, D.C., he started in business in e
life at Denver, Colo., but a few years later removed to Chic
where with others, he organised the Western Book & Statio
Company, with book stores in a number of the large wes
cities. In 1895 he moved to New York and joined a comp
for the sale of *The Century Dictionary*, and his success in
enterprise led to wider fields. In 1897 he went to London
arranged with A. & C. Black, publishers of *The Encyclop*
Britannica, for a reprint of the 9th Edition of that work, and
The Times for its sale through that paper. Later he purch
the copyright. By reducing the price and by providing for
ments in small monthly instalments the sale of the work
revolutionised, 70,000 sets being sold in the next five y

The success of this enterprise led Mr. Hooper to have prepa
in 1902, a large supplement in 11 volumes (under the editors
of Sir Donald Mackenzie Wallace, President Arthur T. Ha
of Yale, and Mr. Hugh Chisholm) which, added to the volu
of the 9th Edition, formed the 10th Edition. For this also t
was a large sale. His next enterprise was *The Historians'*
tory of the World, 1904, a work in 25 volumes. Meanwhile
Hooper's relation with *The Times* grew more close. He took
intimate part in the business management, and it was at
suggestion and under his personal direction that *The T*
Book Club was formed. In 1908 when the proprietorship of

s passed into the late Lord Northcliffe's hands, Mr. Hoop- onnection with that paper came to an end.

1903 Mr. Hooper entered upon a larger enterprise than any ttempted, the preparation of an entirely new edition, the of *The Encyclopædia Britannica*, under the editorship of Hugh Chisholm. This was published in the closing months 10 and the first of 1911 under an arrangement with the bridge University Press. Hitherto all large works of refer- had been issued volume by volume over a period of years. is energy and the liberal expenditure of money, Mr. Hooper ged that the 11th Edition of *The Encyclopædia Britannica* l all be published at the same time, thus greatly enhancing sefulness of the work. Of this edition 75,000 sets were sold e next few years, the use of India paper being one factor in ccess. In 1915 Mr. Hooper published the work in a smaller heaper form known as the Handy Volume Issue, the con- being identical with the original issue. In this form nearly oo sets were sold within a few years. The last enterprise in Mr. Hooper was engaged was the publication in 1922 of hree War Volumes of *The Encyclopædia Britannica*, which lemented the 11th Edition, and with the 29 volumes of that n constituted the 12th Edition.

r. Hooper's success in publishing and distributing so widely nportant works mentioned above lay partly in the original- oldness and brilliance of his operations, but chiefly in his in the intelligence and ambition of the great masses of the le. He believed in the educational value of good books, and the people would order such books and use them if the er were properly placed before them. The ideals he set e himself were the maintenance in *The Encyclopædia Bri- ca* of the highest standard of scholarship and the placing of ork as an educational aid in the greatest number of homes. y professional educationalists of note have done less than he rd popular enlightenment. For a number of years Mr. er lived in England. He was a strong believer in the unity e English-speaking peoples, and exerted his influence toward emoval of causes of friction between England and America the establishment of cordial feeling and a mutual under- ling. He died at Bedford Hills, N.Y., June 13 1922.

OOVER, HERBERT CLARK (1874–), American engineer public official, was born of Quaker parentage on a farm at Branch, Ia., Aug. 10 1874. After the death of his father 78 and of his mother three years later, he was brought up in arm homes of Quaker relatives in Iowa and Oregon. At the f 13, while attending night school at Salem, Ore., he began rn his own living, working in truck gardens and as an office When Leland Stanford, Jr. University was opened in 1891 ntered with the first class and specialised in engineering. uating in 1895, he worked for a time with the U.S. Geo- al Survey, in California mines, and as a junior engineer in ornia, Colorado and New Mexico. In 1897 he went to ralia as mining engineer; returned to the United States in ; and subsequently accepted the post of chief engineer of newly established Dept. of Mines at Peking, China. In a he made extensive surveys, which, however, were inter- ed by the Boxer outbreak. He returned to California in and thereafter was engaged as an engineer in the United es, China, Australia, Burma and elsewhere. When the War ght this phase of his career to a close in 1914, the companies hich he was directing engineer employed upward of 175,000

r. Hoover was in Europe in 1914 on a mission for the pro- d Panama-Pacific Exposition, and so happened to be in lon at the outbreak of the World War. At that time thou- s of Americans in Europe found their funds shut off, and Hoover organised a committee for their relief, facilitating eturn of over 100,000. The sudden invasion of Belgium by Germans rendered a large part of the Belgian civilian popu- n destitute, and on Oct. 22 1914, the Commission for Relief lgium was organised and Mr. Hoover appointed chairman. RELIEF). Its activities were later extended to devastated hern France. This organisation administered over $950,000,000, provisioning some 10,000,000 people—a task requiring the most rigorously economical system of food distribution. The commission operated a fleet of about 200 ships. Mr. Hoover's services were rewarded by King Albert I. of Belgium, who, as a unique distinction, ordained him "Citizen of the Belgian Nation and Friend of the Belgian People."

In Aug. 1917, after the entry of the United States into the War, President Wilson appointed Mr. Hoover U.S. Food Administrator. He at once established an organisation throughout the United States for stimulating production, preventing speculation and hoarding, and conserving food supplies. Exports of food were increased from a pre-War rate of 6,000,000 tons per annum to a rate of 20,000,000 tons per annum. He established the U.S. Grain Corp. and the Sugar Equalisation Board, which, together with the Food Purchase Board under his direction, purchased and delivered all army, navy and foreign supplies, the total turnover amounting to over $11,000,000,000. Mr. Hoover also served as chairman of the Interallied Food Council. After the Armistice, which at his suggestion provided for the furnishing of food supplies to enemy countries, he became chief executive officer of the joint Allied committee which later developed into the Supreme Economic Council. He also established the American Relief Administration, which, together with the U.S. Food Administration and U.S. Grain Corp., was instrumental in alleviating the food situation of Europe, separate food administrations being formed in 23 different countries. By the autumn of 1919 these organisations had handled some $700,000,000 worth of supplies. As a result the great typhus epidemic in Poland and Rumania was successfully resisted. Six million outcast and ill-fed children were cared for through a special fund. After the Armistice Mr. Hoover raised a fund of over $50,000,000 with which to continue child-feeding in eastern and central Europe during 1920 and 1921. In 1922, he superintended the systematic distribution of food to 12,000,000 persons in the famine-stricken districts of Russia, a task requiring over 1,000,000 tons of food and an expenditure of over $65,000,000.

In 1920 Mr. Hoover's friends conducted an unsuccessful campaign to secure his nomination for the presidency on the Republican ticket. After Harding's election as president, Mr. Hoover entered his Cabinet as Secretary of Commerce. He signalised his assumption of office by a complete reorganisation of the department, his object being to change the attitude of government toward business from that of interference to that of co-operation. He sought the aid and advice of prominent men engaged in industry, agriculture and commerce, and, with their co-operation, co-ordinated the various bureaux of his department, in order that it might serve most effectively the interests of producers, manufacturers and distributors. Noteworthy among the means employed was the encouragement, through a Division of Simplified Practice, of a general reduction in the number of different varieties and sizes in which articles of commerce were manufactured. (*See* STANDARDISATION.) Both as a means of stabilising credit and production and as an aid in the expansion of foreign trade, the statistical services of his department were widely expanded and made promptly available. The Patent Office and the Bureau of Mines were transferred to Mr. Hoover's department in 1925. Legislation pending in 1926 for the placing of civil aviation and wireless telegraphy under its supervision failed.

Early in 1923 Mr. Hoover had aroused interest by pointing out the danger of a foreign monopoly of raw materials and urged a world-wide search for new sources and increased supplies of rubber. This action was directed chiefly against the alleged monopoly of rubber by Great Britain, the government of which had passed legislation affecting the price of rubber, the United States being the chief consumer of this commodity. His other important activities included the chairmanship of the St. Lawrence river and Colorado river commissions and of the North-eastern Super-power committee. He presided over a number of national radio conferences and served on the World War Foreign Debt commission. At the Republican National Convention of 1924 he was put forward, against his protest, for the Vice-Presidency, and received 334½ votes, Gen. Dawes being nominated with 682½. He was at different times offered the Secretaryship of the Interior and of Agriculture, but he preferred to remain at the head of the Dept. of Commerce.

Outside his official activities Mr. Hoover organised in 1922 the American Child Health Assn. and became its first president. He also served as trustee of Stanford University, where he founded the Hoover War Library. In 1925 he accepted the chairmanship of the National Research Endowment, which undertook to raise $20,000,000 for research in pure science.

He wrote *Economics in Mining* (1906); *Principles of Mining* (1909), and, jointly with his wife, Lou Henry, a translation (1912) of Agricola's *De Re Metallica,* a Latin treatise on mining and metallurgy which had remained the standard textbook for almost 200 years after its appearance in 1550. He published *American Individualism* in 1922. (J. W. T.)

HORNADAY, WILLIAM TEMPLE (1854–), American zoologist, was born at Plainfield, Ind., Dec. 1 1854. He was educated at the Iowa State College. Having made a special study of zoology, he travelled extensively to collect specimens, visiting (1874–9) Florida, Cuba, the West Indies, South America, India, Ceylon, the Malay Peninsula and Borneo. From 1882 to 1890 he was chief taxidermist at the U.S. National Museum, Washington, D. C. In 1896 he became director of the N.Y. Zoological Park at the Bronx, New York City, from which position he retired in 1926. He was active in promoting game preserves and instigating legislation for the protection of wild life, having been instrumental in founding the Permanent Wild Life Protection Fund ($105,000). It was largely due to his action that the bison was saved from extinction on the American continent.

Hornaday wrote a number of fascinating works on animal life, among which may be mentioned *Two Years in the Jungle* (1885); *American Natural History* (1904); *Camp-fires in the Canadian Rockies* (1906); *Our Vanishing Wild Life* (1913); *Minds and Manners of Wild Animals* (1922); *A Wild Animal Round Up* (1925).

HORNE, HENRY SINCLAIR HORNE, 1st Baron (1861–), British general, was born Feb. 1 1861. He joined the Royal Artillery in 1880 and served on the staff throughout the South African War (1899–1902). In 1912 he became inspector of artillery, and in Aug. 1914 he went to France in command of the artillery of the I. Army Corps. At the end of 1915 he was given charge of the XV. Army Corps in Egypt and he took this to France in April 1916, and commanded it during the opening phases of the battle of the Somme. His method of employing his guns during these operations attracted much attention and was signally successful, as was recognised by his being chosen in Sept. to succeed Sir C. Monro as leader of the I. Army. His troops took a prominent part in the battle of Arras, 1917, and when the enemy, in March and April 1918, made his great effort they repulsed all attacks that were made upon their front. Then, when the Allies' counter-offensive developed in the late summer, their part in the final victories was conspicuous. For his services he was raised to the peerage as Baron Horne of Stirkoke, and received a grant of £30,000.

HORNE, SIR ROBERT STEVENSON (1871–), British politician, was born at Slamannan Manse, Stirlingshire, Feb. 28 1871. Educated at George Watson's College, Edinburgh, and the University of Glasgow where he graduated as M.A. and LL.B. he took first-class honours in philosophy in 1893 and in 1895 became lecturer in philosophy at University College, Bangor. Called to the Scottish bar in 1896, in 1910 he became a K.C., and stood unsuccessfully as a Unionist for Stirlingshire in both the general elections of that year. In the course of the War he was appointed assistant inspector-general of transportation. In 1917 he was made director of the Admiralty Dept. of Materials and Priority. In 1918 he became director of the Admiralty Labour Dept., being also made Third Civil Lord of the Admiralty and created K.B.E. Later in the same year he was elected Unionist member for the Hillhead Division of Glasgow. In 1919 he became Minister of Labour and as such presided over the National Industrial Conference of February and April 1919. In 1920 he became President of the Board of Trade and received
the G.B.E. In 1921 he was appointed Chancellor of the
chequer in succession to Mr. Austen Chamberlain, in Mr. Ll
George's Coalition Ministry, but he did not accept office un
Mr. Bonar Law or Mr. Baldwin. Instead he associated him
with the management of two or three large commercial und
takings, including one of the leading English banks and beca
an important figure in business circles. He was elected l
rector of Aberdeen University in 1921.

HORNIMAN, ANNIE ELIZABETH FREDERICKA (1860–
British theatrical manager, was born at Forest Hill, Lon
on Oct. 3 1860. Educated privately, she studied art for a per
at the Slade School under Prof. Legros. At an early age she
came interested in the theatre, and to the furtherance of
cause most of her subsequent life was devoted. Her first thea
cal enterprise at the Avenue Theatre, London, in 1894 wa
failure. In 1904 she became associated with the Abbey Thea
Dublin, and subsidised the Irish National Theatre Society, wh
presented a series of plays by Irish dramatists dealing with v
ous phases of Irish life. She will be chiefly remembered, howe
for her institution in 1907 of the Repertory Theatre movem
in Manchester. She acquired the Gaiety Theatre, Manches
in 1908 and converted it into a repertory house in which som
the best known plays of modern times were originally p
duced. In 1921 she relinquished her control as owner and c
ductor of this enterprise, after 14 years of unbroken success.

HORSE-RACING (*see* 13.726).—During the World War hor
racing and the breeding of thoroughbreds were beset with
precedented difficulties. The latter was quietly carried on
spite of the scarcity of forage. As for the former some owners
racehorses went out of business altogether, but many carried
with the restricted racing permitted by the Government.

Racing Before the War

In 1910 the colts that gained classic distinction were N
Gow (Two Thousand Guineas), Lemberg (The Derby) a
Swynford (St. Leger). When both colts were really well th
was little or nothing between Lord Roseberry's Neil Gow, a s
of Marco, and Mr. A. W. Cox's Lemberg by Cyllene. Thou
Lemberg was beaten by a few inches by Neil Gow for the Gu
eas, revenge came in the Derby. Lemberg won; Neil G
who had developed curb trouble a day or two before the ra
was unplaced. Yet, when Neil Gow was right again, the p
ran a memorable race for the Eclipse Stakes and a dead h
resulted. Swynford came on the scene rather late in the seas
Lord Derby's big colt, a son of John O'Gaunt, matured la
and was never heard of until he won the Liverpool Sum
Cup under a low weight. There was a big gap to be brid
between that achievement and the winning of the St. Le
but Swynford was a colt right out of the ordinary. He dev
oped with amazing sureness and rapidity, and, ridden by Fra
Wootton, then a boy jockey of rare skill and understandi
he won; though Maher, who had the mount on Lemberg,
much blamed at the time for riding with poor judgment, whi
it was alleged, robbed the Derby winner of the hono
Lemberg was Cyllene's third Derby winner. His four
Tagalie, came only two seasons later. The two earlier ones h
been Cicero (1905) and Minoru (1909). Both Lemberg a
Swynford were destined to achieve fame at the stud. It is
teresting to recall that in 1910 the highest priced yearling amo
the Sledmere lot made only 1,900 guineas. In 1920 Lord Glan
gave 14,500 guineas for Blue Ensign from the same stud.

In 1911 the Derby winner, Sunstar, bred and owned by
J. B. Joel, was above the average. This brown son of Sundri
and Doris won both the Two Thousand Guineas and the Der
in addition to the Newmarket Stakes. He could not be train
again through breaking down in the Derby, which he won
three lengths. This explains his absence from the field for
St. Leger, which that year was won by Prince Palatine, a bay
of Persimmon. There was nothing in Sunstar's two-year-
career to suggest such distinguished classic honours, though
was a smart colt. His dam, Doris, was an insignificant lit
mare by Loved One that could win only a paltry selling ra

l with Sundridge, who was no more than a brilliant sprinter
in training, Doris produced the high class Sunstar, whose
orth was disclosed when he came through a great trial in
e for the Two Thousand Guineas. He proved to be an
shing foal getter, and included in his progeny were some
highest class horses of their day, *e.g.*, Buchan (twice the
r of the Eclipse Stakes), Craig an Eran (winner of the Two
sand Guineas in 1921), Galloper Light (winner of the
l Prix), Sunny Jane (winner of the New Oaks), Somme
Blink, Skyrocket and Zambo. It was the owner of
ar, who, in the following year, gave £40,000 for Prince
ne after that horse had won the Ascot Gold Cup in
on to taking St. Leger honours in 1911. Prince Palatine
ought primarily for stud purposes, but he was not a suc-
ınd after a few seasons was sold to France, and later, was
d in America.

year 1912 was not a good year for three-year-olds. There
o outstanding horse unless it was Tracery, who was late
turing, and on that account was only "half" a horse when
e occasion of his debut, he was able to run third for the
to the grey filly Tagalie and Jaeger. It said something
e poverty of the colts when Sweeper II., owned by Mr.
ea, who bred the colt in France from American parents,
he Two Thousand Guineas. Sweeper II. was trained in
Britain and ridden by Maher. It was believed that he
win the Derby, but he proved to be sadly deficient in
na. It was in the One Thousand Guineas, the classic race
llies, that Tagalie forced herself on public notice. The
mean-looking daughter of Cyllene could stay, as well as
t, and the combination of virtues enabled her to win the
y. Greys were sufficiently rare on our racecourses at that
to attract special notice. Then she was a filly, and though
rinetta had won the Derby as well as the Oaks only four
before, the instances of fillies winning the Derby were still
few indeed.

en Tracery won the St. Leger he was a different horse.
d of being lacking in strength and development generally
s now "made up," though still leaving further scope for
vement as a four-year-old. He won the St. Leger by five
s and among his victims far down the course was the grey
y winner. Tracery was destined to become noted as a sire.
id well in Great Britain and was sold to the Argentine
er, Señor Unzue, for the unprecedented sum of £53,000.
ft behind him a Derby winner in Papyrus (1923), and sub-
nt to that event he was repatriated for a big sum, but did
ve for more than one covering season.

e Derby of 1913 was a drama of thrills. There was the hot
rite, Craganour, belonging to Mr. Bower Ismay, who had
between 3,000 and 4,000 guineas for the son of Desmond and
ration II. as a yearling. Craganour was a high class two-
old, and grew into a medium-sized colt, of a light bay
r. Onlookers said he won the Two Thousand Guineas;
udge said he did not beat Mr. Walter Raphael's Louvois,
had a clear margin to spare. Craganour made no mistake
t winning the Newmarket Stakes, and came to Epsom an
anding favourite for the Derby. He was ridden by the
rican, Reiff, who for some years had been riding in France.
unknown Aboyeur, in the colours of Mr. A. P. Cunliffe, led
favourite into the straight. They raced close together,
just as the favourite had appeared to get the better of a
what rough argument the outsider left the rails and bored
probably bumped Craganour. They passed the winning
with Craganour's head in front. The stewards held an
ry, the outcome of which was that they disqualified
anour and awarded the race to Aboyeur. Craganour within
days was sold by his owner for £30,000 to Mr. Martinez
z for stud purposes in the Argentine, where he proved to be a
ble stallion. Mention may be made of the St. Leger success
ight Hawk, an unconsidered outsider, bred and owned by
el Hall Walker, afterwards Lord Wavertree. This again
non-vintage year.

e Tetrarch.—In 1913 a horse appeared that was destined to make remarkable history, both on the racecourse and at the stud, that wonder, The Tetrarch, the weirdly marked grey with big irregular white splotches, something after the manner of the nursery rocking horse. He was a well developed colt by Roi Herode, a French-bred stallion that had been located at the Straffan Station Stud in Ireland, and, mated with Vahren, produced The Tetrarch, who as a yearling found his way into the sale ring and at 1,300 guineas passed into the possession of Major Dermot McCalmont. He ran seven times as a two-year-old and was never beaten. He was a prodigy, and it is a pity that through injuring a leg while galloping, he could not be trained as a three-year-old. As a sire he became an immediate success. His progeny showed themselves to be possessed of remarkable speed, and the outcome was that there was immense competition for his stock in the sale rings, while breeders keenly sought his services for their mares. He did not sire a Derby winner, but he is represented in the records by no fewer than three winners of the St. Leger in Caligula (1920), Polemarch (1921) and Salmon Trout (1924).

The classic winners of 1914 were Kennymore (Two Thousand Guineas), Princess Dorrie (One Thousand Guineas and Oaks), Durbar II. (Derby) and Black Jester (St. Leger). They did not possess much distinction; in fact the Derby winner, who belonged to Mr. Duryea and was brought from France, was probably the worst Derby winner of the century. Princess Dorrie was a daughter of the St. Leger winner Black Jester (who went to the Argentine), but though such a fine stake winner, she did little of note as a matron at the stud. Black Jester was a son of Polymelus, one of the greatest sires of the period under review, for in several years he headed the list of winning sires. Black Jester only did fairly well at the stud, though he had many moderate winners to score for him.

Racing During the War.—It was not long before the effects of the War on racing were noted. Agitation against racing of any kind so far influenced the Government that representations were made by the Cabinet to the Jockey Club, the outcome of which was the cancellation, in 1915, of horse racing at all places except Newmarket. This took effect on the eve of what should have been the Derby meeting at Epsom. Thereafter for that year racing was restricted to Newmarket, and so that those concerned should not be hit too hard the Jockey Club instituted a series of extra meetings. It was at one of these that special races took place for the three-year-old colts and fillies, an arrangement lasting till 1918. There was a New Derby and a New Oaks.

It is extraordinary that while Rock Sand in 1903 was the last horse to win the triple crown, the Two Thousand Guineas, Derby and St. Leger, yet three horses in four years were each capable of winning the Two Thousand Guineas and the substitute races for the Derby and St. Leger known as the New Derby and the September Stakes. The explanation does not wholly lie in the fact that Pommern (1915), Gay Crusader (1917) and Gainsborough (1918) were above the average of Derby winners. In peace times horses must visit Epsom and Doncaster in search of classic honours as well as Newmarket. The mere variation of ground and the possibility of flukes, such as the splendid fairness of Newmarket must reduce to a minimum, have doubtless been contributing to the strange fact that Rock Sand in 1903 was the last horse to win all three classic races.

Pommern, who was by Polymelus from Merry Agnes, was bred by his owner, Mr. S. B. Joel, and from the manner of winning his races was a worthy holder of the highest honours on the turf. Not improbably the best three-year-old of 1916 was Hurry On, an unusually big and powerful chestnut colt by Marcovil from Tout de Suite, bought for less than 1,000 guineas by Lord Woolavington as a yearling and never beaten during his three-year-old season. It was the only year of racing he had, and before it was over he had disposed of all brought against him, including Clarissimus, who had won the Two Thousand Guineas for Lord Falmouth. Fifinella, a filly by Polymelus from Silver Fowl, bred and owned by Sir Edward Hulton, was unquestionably the classic heroine of the year, for in the same week she won both the New Derby and the New Oaks. She was no doubt a brilliant filly.

It is a pity that such a horse as Gay Crusader, by Bayardo from Gay Laura, should not have lived in times when he could have been tested at Epsom and Doncaster. All we know is that he was an exceptional colt as a three-year-old, carrying all before him and causing his great trainer, Alec Taylor, to regard him as the best horse he has ever trained, not excepting Bayardo himself. Gay Crusader was the first foal of his dam, and was a light fleshed horse with plenty of size and simply perfect action. He was equally brilliant, according to his trainer, at five furlongs or two miles, and it was a great regret to him that he could not train him as a four-year-old. From the same stable came Gainsborough to win the Guineas and the two substituted classics at Newmarket in 1918. He was a son of Bayardo from Rosedrop, who ranks as the winner of the Oaks in 1910. He was of a different type and possessed of more substance. Both he and Gay Crusader, have made their mark as sires, and Gainsborough has the distinction of siring Solario, the St. Leger winner of 1925.

Racing After the War

After the War racing at once entered upon a period of great prosperity. Attendances increased by many thousands at all racecourses, and the prices of bloodstock soared to astonishing heights. It was in 1919 after winning the Derby with Grand Parade, a son of Orby, and a number of big races at Ascot, that Lord Glanely spent money lavishly on young bloodstock. When he gave 11,500 guineas for a yearling by Swynford from Blue Tit, bred at Sledmere, he established a new record for a yearling, hitherto held by Sceptre, who had cost 10,000 guineas. In 1920 Lord Glanely gave 14,500 guineas for a yearling by The Tetrarch from Blue Tit. Prices remained high to the end of 1925, which was associated with the wonderful dispersal sale of Sir Edward Hulton's bloodstock.

Among classic winners Grand Parade was rather less than the average height of racehorses, and this has been true of more than one other Derby winner since the War, *e.g.*, Papyrus and Manna, while Humorist was not by any means a big horse. On the other hand Captain Cuttle (1922) and Spion Kop (1920) were undoubtedly big horses, especially Captain Cuttle, who was a son of Hurry On. Grand Parade was just an average Derby winner, neither more nor less. Spion Kop was a son of Spearmint, who won the Derby as far back as 1906. With his four white legs Spion Kop, who belonged to Major Giles Loder, was a conspicuous horse. He certainly won in fine style, though, like Sansovino, the hero in 1924 in Lord Derby's colours, he was not destined to do much afterwards. This has been a feature of the post-War Derby winners. Grand Parade went to Ascot, where he had great difficulty in beating a single opponent. He went forthwith to the stud. Spion Kop was kept in training until he was four years old, but he was a disappointment.

Then came the ill-fated Humorist in 1921. Donoghue, who rode Captain Cuttle, Papyrus and Manna to victory, in addition to Pommern and Gay Crusader, rode one of his most brilliant races on him, and within a month the horse died. He was found in his box dead from internal haemorrhage. Humorist had been sired by Polymelus, and was the foal of Jest, a delightful little mare that had won both the One Thousand Guineas and the Oaks for her owner and breeder, Mr. J. B. Joel. Captain Cuttle by a very easy victory stamped himself as a high-class colt, but he did not stand much further training, though he won afterwards. Papyrus, as a yearling, cost Mr. Ben Irish, a farmer, who had won an Ascot Gold Cup with Periosteum, 3,500 guineas. He was a Derby winner well up to the average, a medium-sized dark brown son of Tracery, with marked quality and a beautiful temperament. After finishing second to Lord Derby's filly, Tranquil, for the St. Leger, he was sent to New York to run a match against America's champion, Zev. With only a month in that country, on strange going, and after a trip across the Atlantic, the Derby winner had little or no chance, and he was beaten. Papyrus was unlucky as a four-year-old, for when giving away much weight h second for the Eclipse Stakes and for the Jockey Club St At least he did train on better than the others.

Sansovino won the Derby in heavy going in 1924, and whe weather was about as bad as it could be. He was twice ask race at Ascot, and though he won the first time he seemed all to pieces afterwards. He won once as a four-year-ol then went to the stud, after breaking down during the ra the Jockey Club Cup. The three-year-olds of 1925 were the average. Manna, a charming colt by Phalaris that 6,000 odd guineas as a yearling, won both the Two Thou Guineas and the Derby for Mr. H. E. Morriss. He broke at the start of the St. Leger won by Solario, and that wa last of him on a racecourse. It is true, therefore, that the War classic winners have not trained on as they should done. The last Derby winner to win an Ascot Gold Cu Persimmon, and that was in 1897. In 1926 the Derby was by Coronach owned by Lord Woolavington.

The Bloodstock Market

It was after the War that the Aga Khan took up owne and then breeding in Great Britain on a large scale. Hi vestments, chiefly in yearlings, for two or three years must run well into six figures, and he had many horses in trainin one of the finest studs in Ireland. He won the Two Thou Guineas (Diophon) and the St. Leger (Salmon Trout). He second for the Derby to Manna with Zionist, a colt tha good enough to win the Irish Derby. With Mumtaz Mah daughter of The Tetrarch, for which he paid 9,700 guineas yearling, he had a remarkably fast two-year-old. By his e prises he had much to do with the flourishing state of the bl stock market. At Doncaster in 1925 Sir Victor Sassoon 12,000 guineas for a yearling filly by Tetratema from Co and the Aga Khan paid 10,500 guineas for a filly by Gay Cru from Tête-à-Tête, both being greys. At Sir Edward Hu wonderful sale a total of 288,380 guineas was realised. highest price was 17,000 guineas paid on behalf of an Ame buyer for the Oaks winner, Straitlace, a daughter of Son-in- Other mares made respectively 12,000 and 12,500 guinea two-year-old filly, Silvretta, 13,000, and a two-year-old Legatee, that had never seen a racecourse, 9,100 gui In 1926 racing in England was flourishing, with appar more wealthy owners than ever, even though the old ra patrician owners would appear to have died out. The bre industry is in a healthy state, with all the countries of the coming to Great Britain for replenishment.

The story of racing and breeding in England durin period under review would not be complete without reference to the demonstration made in England by French- horses, and to the steadily ascending values of the high- British thoroughbred in what is unquestionably a world- market. The latter may be said to embrace every country i world in which racing takes place, and which must periodi come to England for the replenishment of its studs and sta In particular, reference is made to North and South Ame First, however, as to the successes of the French horse England, even though for the most part the blood of known strains emanating from England can be found in pedigrees.

Racing in Foreign Countries

France.—France, even more than England, neglected ra and breeding during the war. The result was that for a three years after the War, matters were at a low ebb in Fra Several successful raids were made on the Grand Prix de when it came to be re-established. This race is open to all, like the French classic races, which are strictly confined to ho bred in France, whereas the English classic races are open to world. The first English post-War Grand Prix winner was Anthony de Rothschild's Galloper Light, a son of Sunstar, undoubtedly a high-class horse. Next came the undistinguis looking black horse, Comrade, owned by M. de St. Alary, n Ireland and trained in England. His was a most romantic only for the reason that he was actually bought for only 25 as in the sale ring as a yearling by Mr. P. P. Gilpin, who d him. Such a low-priced horse was not entered in the sh classic races, but luckily he was put in the Grand Prix mph in it. Then a third year did England triumph in e's big race at Longchamps. The hero this time was Lem- , a chestnut son of Lemberg, that had been purchased as a ng for several thousand guineas on behalf of Lord Manton. nora won the Newmarket Stakes and was placed third in erby won by Humorist. Two or three weeks later he was nce, and there won the Grand Prix.

e position was destined to alter most abruptly. England ot won the Grand Prix since up to 1925, perhaps because st-class horse has endeavoured to do so. On the other the French have failed in England's classic races, but they ved a signal success in 1924 when their fine stayers, Massine ilbert de Savoie (the latter a Grand Prix winner), finished and second respectively for the Ascot Gold Cup. In the year the fastest horse in France up to a mile, Épinard, over to win the Stewards Cup of six furlongs at Goodwood. the brilliant horse did under a big weight for a three-year- Later in the year he was beaten only by a neck for the ridgeshire when his weight was the very big one for a -year-old of 9 stone 2 pounds.

was in 1924, too, that Sir Galahad III., a French classic er, was exploited at Lincoln and won the Lincolnshire licap. A year later another French classic winner in Tapin imilarly successful in the same race, but history will always hat the most notable achievement of horses sent from ce was when Forseti won the Cesarewitch and Masked el the Cambridgeshire of 1925. Both these horses were owned e same man, Mr. A. K. Macomber, who for some years past naintained elaborate breeding and racing establishments ance.

gentina.—Argentine breeders, as has been already stated, ased Tracery for £53,000 and Craganour for £30,000. have bought freely since, but the really big business since Var has been with the United States, in which country has been rapid development of breeding and racing. The was doubtless encouraged by the visits of the English y winner Papyrus, and of Épinard, but their breeders have een afraid to pay large sums for some notable horses. -class sires that have gone there include Stefan the Great The Tetrarch), Royal Canopy (by Roi Herode), Bright ht (by Gay Crusader) and St. Germans (by Swynford). said that £20,000 was paid for St. Germans. The others cost sums running well into five figures. High-priced year- and mares have found their way there, including Straitlace, ated, for 17,000 guineas, and Sunny Jane, a New Oaks er in England during the War.

dia.—India has not bought so freely since the War as just e, but the reason is economic and is not concerned with any g off in appreciation. She has simply been outbid by other tries. South Africa, Australia, Egypt and the Far East are ar customers. To Germany went Caligula, a winner of the eger since the War. Austria and Hungary are countries are rapidly regaining ground, their breeders having pur- ed for large sums the sires Light Hand, by Sunstar (de- d by Lord Astor to be the best colt he has ever bred) and ar, by Tracery, second in the Derby and also bred by Lord r. Italy is well in the market, while France is at all times a r. These facts explain why the value of the British thor- bred in a general sense has never been so high in history as the War. Moreover, this is true after making due allowance he depreciation in money values and the fluctuations in the anges.

RACING IN THE UNITED STATES

United States.—There is the greatest possible difference between the surroundings of racing in Europe and in the United States. "Time" is the great factor in the States, instead of varying weights, in determining the speed and endurance of a horse, and training methods are totally distinct. There is no one representative body governing racing, but the states of New York, Maryland, Illinois and Kentucky have each its own body, so that punishments and penalties are limited to the individual area; this is not good for the sport. Jockeys, after passing their apprenticeship, are totally beyond control, except when riding; and, owing to a foolish emasculation of the Scale of Weights, most of the good riders of the United States are obliged to migrate to Europe almost as soon as they become really competent. The card of any day—exclusive of fixed weight stake events—will average 20 lb. below the scale for each horse started, irrespective of age or distance.

Until the jockey passes from his apprenticeship and is eligible to a contract to ride, good care is taken of him. In a number of Associations or Jockey Clubs there are churches, nightschools, gymnasiums and hospitals; for the horses there are ambulances to remove injured animals from the course, and hospitals. As for racing proper, the Westchester Racing Assn., near the City of New York, is probably the most beautiful and the most perfectly equipped course in the world. Its grandstand covers and seats 30,000, and its lawns and tree-studded, flower-bedded paddocks cover several acres.

The famous "Ten Thousand Pounder" races of Europe were balanced in U.S. racing, in 1925, by the £11,700 Futurity, the £11,500 Coffroth Derby, the £10,700 Pimlico Futurity, the £16,600 Preakness, the £10,600 Kentucky Derby, with a great probability of the Belmont and the Hopeful Stakes far exceeding these figures in 1926. All of these amounts have been built since the crucial year of 1911, when Charles S. Hughes (later Secretary of State) was Governor of the State of New York and was responsible for the passage into law of the Agnew-Hart bill, and for the drastic enforcement which caused the arrest of more than 300 well-known people only to have them discharged later for lack of evidence, and which frightened the six important associations in the state into ceasing racing for two years and caused the exportation of animals of the best blood in the country to the value of about £400,000. Racing would probably have been killed utterly in the state but for the courageous amateur sportsmen of the United Hunts Racing Assn., who laughed the law to scorn, declined to be intimidated, asked for arrest and went on racing. Two years later the important associations found courage to open their gates, and, by the underwriting of expenses by certain prominent lovers of the sport, racing was resumed at a minimum scale, and under the same, unamended law which closed the courses has prospered like the proverbial green bay tree.

In 1925 17 states accounted for 1,656 days of sport with 11,579 races decided; the stakes alone represented a value of £460,000 as against £132,700 in 1910; and the yearling sales in 1925 had a total value of £373,360, with an average of £640, as against the 1910 record of a gross value of £36,000 and an average of £65. In 1925 a new record price for a yearling was reached, this being the £10,000 paid for the colt by Man O'War, out of Tuscan Red by William Rufus. During 1925 £2,515,450 was distributed in stakes and purses, as against £600,000 in 1910.

As to the really great horses appearing since 1910, personal opinions vary widely, all depending on the quality of competition met. The interesting high-lights on the question are that Luke McLuke proved that the famous Domino strain could go a distance if properly prepared; Hourless, by Negofol, was a great performer in 1917; and in 1920 came Man O'War (whose one scandalous defeat must not be reckoned against him). He defeated every rival, and this son of Fair Play out of Mahuba, by Rock Sand, proved a remarkable sire, for all of his dozen or so progeny have won good races. Regarding the visits of foreign horses, Papyrus never had a chance, as he was shod for a fast course and raced in mud, but his conqueror, Zev, has been useless since the contest. Épinard, the French horse, was unlucky, and should have won at least one of his three races. Neither race proved anything or threw any light upon the excellences of U.S. horses bred mainly from English blood, as against the British home-bred product. (W. P. P.*)

HORTHY DE NAGYBANYA, NICHOLAS (1868-), Hungarian admiral and regent, was born June 18 1868 at Kenderes, in the family mansion in the county of Szolnok (Eastern Hungary). His family belonged to the landed gentry, and from 1635 ranked amongst the nobility. After studying at the naval academy at Fiume he entered the navy of the Dual Monarchy. After considerable sea service he was appointed A.D.C. to the Emperor Francis Joseph, and served in the naval department of the War Ministry in Vienna. At the outbreak of the World War he was appointed to command the cruiser "Novara." After Italy joined the Allies Horthy distinguished himself in the naval raids on Porto Corsini and San Giovanni di Medua, and particularly at Otranto, where on May 14 1917, with the cruisers "Novara," "Saida" and "Helgoland," he broke through the ship cordon blockading the Straits of Otranto. Horthy, although severely wounded, remained on deck and continued the fight until he succeeded in returning safely with his ships to his home port, despite the enemy's heavy fire. He was awarded the Military cross of Maria Theresa. Near the end of the War Horthy was appointed commander-in-chief of the Austro-Hungarian fleet.

After the collapse of the Monarchy and when revolution broke out in Hungary Admiral Horthy returned to the home of his ancestors and began to organise the counter-revolutionary forces in southeastern Hungary. Thanks to his popularity as a war hero, Admiral Horthy added considerably to the influence of the informal counter-revolutionary Government of Count Julius Károlyi, which in Hungarian territory occupied by French troops endeavoured to form a nucleus for all partisans of law and order. When it became obvious that the fall of Bolshevism was imminent, the second "Szeged Government" appointed Horthy to be commander-in-chief of the national army, which, after the flight of the people's commissioners (Aug. 1919), entered Transdanubia and succeeded in restoring order in territories where law and discipline had been upset by the Red Terror of Bela Kun. When the Rumanians finally withdrew their troops from the centre of Hungary the new national army, with Horthy at its head, entered Budapest on Nov. 16 1919 amidst the cheers of the population.

The restoration of order was no light job, and it was done with no light hand by a sailor who regarded the spirit of discipline in his ship as more important than the praise of kings or the blame of politicians. Horthy has been frequently attacked for failing to restrain retaliatory outrages of those who suffered under the Red Terror, and who themselves created what has generally been termed the White Terror. It must be remembered, however, that all the normal forces for maintaining order had previously been dispersed, and that without such forces it was practically impossible to control what was a natural reaction, however regrettable. When in Feb. 1920 the national assembly of Hungary was elected, Admiral Horthy, still commander-in-chief of the army, was practically the only possible candidate for the regency. Consequently he was elected to this office on March 1 1920.

As regent or governor, as the office is variably termed, Admiral Horthy had the bitter duty of ratifying the Treaty of Trianon, which his second Government, that of Count Paul Teleki, carried through in Nov. 1920. The gravest responsibilities, however, which the regent was called upon to meet were the two attempts of the late King Charles to regain the throne of Hungary. The regent of Hungary was then in a desperate conflict between an allegiance sworn as admiral and privy councillor to his king and the oath taken as regent to the Hungarian national assembly. First, in April 1921, he refused to obey the summons to hand over the Government to King Charles when the latter came to Hungary unarmed. On that occasion the Hungarian Govt. succeeded by peaceful means in getting the king to leave the country. At his second venture, in Oct. 1921, King Charles came with troops against the capital. regent and Count Bethlen's Government had no alternativ to fight him, as the Allied Powers and the states surroun Hungary were definitely opposed to the restoration of a Habs monarchy. It was a poignant task for the regent to disarm hand over to the former enemy powers the anointed beare St. Stephen's crown.

As the disturbances inevitable after revolution, Bo vism and monarchical "putsches" died down, and the li the country became more normal, the personality and ac of the regent ceased to have such critical importance. R sentative government, exercised through the national assen resumed its ordinary sway, and Admiral Horthy performe duties with constitutional correctness, supporting the ef of Count Bethlen's Government towards the economic re struction of the country. He had to lead his country thr difficulties which few men in history have had to face, and small wonder that in doing it he had to take drastic meas and has made many enemies. It is doubtful, however, if gary could have found a regent more energetic in times of or equally constitutional in times of peace. Horthy ma described as a typical sailor, frank and simple and dire manner, with no suspicion of diplomacy, and devoted to s but in official life a strict observer of the ceremonies which pertain to the head of a state that is still a monarchy.

(W. Go

HOSPITALS (*see* 13.791) (1912–25).—At the beginning o period under review two special points should be noted in nection with the general development of hospitals:—

1. The development of operating and clinical methods led increasing specialisation in the departments of general medi and surgery in hospitals.

2. From the architectural point of view, simplicity and fort were being increasingly sought, and buildings and hos premises were being to an increasing extent adapted to necessities of sanitation and hygiene.

General Features.—Attempts to create large hospitals ou urban centres and in favourable climatic conditions have to a large extent successful. In the case of old hospitals, it was difficult to make rapid changes, the various services been installed in special buildings and annexes, divided one another, each dealing with a special subject, *e.g.*, surgery, cli work, ophthalmic work, otolaryngology, children's disea gynaecology, epidemics, etc. Whereas in Anglo-Saxon hosp the principle of placing hospitals under independent ma ment maintained by voluntary aid has been adhered continental countries there has been an increasing tend to centralise hospitals by placing them under municipal, or national authority. The former method tends to encou individual initiative and the desire to make each hospita perfect as possible. The latter allows of the most practica economical distribution of the various services betwee departments concerned.

Statistics.—Hospitals were more frequented in 1912 tha previous years. This fact must be attributed not to the incr in the tendency to disease, but to the addition of a large nu of buildings and wards which allowed of a larger numbe patients being received. The dissemination of the principle hygiene has familiarised the public with medical methods has caused a marked increase in the number of patients treatment. Various statistics show the movements of pa in hospitals during the years preceding the War. In 191 hospitals in London (general hospitals, children's cli gynaecological hospitals, anti-tubercular hospitals, etc.), 9,171 beds, dealt with 134,749 patients, and were attende 1,329,567 persons.

In 1912, the Paris Department of Public Relief (*l'admi tration générale de l'assistance publique*) admitted to its ge hospitals (Andral, Beaujon, Boucicaut, Broussais, Cha Cochin, Hôtel-Dieu, Laennec, Lariboisière, Necker, Pitié Antoine, St. Louis and Tenon) 147,828 patients, and 46 patients to the special hospitals (St. Louis, Maternité, Br

Germany, in 1912, had 9,054 hospitals with 535,579
This figure includes general hospitals, military and naval
als, lunatic asylums, sanatoria, maternity homes, special
, children's hospitals, homes for the blind, etc. In 1912,
edical institutes of Vienna dealt in all with 82,939 patients.
e United States there was a noticeable increase in the
er of hospitals and clinics, and there was a considerable
pment of the specialisation of medical and surgical de-
ents.

r Conditions.—The World War of 1914 compelled hospitals
pt themselves rapidly to new requirements, *e.g.*, assistance
wounded, ambulance work, mobile hospitals in the army
medical staff, additional nurses, etc. Existing hospitals
ransformed to meet the new requirements. In addition, a
number of extra establishments were improvised.

itary and naval hospitals are directly dependent on the
ry medical service and are divided as follows:—

Permanent military hospitals, already existing in time of peace,
pecially adapted for the reception of sick and wounded sol-

Civil hospitals were placed, together with their staff, under the
ion of the military authorities;
Hospitals were installed in public or private buildings, such as
, schools, private houses, etc., to receive and deal with the
wounded from the front;
Hospitals in the zone of military operations were carried on in
nent premises or under canvas, even underground, nursing
and relief posts dealing with first aid to the wounded before
vacuation to the rear.
As described in the article MEDICAL SERVICE (ARMY), ambu-
of every type were employed. Aeroplanes, trains, barges and
specially converted and equipped, were used for the transport
and wounded to base and home hospitals.
Special hospitals for orthopaedic, for tuberculous, neurasthenic,
sed and gassed cases were organised. Electro-therapeutical,
-therapeutic, helio-therapeutic massage and special sections
also developed.
Convalescent homes were set up and many private mansions
used for this purpose.
Temporary hospitals were erected to receive influenza patients,
alaria camps were organised.

utral Countries.—In non-belligerent countries there was no
considerable change in the organisation of hospitals
een 1914–9. By the force of circumstances, the con-
tion of new buildings was slowed up, technical methods
ined more or less stationary, and the nursing staff tended to
ish, in view of the large number of volunteers serving in
elligerent countries. In 1917–8, statistics of the move-
of disease and mortality remained more or less equal
ose of 1914. Anti-epidemic hospitals were organised in
numbers in Poland, Russia, Hungary, Rumania and the
c countries.

arantine Stations.—Quarantine stations, which before the
were limited to maritime ports, were, after the War, set up
e borders of Poland, Czechoslovakia, Rumania, Hungary
the Baltic States, for the supervision of travellers arriving
countries contaminated by exanthematic typhus and re-
ng fever. Three model stations, set up by the International
Cross Committee at Narwa in Estonia, Riga in Latvia,
Iniö in Finland, dealt with the reception, supervision and
fection of thousands of prisoners arriving from Russia on
onvoys of repatriated prisoners between 1919–22.

ecial Hospitals.—The Italian Red Cross has been most
e in districts affected by malaria, and with this end in
has organised the anti-malaria sanatorium of Massalubrense,
ther with a number of motor ambulances. In Georgia, the
ical institute of Tiflis is engaged in centralising the work
e various clinics and hospital stations. In 1913 12,500
ria patients were treated in the hospitals of Tiflis. In
ntal countries may be mentioned the leper hospitals (the
es and Siam), hospitals for the treatment of snake-bites
nese Red Cross at Bangkok), and the anti-epidemic and
mer hospitals of the Chinese Red Cross at Shanghai.
itals have been supplemented by dispensaries, preventive
es, consulting offices, convalescent homes and mountain
toria and seaside hospitals. Venereal disease and derma-
tological hospitals have considerably developed. Cancer hospitals have been improved and perfected, especially as regards radio-therapeutic services, anatomo-pathological laboratories and radio-therapeutical, photo-therapeutical and radiological work.

Developments.—In 1924, the number of hospitals in London was 118 (as against 106 in 1913), the number of beds 13,460 (as against 11,840 in 1913), the number of patients treated 177,300 (as against 145,600 in 1913) and the number of consultations 6,677,000 (as against 5,020,000 in 1913). Among the principal hospitals included in these general figures, St. Thomas's Hospital alone received 10,139 in-patients and gave 488,600 consultations; St. Bartholomew's Hospital received 8,648 in-patients and had 344,226 out-patients, the London Hospital 17,331 in-patients and 553,965 out-patients, Guy's Hospital 9,495 in-patients and 487,452 out-patients. In Paris, the number of sick persons received was 238,912 in 1923, of whom 153,794 were in the general hospitals, 43,403 in the special hospitals, 29,329 in the children's hospitals, 2,071 in the mental hospitals and 10,315 in various homes and asylums.

C. de Gronkel (1925). (E. M.*)

United States.—During the period from 1912, and more particularly from 1914 to 1925, the development of hospitals in the United States has been unprecedented. This development may be considered under the heads of (*a*) the present trend of hospitals as a social factor, (*b*) the present day construction, (*c*) specific examples and (*d*) statistics of 1925 and the increase during the period in question.

Hospitals as a Social Factor.—While there is a continued development and refinement of the care of the sick in the hospital to-day, the conception of the function of this institution has materially broadened, with a rapidly increasing tendency to regard it as a community health centre from which to radiate all health activities, particular emphasis being placed upon the development of out-patient departments (this as a means of teaching and practising preventive medicine and thereby obviating the necessity of the hospital bed), district nursing and social service. In the larger cities medical centres are being developed, in which case the foregoing community functions are associated with the instruction of student bodies in various branches, including medicine, nursing, public-health work, social service, and, in many instances, dentistry.

The tendency to develop isolated speciality hospitals is being replaced by provisions for the specialities as departments of the general hospital or by the affiliation of already existing speciality hospitals with existing general hospitals. The different types of schools teaching health work, with the various hospitals, form these medical centre groups, in which are included convalescent homes as an integral or co-ordinated part.

Present-Day Construction.—While in the earlier period hospital development in the United States was largely patterned after the developments in Europe, the present trend of large institutions is toward the "skyscraper hospital"—as St. Luke's Hospital Annex, in Chicago, with 19 stories; the Jefferson Hospital, in Philadelphia, with 17 stories; and the new Presbyterian Hospital of the Medical Centre of New York City, now under construction, with 22 stories. This tendency is extending even into the country districts where the value of land is not a factor—the University Hospital at Ann Arbor, Mich., with its nine stories, being an example.

Economy and effectiveness of administration is claimed by the promoters of the multi-story hospital movement. The newest developments lay emphasis upon small wards with a maximum of 10 or 12 beds, numerous single rooms for patients of all types, and elaborate facilities for private patients. In this type of construction it is quite common to find the kitchen, laundry and all essential services provided for in a single building along with the housing for the patients. This type of construction and administration, which is distinctly American, is not at this writing being followed in the United States to the entire exclusion of the methods commonly pursued in Europe.

Specific Examples.—A typical example of the hospital movement in the large American cities is to be found in the Medical Centre in the City of New York, in which the Columbia University College of Physicians and Surgeons, Presbyterian Hospital, Sloane Hospital for Women, Vanderbilt Clinic, The Babies' Hospital, Neurological Institute, State Psychiatric Institute and Hospital, Presbyterian School of Nursing and certain other schools and hospitals are reconstructing their institutions on a single plot of ground, having jointly undertaken all the branches of medical teaching, research and care of the sick, their simultaneous constructional programmes involving $20,000,000.

Increase in Recent Years.—At the close of the year 1925 a complete census of all the hospital facilities in the United States, however owned and controlled and for whatever type of patient, showed that there were 8,695 hospitals—a figure somewhat in excess of 50% of the number of institutions of this character in the world. These hospitals provided a total of 836,576 beds, of which 34,511 were bassinets. This compares with 5,037 hospitals, with 532,481 beds, in 1914. Of the total number specified, 341,480 beds are devoted to the care of mental and nervous diseases.

While the development of the large institutions has made unusual progress, yet the growth of the small institutions in the smaller communities seems to have a special significance and to be indicative of the popularisation of the hospital in the public mind. While in 1920 44% of the 3,027 counties in the United States had community hospitals, the record of 1925 shows an increase to 56%; 52% of all the hospitals in the United States being of 40 beds or less. The close of the period finds recorded 1,117 new buildings planned, with $309,000,000 involved in a year's construction; the total value of hospital properties being variously estimated between $4,000,000,000 and $5,000,000,000.

In the year 1925 the 56 privately owned hospitals of all types in New York City receiving partial support from the United Hospital Fund reported 12,022 hospital beds, 230,988 cases, and 3,456,111 days of hospital care—this being independent of the state and municipal hospitals in New York City. All types of hospitals in New York City, excepting those for the insane, provided 32,167 beds, treated 510,859 patients and gave 8,813,721 days of hospital care; treated 1,028,347 cases in out-patient departments and had a total of 3,595,261 out-patient department visits.

HOUGHTON, ALANSON BIGELOW (1863–), American diplomat, was born at Cambridge, Mass., Oct. 10 1863. He was educated at Harvard (B.A. 1886), subsequently studying at Göttingen, Berlin and Paris. He associated himself with the Corning Glass Works N. Y., in 1889, becoming successively vice-president and president, and, in 1918, chairman of the board of directors. He was elected a member of Congress in 1919 and re-elected in 1921, resigning in 1922 on his appointment by President Harding as U.S. ambassador to Germany, a position which he held until 1925, when he was appointed ambassador to Great Britain in succession to F. B. Kellogg.

HOUGHTON, WILLIAM STANLEY (1881–1913), British playwright, was born at Manchester Feb. 1881, and educated at Manchester grammar school. He became a cotton broker, but employed his leisure in dramatic criticism for *The Manchester Guardian* and in the writing of plays. *The Dear Departed* (
was produced by Miss Horniman at the Gaiety Theatre, Ma
ter, in 1908 and afterwards in London. With *Hindle Wakes* (
he leapt into fame. It had a long run in London and later i
same year *The Younger Generation* (written and played in
chester in 1910, 2nd ed. 1913) was successfully produced a
Haymarket Theatre, London, with *Trust the People* (191
following year at the Garrick and *The Perfect Cure* (1912) a
Apollo. His early death in Manchester, Dec. 10 1913, cut s
career of much promise.

HOURS OF LABOUR (*see* LABOUR LEGISLATION, 16.7).—
position in regard to hours of labour reached in the years i
diately following the Armistice of 1918 was further consoli
during the succeeding years and in some directions a move
was made towards a further reduction of the daily and w
working hours, in practice as well as by legislation. The Eur
economic crisis, however, particularly that occasioned by the
the German mark, the abnormal unemployment in Great Br
in Switzerland and later in Germany reacted on the nationa
international position in regard to working hours and tend
check the movement towards general reduction. The weig
the reparations burden upon Germany weakened the cam
of the trade unions there towards shorter hours, and Germa
rivals felt the influence of the longer hours ("Mehrarb
which were instituted, with the consent of the German
unions, in certain branches of industry in 1924.

Many workers during this period showed themselves rea
undertake overtime work whenever possible, or even to
a "second eight"—in another factory or workshop at the
clusion of their normal day's labour. This latter case was
on grounds of social policy, a statutory offence in some coun
and was frequently used as an argument in favour of the
working day. These phenomena contradict the experien
the pre-War period; they are explained in certain countries
depreciating currency by the failure of wages to keep pace
rises in the cost of living, in others by the prevalence of u
ployment, which has given the employer a powerful wea
against the worker whose chance of obtaining new employm
once thrown out of work, is very slight. In either case the fo
the temptation upon the worker to earn as much as possi
obvious, and the trade unions have sometimes (notably in F
and Italy) had to abandon their traditional opposition tow
overtime, or even moderate their insistence upon increased
of pay for overtime work. In Germany the trade unions
for a time their demand for overtime pay in regard to the "M
arbeit" hours, whilst retaining it for any further hours.
Great Britain, the overtime rates were almost universally
tained owing to the strength of organised labour.

I. THE GENERAL INDUSTRIAL STANDARD

Standard Day and Week.—But these weakenings of the ge
movement were everywhere recognised as exceptional and as
to temporary factors. Public opinion in general as reflect
the various legislatures supported the trade unions in their
sistance to any demand for extension of hours, and the "st
ard" working day or working week has successfully maint
itself. In Great Britain collective agreements showed no tende
towards an extension of hours; successive parliamentary atta
on the Belgian 8-hour Act of 1919 were easily repulsed; in
Netherlands, though the 45-hour week established by law
came 48 hours for certain branches of industry and comm
(and thus was brought to the international normal) excep
to the latter were permitted only temporarily and to meet spe
emergencies. The ceding of the "Mehrarbeit" in Germa
whereby the workers in certain industries agreed to work a
tional hours, usually four to six per week, without demanding
increased rate of pay for these hours, was their contribution
wards improving the situation brought about by the neces
of reparations payments. It led directly to a correspond
extension of hours in the neighbouring and competing h
iron industry of Polish Silesia (declared by the Governmen
be temporary and dependent on the German situation),

difficulties, without however actually bringing about ension of hours, in Czechoslovakia. The "Mehrarbeit" ıly temporary: a statement of the German Minister of r in March 1926 showed that less than 500,000 industrial s out of a total of 12,000,000 workers covered by collective ıents worked normally more than the 48-hour week. The n in Poland was amended *pari passu* with the improven Germany. From Aug. 1925 the extensions permitted, allowed in certain branches of industry a 10 instead of an day, were gradually withdrawn, and the situation at the 1925 was nearly normal.

"8 and 48" rule maintained itself as a "standard," and e quarters was even held to have the demerit of many standince movement towards it may be from below 48 as well as bove it. The Netherlands 45-hour week became in effect ɔur week; the Polish 46 was in the same danger.

orking week of less than 48 hours is not uncommon. Rigid ation of the 8-hour day in combination with the "English end" leads to a 44-hour week, which became the legal inıl limit in New South Wales and Queensland from Jan. West Australia, however, rejected a bill to this effect. In Britain working hours (except in regard to women and en, mine-workers and employees in certain "sweated") are not regulated by law, but by collective agreements. nany such agreements provide for a week shorter than 48 In the metal trades, wood-working and furniture, and the ering and shipbuilding it is 47; in building generally 44; tiles, whilst most agreements provide for 48, the frequent ce is to work 45 or 46. A proposal by the engineering ems in July 1925 to extend the working week from 47 to 50 w of foreign competition met with no success, and a similar sal made for the same reason to extend the miners' working om seven to eight hours was not supported by the Comn which enquired into the conditions of the coal industry 6. Attacks in 1924 and 1925 on the Polish 46-hour week rly failed, though their basis was the opportuneness of a . to the "normal" 48.

ould seem fairly clear that the rule is to be maintained, and erely as a standard, but as a maximum. It seems to be a definitely gained, from which further advances in social ess may be made as conditions permit.

plication of the "8 and 48" rule.—In fact the "8 and 48" s now very generally established for industry throughout ɔe, including Soviet Russia, either by law or by collective nent. The details of its application vary. It is not univerapplied to all factories and workshops; in Sweden and Switd it is not applied to very small establishments. Nor is it y rigidly enforced: factory inspection, which is very effiin Germany, the Netherlands, Belgium, Great Britain, ıoslovakia and the Scandinavian countries, is much less nt in France and Italy and virtually non-existent in certain countries. Its application depends, too, upon the vigilance onsciousness of the trade unions. Where they are strong, r collective agreement is valid in practice; where weak, both ɔyers and workers can often offend against either with comive impunity. Nevertheless, such dependable statistics as vailable show a high degree of uniformity in the average actually worked in corresponding industries in the various pean countries; and, at least in the great industrial states, nents concerning unfair competition based on alleged difces in hours—except in rare and unusual cases—should be carefully examined before being accepted.

e rule holds too in the British Dominions generally, though with differences of application, and has recently made progress in the United States, where however it tends to the form less of a fixed maximum than of a "basic" rule ıe determination of wages. A decision (1925) of the Railroad d, for example, provides that all hours worked over eight e day shall be paid for at increased rates; thus the 8-hour is accepted as the normal whilst the working of additional is not prohibited. This is in agreement with the Internal Convention of Washington, which makes no attempt to restrict overtime internationally further than to insist on an overtime rate of 25% above the normal. In South America, wherever legislation on the subject exists, the "8 and 48" rule prevails.

In the important industrial states of Asia the working day and week are normally longer than in the countries hitherto mentioned. Progress in the reduction of hours except in India has been slow. The reluctance of Japan to reduce her working hours is probably the main factor in the situation. A second is the confused state of China, where factories working 12 and 14 hours a day exist side by side with others which have introduced and 8- or 9-hour day. An attempt to reduce hours by general agreement in certain Chinese cities, notably Shanghai, met with partial success only. Persia has not many industries susceptible of regulation in this matter; in her carpet industry, which employs numbers of children, sometimes of tender years, hours are restricted to eight daily. In Palestine, although legislation was lacking, the immigrant Jewish population, which brought with it the industrial concepts of Europe, secured for itself by agreement with the employers the almost complete application of the "8 and 48" rule, which it endeavoured to extend to the Arab workers. In 1925 Turkey adopted legislation providing for a 60-hour week—the first limit imposed by statute—to include the time necessary for prayer, and for the cleaning of work-places and machines. Miners work a 6-hour day.

Hours of Labour in Asia and Africa.—Recently increased attention has been paid to the question of the working hours of native races not yet accustomed to the regularity demanded by modern conditions and now forced upon them in the rapid development of many hitherto untouched areas. Plantations, mines, road and railway construction and even factories are making enormous demands upon the native populations of, for example, Central Africa, and the transition to modern industrial conditions appears to be very difficult. Many experts in colonial affairs hold that an 8-hour day for many of these natives is much too arduous; yet much longer hours are often exacted. The mortality rates among native workers are disquieting; in recent years rates of 8 and 10% per annum have been recorded in Africa, and these in areas where supervision is better than the average. Some attempts have been made to meet the situation; hours are limited to eight in certain African mining areas; the immigrant Chinese workers in Samoa (under mandate to New Zealand) have an 8-hour day, and it is becoming regular both in Asia and in Africa that, where workers are engaged under indenture or contract, the number of daily working hours (usually eight) shall be inscribed in the indenture. In the more important islands of the Dutch East Indies hours are regulated by law, or are prescribed in indenture. It is clear, however, that the problem of the utilisation of the labour of these peoples without injury to their physique and their numbers is far from being solved, and that the question of their working hours has not yet been sufficiently examined.

Exceptions to the "8 and 48" rule.—The "8 and 48" rule clearly cannot be and is not applied to all industrial occupations indifferently, and some have been excepted from its application both in national and international legislation. Among the difficulties of application is the redoubtable scourge of the 12-hour day in certain continuous processes, and in some seasonal industries. The two-shift system in continuous processes is replaced, in the International Convention on hours, by that of three shifts: the 12-hour day and 84-hour week thus becoming the 8-hour day and 56-hour week. This change, which involves a large increase of staff, has been strongly resisted, and has not yet been inscribed in all national legislations; but the old system is disappearing, even in the United States, where the two-shift system and the 12-hour day were specially prevalent. In some seasonal occupations, notably in the sugar beet industry in Europe, the great difficulty of bringing more temporary workers and accommodating them near their work for the 10 or 12 weeks of the "season" has prevented the reform in some areas; in others where conditions are more favourable, it has been carried out in spite of the handicap in competition involved; the social advantages have triumphed over the economic disadvantage.

The distribution of work over the days of the week implied in the "8 and 48" rule may not always correspond, not only to the economic needs of a particular case, but to general changes of opinion on these matters. The English week-end (short Saturday), for example, has become much more general over the continent of Europe; it is the rule in the British Dominions and in the United States and spreading elsewhere. It is not consonant with a strict application of the 8-hour day and the 48-hour week, and has led sometimes to the institution of a 44-hour week, sometimes to the working of more than eight hours on some days to compensate for the shortened Saturday.

A relatively new development—the five-day working week—shows signs of becoming popular. In certain industries it has long been the practice, in Great Britain, France and other countries, to complete the working week in five days, since the overhead expenses made it uneconomic to work a short Saturday of four or five hours. In Great Britain, especially since the War, with the consent of employers and workers, the practice extended, notably in boot and shoe factories and chocolate works where it is almost the normal, and it appears to be favourably received even where the economic argument is not perhaps so powerful as in the industries (*e.g.*, dyeing) to which it was first applied. The social attractions of the five-day week begin to outweigh the disadvantages involved of a 9- or 10-hour working day.

II. IN COMMERCE, AT SEA AND IN AGRICULTURE

Hours of Labour in Commerce.—In commerce, legislation on hours of labour generally belongs to the post-War period. The increasing development of the large departmental store has changed fundamentally the position in the shop-keeping world and has forced the regulation of working hours, either by legislation or by collective agreement.

In Great Britain both methods have been used, but the Shops Act of 1912 affects only the labour of young persons under 18 and provides for a maximum working week of 72 hours (including rest periods). Collective agreements and general practice have largely superseded the provisions of the Act. Few employees of large urban establishments now work 72 hours in the week, some only 43. The agitation of the organisations of shop-assistants for reduction has been generally successful. The obstacles to progress are the numerous small establishments which are frequently managed by their owners and have few or no paid workers in the ordinary sense; it is considered unjust to compel establishments which have employees to close whilst leaving open the small shops of the owner-workers. There is also the difficulty of changing the shopping habits of the general population.

Certain British regulations on closing hours adopted during the War period have not given general satisfaction. Nevertheless, many European countries have introduced legislation: Austria (1919), Czechoslovakia (1918), Finland (1917), France (1919), Germany (1923), Italy (1923), Poland (1919), Portugal (1919) and Russia (1922) have each adopted Acts which fix the normal working week in commercial establishments at 48 hours. In the Netherlands, the law of 1922 imposes 10 hours per day and 55 per week as maxima. In the other cases the 48-hour week seems to be rather the principle than the practice. The legislation itself provides for numerous exceptions and in a very much more elastic manner than is general in industry.

In Germany the hours may be lengthened by collective agreement between workers and employers, or by the judgment of an arbitration court, and the 48-hour week in commercial establishments is probably rather the exception than the rule. In Czechoslovakia, the law is seldom strictly applied. The French Act of 1919 permitted the application by decree of the 8-hour day and 48-hour week not only to industry but also to workers in shops and offices. A number of decrees have been issued, affecting for example employees in banks and public offices, and shop-assistants. Most of these decrees are regional in their application: it has been found easier to regulate hours in the larger towns. The decrees affecting industry (now covering all but very minor branches) cover the commercial workers attached to the industry (clerks and employees in the offices) also. In Italy a similar system of regulation is in effect in the larger towns.

A vast amount of local legislation, by-laws, etc., govern this matter, shop-keepers themselves very often fixing closing hours through their associations. Very little of this form of regulation however is definitely based on the notion of restricting working hours for employees; other factors enter into account.

Hours of Labour at Sea.—The seafarers' hours are still more difficult to regulate and relatively little national legislation on the question exists. The different categories of workers employed on a modern vessel, and the difference in the effort demanded of them is one cause of difficulty; another is found in the risk attached to the sea-service and the necessity of abandoning all regulation in time of stress. Yet a third arises, curiously enough, in the seaman's problem of what to do with himself on board ship when he is neither at work nor asleep. This latter is gradually being overcome by the more factory conditions now insisted upon by many states in reg living accommodation on board.

The vast majority of seamen, including the British, have ob regulation of hours by means of collective agreements, but in cases the legislatures have intervened. The most interestin probably the most successful interventions, are the Acts of F (1924), Norway (1919) and Sweden (1919). These divide th sonnel of a vessel according to the nature of its work: the engin staff is required to do not more than 16 hours work in two conse days, whilst the ordinary seaman works not more than 24 ho the same period. Other arrangements are made for small vess cases where the crew is not divided into watches, for coastal t and for work whilst in port. These Acts seem to have been satisfactory in application, though the seamen concerned dem reduction of the hours prescribed. A French decree of 1925 e ing the application of the 1919 general Act to the sea service pr alternative methods, either an 8-hour day may be worked, or hour week, irregularly divided as regards the daily limit averaging of hours over a month, the 8-hour average bein served. These hours are subject to exceptions to meet sea gencies. Greece in 1923 extended her general labour legislati decree to cover sea workers, but it does not appear that her legislation, which is somewhat special and not applied as yet land industries, has been adopted at sea. In Portugal w hours are regulated by a decree of 1923; whilst in port the 4 week is maintained, at sea the hours for the deck staff a stewards and pursers are 84, and for the engine-room 56. A S decree of 1919 lays down as maxima a 10-hour day for office for ordinary seamen, and 8 for the engine-room crew. In Yugo a decree of 1924 provides a 10-hour day and 60-hour week. Ur has applied the 48-hour week and Argentina has under conside the question of the regulation of hours at sea by legislation. mark is revising her maritime legislation upon the lines o Finnish, Norwegian and Swedish Acts.

The French decree above mentioned makes an important ne parture in defining "hours of *effective* work," An Act of 19 which this and earlier decrees were based had stipulated the day, but in practice and by a decree of 192 it had been cons that 12 hours of presence were held to constitute eight ho *effective* work. In 1925 the Council of State found this to be al and defined "hours of effective work" as "the time during the crew are, in consequence of an order given, at the disposit the captain and away from their ordinary living quarters." Thi important and far-reaching decision will have its effects on national legislation and agreements, including probably the jected legislation under consideration in Germany and the N lands. In both these cases the proposed reforms are stated based upon the principle of the 8-hour day.

In Great Britain the matter is dealt with solely by coll agreements, which are exceedingly complicated and not unive applicable. They are not so much intended to limit the ho labour directly as to secure that overtime rates are paid after a "normal" has been reached, and thus to penalise employers exact the longer day. Emergency cases (of which the master vessel is sole judge, and which may be cases of salvage, fog stranding or other circumstances affecting the safety of the are not usually affected by these overtime pay arrangements general, the agreements provide for overtime rates when the w day in port exceeds eight hours, with special arrangement Saturday (five or six hours) and Sunday (ordinary necessary r work up to four hours), and for days of arrival and sailing. A the ordinary system of watches results in a longer day being w except for the categories known as day-workers (*i.e.*, those normally work only during the day) who have similar hours to detailed above.

This may be taken as fairly typical of the terms arrange collective agreement, not only in Great Britain but elsewh countries where legislation has not been adopted. The Aust and New Zealand seamen however have secured better terms. agreement they have a strict 8-hour system which is probabl most favourable to the workers yet obtained anywhere; the qu of its consecration in legislation is stated to be under conside

Hours in Agriculture.—The attempt to apply the regulati hours of labour to agriculture has aroused keen controversy. lation on the subject is still experimental, and a perfect syste yet to be devised. Little or no legislative regulations existed b 1918, though Ecuador in 1916 passed an Act that "No laboure engaged in agriculture shall be compelled to labour more than hours daily, six days per week." Information as to the succe application or otherwise of this law is lacking. Where so muc pends upon the seasons and the weather, and where the ca animals and crops makes demands that have often little refe to a time-table, the regulation of hours is complicated and dif Nevertheless it has been more or less scientifically attempted b in several countries, and has come into practice by agreeme others.

The German regulations, issued under the provisional Ag tural Labour Act of 1919, make a serious attempt to deal wit question of seasonal variation of work, prescribing daily maxi

nd 11 hours during three four-monthly periods into which the
as divided for this purpose. Time spent in travelling to and
he farm is calculated as working time—another point which
used much difficulty in agriculture and in other occupations.
zechoslovakia, the Act of 1918, which introduced the 8-hour
ry generally, seems to have become in practice an Act for
ing wages, so far as agriculture is concerned. There does not
to be in fact any limit upon the hours worked, but overtime
must be paid for hours worked beyond an average of eight
ay. Portugal (1922) prescribed a maximum working day.
a (1921) prescribed a maximum yearly average of nine hours
Austria an average of 10 in Lower Austria; in Upper Austria,
onsecutive hours of rest and two hours for meals are provided
e possible working hours being thus limited. An Estonian
1921 created district joint commissions which were empowered
e upon hours, with a maximum of nine daily on a yearly aver-
is stated however that these commissions do not work well,
at the hours situation is confused. The Spanish decree of
does not appear to be rigidly applied, and little information
ilable as to the working of a Costa Rican decree of 1920. In
ases the 8-hour day was the basis of the systems laid down.
taly collective agreements from 1900 onward specified gener-
from sunrise to sunset" as the limit of working hours, with
eriods of from three to four hours during the summer day and
r ones in spring, autumn and winter. In April 1919 an agree-
was made in regard to day-workers (mostly the seasonal
rs employed in rice cultivation) providing an 8-hour day, with
rates for overtime. The collective agreements made between
and 1923 secured progressively favourable conditions for
ltural workers; the advent of Fascism however changed the
n fundamentally and the rural custom of collective bargaining
virtually over. Alongside the system of agreements in Italy a
tive code governs hours in agriculture. The migratory workers
rice areas, who are mostly women, were the subject of legisla-
s early as 1866, and their hours are now determined (apart
the results of collective agreements) by regulations of 1908
under the Public Health Code of 1907, which prescribe a 10-
day for workers resident on the rice estates and a 9-hour day
hers. Other agricultural workers (day-workers and those with
d annual salary) are further covered by a Royal decree of
issued in pursuance of a Legislative decree of the same year,
lays down the 8-hour principle but permits a 10-hour day dur-
period not exceeding three months in the year.

England and Wales legislation does not directly affect hours,
he Agricultural Wages (Regulation) Act of Aug. 7 1924 regu-
them indirectly and indeed has given the best results of legis-
in any country. The District Committees set up under the
ave the power of fixing weekly wage rates, and in so doing they
based the rates upon a certain number of hours of work per
in general between 48 and 52, but in some cases extending to
onger hours than these are indeed worked, but must be paid
overtime, and are thus avoided or reduced to a minimum wher-
possible with suitable arrangement of hours. The agricultural
er here further enjoys the "guaranteed week"; he is guaranteed
ull minimum week's pay even though weather or other condi-
make it impossible to work the total number of hours. This
ntee of pay in occupations where irregularity of hours is a
re, may prove a solution of much difficulty. It exists on the
sh railways, and in a modified form at the docks. Excepted
the guarantee in agriculture are, in general, female workers,
e wages are usually fixed on a casual hourly basis.

llective agreements are not ruled out by the British legisla-
quoted, and in fact play a large part, within the framework
ided by the work of the District Joint Committees, in the
g of hours.

III. INTERNATIONAL ACTION

he Washington Convention.—The standard "8 and 48" rule was
ecrated in the Convention on Hours in industry adopted by
first session of the International Labour Conference, held at
hington in 1919. Its adoption was based upon general prac-
at the end of the War and upon the resolutions of many in-
ational congresses and conferences of previous years, as well
pon the opinions of governments expressed in the documents
ared for this session. The Convention provides, in brief, for
-hour day and a 48-hour week in industrial establishments
l sizes except in workshops where only members of the same
ly are employed. It makes special provision (eight hours daily
56 weekly) for continuous processes; it permits more than eight
s daily where a short Saturday is worked; it allows excep-
s of a permanent nature for workers whose duty it is to pre-
beforehand for the general running of the establishment,
r example enginemen in a factory, or who must be employed
time after the general work of the establishment has ceased,
for intermittent work; it provides also for exceptions of a temporary nature to meet unusual pressure of work. By a special and very elastic Article it permits the 48-hour week to be exceeded, provided the average of 48 is maintained over a period of three weeks or more, where the ordinary rule is not capable of application. It leaves overtime to be regulated by the states themselves, stipulating only that employers and workers shall be consulted, and that an overtime rate of not less than one and a quarter times the normal rate shall be paid.

Since 1919 the question of the ratification of this Convention by the State Members of the International Labour Organisation has been the predominant issue in international labour affairs. By March 1926 Bulgaria, Chili, Czechoslovakia, Greece, India and Rumania had ratified it unconditionally and Austria, Italy and Latvia conditionally upon the ratification of certain other countries. In Brazil, Denmark, Estonia, France, Germany, Lithuania, the Netherlands, Poland, Spain and Uruguay the governments concerned had recommended its ratification to their Parliaments, but the latter had not yet signified their approval. The great European industrial states were still holding back, as was Japan. In India, which had ratified the Convention and materially reduced her working hours in consequence, employers and workers alike continued to protest that, with Japan refusing to reduce her working hours, amelioration in India and China was impossible. The great European states were reluctant to bind themselves unless assured that their industrial competitors would be equally bound. At first some governments held that the provisions of the Convention were too rigid; then, that they were too elastic, and that their ratification and application would not necessarily, owing to different interpretations of their terms, lead to uniformity of action. Hence the conditional nature of the ratifications of Austria, Italy and Latvia and hence also similar conditions inscribed in the bills for ratification submitted to the parliaments of certain other countries.

In Great Britain, difficulties of another nature hindered the progress of a bill for regulating hours and making possible the ratification of the Convention which was introduced by the Government of Mr. MacDonald. It was held in some quarters that the existing agreements regulating the hours of work on railways could not be brought into accord with the Convention; the railway employees were reluctant to change these agreements, and the Government therefore hesitated to take action which might, it was thought, precipitate a crisis. Differences of interpretation were possible also on various other points and consequently, in order if possible to arrive at agreement upon them before ratification, a meeting of the Ministers of Labour of Great Britain, Belgium, France and Germany was held at Berne in 1925. The meeting was partially successful, but the British Govt. decided to convoke the same ministers, with a representative of the Italian Govt. in addition, to a conference in London in March 1926.

The London Agreement, 1926.—At this meeting, which was prepared for by the circulation to the governments concerned of a memorandum on the points at issue, to which all replied, complete agreement was reached on all the issues raised, with one exception mentioned below. This agreement, signed by all the Ministers present, is likely, to have far-reaching effects on the fate of the Washington Convention and on the question of industrial working hours in general. It covers the following points:—

> Working hours are defined as those during which the workers are at the disposal of the employer; deductions for rest pauses and breaks, except scheduled breaks for meals, are therefore not possible, and this decision disposes of much controversy on the question of "effective" working time and the system of grading occupations in accordance with a scale. This is made even clearer by the agreement upon a definition of "intermittent work," the effect of which is to confine the application of this term to such occupations as those of door-keepers and watchmen which "are not concerned with production properly so-called and which, by their nature, are interrupted by long periods of inaction during which these workers have to display neither physical activity nor sustained attention, and remain at their post only to reply to possible calls."
>
> The Conference further agreed upon matters concerning the five-day week (see above) the regulation of overtime, and overtime pay (with the agreed minimum of 25%), the working of railways (thus removing an important British difficulty), and the recuperation

of time lost by holidays. On all these questions opinion was unanimous, but on one last point—the possibility of the suspension of the application of the Convention "in the event of war or other emergency endangering the national safety"—the British Minister reserved approval pending consultation with his Government.

The conclusion of this agreement removed many important difficulties in the way of ratification of the Convention by the European industrial powers. The ministers undertook to report to their Governments, which could then proceed with their consideration of the question of ratification. In the cases of Great Britain and Germany, at least among these Powers, it would be necessary to secure the adoption by the parliaments of new legislation, and in France and Italy new administrative measures would be required. If these difficulties could be overcome, and the ratifications of the five countries registered (simultaneously or otherwise) the international position of the "8 and 48" rule would be secured.

Protection.—The Berne and London Conferences of Ministers of Labour were reflections of the preoccupations of the governments and of the employers more directly than of the workers, who meanwhile formulated and discussed other policies in regard to the Washington Convention. In British trade union circles, for example, the revival by the Safeguarding of Industries Act of the policy of protection gave rise to the proposition that what workers should be more precisely protected against is that form of unfair competition which consists in exploiting their fellow workers abroad, and that the only form of "protection" acceptable to the workers as a whole would be one which would differentiate against goods produced by such methods and, in particular, by the exaction of excessive working hours. The adoption of such a policy, it is claimed, would give a powerful weapon to the more advanced states and enable them to insist on social progress in other countries whose backwardness retards the general advance in welfare. Similar ideas inspired the Austrian Social Democrats who carried in the Lower Chamber a resolution to increase import duties by one-third in the case of goods coming from countries where the conditions of employment, particularly in the matter of hours, were not satisfactory.

In the international field the same ideas appear to be gaining ground. In 1925 a joint committee of the International Socialist Congress and of the International Trade Union Congress decided to examine the possibility of a system of boycott applied to goods manufactured in countries where the Hours Convention is not observed. Later on in the same year a committee of the British Labour party published a report recommending such a boycott, which, it was stated, was not without precedent. Books which contravened the law on copyrights, and goods manufactured in foreign prisons cannot be imported into Great Britain; the great chocolate manufacturers have agreed not to purchase slave-grown cocoa. On the same principle, goods produced under conditions inimical to the worker should, it was argued, be refused admission. These proposals indicate a tendency which may develop as Labour or Socialist Govts. become more general and as the interdependence of states one upon another in the matter of social amelioration becomes more widely recognised. The Washington Convention affects industry only; hours in commerce, agriculture and employment at sea are not as yet regulated by any international convention.

Commercial, Maritime and Agricultural Hours.—The International Labour Conference has not yet considered the question of working hours in commercial undertakings. In 1920 a draft Convention instituting the 8-hour day, with suitable modifications, for seafarers was lost at the Conference of Genoa by a fraction of a vote. Since then the question has been the subject of constant negotiation between seamen and shipowners, and the organisations of the former, national and international, have decided (1926) to urge that the subject be placed again on the agenda of the Conference. The Conference at Geneva in 1921 held the moment not ripe for the regulation of hours in agriculture. Indeed no proposal to limit working hours in agriculture in the precise way which is possible in industry was ever put forward. Agricultural conditions do not lend themselves so readily as do those of industry to the fixation and limitation of hours, but it seems prol that international action in the matter cannot be long dela the hours exacted from agricultural labourers in many coun are unconscionable and are a powerful factor in bringing a the very active migration to the towns, which is a troubles social problem in almost all modern states.

Charter for Native Labour.—Equally pressing is the nee international action in regard to the hours of labour exa from subject populations in colonial areas. Here again the creasing force of competition makes it difficult for one cou to advance in this as in other social matters unless neighbou areas move forward also; yet it is probably true that the suff entailed by delay is more intense and the economic waste and is relatively greater in these areas than in the countries where population is capable of defending itself. As has been said ab local legislation has made a beginning and on the basis thus vided it seems possible that international action may be called upon to build. The discussions on the Draft Conven on Slavery adopted by the Assembly of the League of Nation 1925, though it did not enter into the details of the regula of native labour, showed clearly enough that there was a spread feeling that a "Labour Charter" for native peoples an urgent necessity. The resolution of the Assembly called the attention of the International Labour Organisatio this necessity will not, it is to be supposed, remain without eff and undoubtedly the hours question must be one of the first it is one of the most important, to be dealt with by the mem of the League of Nations.

REFERENCES.—The texts in English, French and German of of the Acts cited above, and in general of Acts relating to Hour Labour, are published by the International Labour Office in "Legislative Series." Monographs on the hours situation in a ber of important countries have been issued from the same sou For the general situation in regard to the Convention of Washing see the Directors' Reports to the successive sessions of the In national Labour Conference since 1919. The text of the conclus of the London Conference of March 1926 was published in *Times* of March 20. For hours of work in agriculture (Engl and Wales) see Report of Proceedings under the Agricultural W (Regulation) Act, 1924, issued by the Ministry of Agriculture Fisheries. (H. A. G.*

HOUSE, EDWARD MANDELL (1858–), American sta man and diplomat, was born at Houston, Tex., July 26 1858 seventh son of Thomas William House and Mary Eliza Shearn. His father, who had left England as a boy, came Texas when it formed part of Mexico, joined the revolu and helped to free it and bring it into the Union. The you House was educated at the Hopkins Grammar School and nell University, and returned to Texas in 1880, where he l for more than 30 years as planter. His chief interest, howe was public affairs. He took an influential part in the succe campaigns of Governors Hogg, Culberson, Sayers and Lanha and during the period 1894–1904 his political influence in Te was regarded as decisive.

He refused invariably to become a candidate for office hims but he acted as the intimate adviser of the several govern named. Although frequently urged to participate in natio politics he remained aloof from the disastrous Democra campaigns that followed the Bryan candidacy of 1896; but 1912 he played a major rôle in securing the nomination Woodrow Wilson, and at the time of the election Wilson had co to put full trust in him, offering him a choice of Cabinet positio Following his custom, House refused any office, but politica as well as personally he remained closer to the President th any member of the official family. It was upon his recommend tion that Wilson chose a number of his Cabinet; after t inauguration both President and Cabinet utilised his wi knowledge of men and his shrewd estimate of political effects help them in meeting legislative and administrative problem he exercised a great influence in the framing of the Fede Reserve Act and also played an important part in th organisation of the original Federal Reserve Board. Wils spoke of him as his "independent self."

use's chief interest lay in foreign affairs, and through close ct with American ambassadors abroad and his intimacy European statesmen, as well as the confidence of the lent, he was able to influence the course of American n policy. In 1913 he helped to tide over the crisis in ons with Great Britain over the Panama tolls exemption Wilson secured the repeal of the exemption. In 1914 he took formal negotiations with the diplomatic representa- of Argentina, Brazil and Chile, which led to the drafting pan-American pact designed to guarantee peace in the ern Hemisphere. The proposed pact was never translated a formal treaty, but it was of historical significance as ing an initial step in the development of Wilson's policy of ing a League of Nations. In the spring of 1914 House, ap- nsive lest war should break out in Europe, sailed for any to offer the assistance of the United States in reaching arrangement between England and Germany which might war. He talked with high officials of the civil Government, rmy and navy, and had a conference with the Kaiser, in he received some encouragement. William II. later said:— e visit of Colonel House to Berlin and London in the spring 14 almost prevented the World War." At London he found dward Grey ready to entertain any feasible plan to preserve . This, House wrote to the Kaiser on July 7 1914. The ler of the Archduke Francis Ferdinand, however, pre- ated war before the plan could be developed.

turning to the United States, House maintained close in- cy with the British and German ambassadors and thus d to smooth American relations with the belligerents. an. 1915 Wilson sent him abroad to study the possibility merican mediation. He suggested the principle of the eedom of the Seas," after visits to London, Berlin and Paris, possible step towards a compromise; but the sinking of the sitania" ruined all chances of success. In the autumn, se proposed that Wilson suggest to the Allies that a peace erence should be summoned; if Germany refused the con- ice or rejected terms calculated to ensure a just settlement, United States would enter the War on the side of the Allies nforce such terms. House left for Europe again in Dec. , visited England, Germany and France, and finally made aforesaid offer to the British, the substance of which was rporated in a memorandum drafted by Grey and himself. Allies, however, refused to take advantage of it.

the summer and autumn of 1916 House took an influential in the campaign which led to Wilson's re-election. At the of the "Sussex" crisis and the German Peace Note of Dec. , his private negotiations with Bernstorff were of high im- ance. After the United States entered the War, he kept in touch with the chiefs of the war-making agencies, and was onsultation with the special envoys of the Allies: Balfour, thcliffe, Tardieu, Reading. In the autumn of 1917 Wilson ed him chief of the special American mission designed to rdinate Allied war needs, especially the problems of finance, ly, tonnage and man-power. The conferences in London Paris which he attended proved to be the turn of the tide. r his return he was intimately concerned in Wilson's drafting he Fourteen Points, and at the request of the President he ted a tentative covenant for a League of Nations, which ned the basis of Wilson's later plan. In Oct. 1918 Wilson him to Paris to represent the United States at the Allied ncil which granted an armistice to Germany.

fter some difficulty, House succeeded in pledging the Allies to son's Fourteen Points as a programme for peace. He had viously organised "the Inquiry," a body of experts for ecting authentic data for the use of the Peace Conference. se was one of the U.S. Peace Commissioners signing the aty of Versailles, and although ill at the opening of the con- nce he played an important rôle by reason of his intimacy with opean statesmen. He was a member of the commission that ted the League of Nations' Covenant, and ultimately most he details connected with the formation of the League were led with his co-operation. In July and Aug. 1919 he represented the United States in the organisation of the Mandates system. After his return to the United States he urged President Wilson, by letter, to compromise with the Senate so as to secure ratification of the Versailles Treaty and the entrance of the United States into the League. A serious illness, coming at the same time as the physical breakdown of Wilson, combined with other factors to interrupt the close relations between the two men which had persisted since 1911.

Col. House had won a reputation for such sagacity and disinterestedness that his advice was continually sought by political leaders even after the overthrow of the Democratic party in 1920. Arthur Griffiths asked that he be named arbiter in the Anglo-Irish dispute. He continued his interest in international questions and maintained close relations with the ruling statesmen of Europe.

In 1912 House published, anonymously, a political romance, *Philip Dru;* in 1921 he edited (with Charles Seymour) *What Really Happened at Paris*, a series of essays on the Peace Conference written by members of the American Delegation. He also wrote, after 1920, a number of articles upon contemporary politics and political leaders for *The Philadelphia Public Ledger*, *Foreign Affairs*, *Harper's* and *The Encyclopædia Britannica*.

BIBLIOGRAPHY.—*The Real Colonel House*, by A. D. Howden Smith (1918), a brief but accurate biography covering House's career to 1918; *The Intimate Papers of Colonel House*, arranged as a narrative by Charles Seymour (1926). (C. SEY.)

HOUSEHOLD APPLIANCES.—The working equipment for the household has achieved a new importance in recent years. In the 19th century, labour-saving machinery was adopted in industry; the 20th century has witnessed a progressive application of such machinery to the work of the household, the most important advances falling within the period following 1910. This change is little indebted to the initiative of the housekeeper herself, although a growing desire for the elimination of drudgery, together with a scarcity of domestic help, has provided an incentive to the engineer and manufacturer to meet this need with numerous mechanical devices.

The wide adoption of such appliances has owed much to the increasing availability of electricity for power and to the development of automatic machinery and standardised methods of production. A large part in their distribution has been played also by advertising, demonstrations in stores and the home and similar methods employed by manufacturers to make known their products. A number of manufacturing and distributing plants, including gas and electric-light companies, especially in the United States, are now maintaining home-service departments directed by women trained in home economics.

Schools and colleges, and also government departments, have been giving attention to the subject of household appliances during recent years in the United States, Canada, Great Britain and, to some extent, in other countries. A significant factor in this development of household devices, in some of the English-speaking countries, has been the work accomplished by enterprising home magazines that have established service bureaux, and also laboratories for the testing and investigation of household appliances.

ELECTRICITY IN THE HOME

The outstanding feature in the development of household appliances, during the period under review, 1910–26, has been the greatly extended use of those operated electrically. This fact in turn has had an important bearing on one aspect of house construction, namely, the wiring, which is increasingly ordered with a view to the use of electrical appliances. This involves the installation of a large number of appliance outlets, properly placed, instead of a limited number of lamp sockets. In districts where electricity is very cheap, houses are being wired with circuits of high current capacity to provide for electric ranges and certain other cooking devices which cannot be used on ordinary circuits. There has been a general improvement in the fittings or fixtures, such as switches, sockets, plugs, etc., the restrictions of regulatory bodies having helped to maintain minimum standards which in practice have been exceeded by the better manufacturers. Attachment plugs have largely been standardised, thereby ensuring the same interchangeability in appliance connections as appertain to incandescent lamps. In the United States the parallel blade plug is superseding all others.

The electric curling iron is reputed to be one of the oldest, if not the oldest, of electrical appliances. In 1926, however, the electric flat iron had a far greater sale than any other electrical appliance. The electric toaster leads in the field of small table devices, but there are many others which find a place in the kitchen or dining-room, such as percolators, table-stoves, grills, hot plates and waffle irons. The general use of nickel chromium resistance wires, introduced about the year 1910, assured the practicability and therefore the beginning of a really extensive use of electric heating appliances. These alloys can be heated to redness in the air without oxidation and the physical properties of ductility and malleability they possess permit the fabrication of heating units in a wide variety of designs. The popularity of electrical heating devices owes much to the ease with which the heat may be regulated, and this is often automatically accomplished, notably in ranges, flat irons, warming pads and percolators, by means of thermostats, which may either limit the temperatures or keep them at the desired level. In some cases additional controls are provided to start and stop the current at predetermined times. In certain central house-heating plants an electric motor controlled by a thermostat operates dampers and drafts. If the fuel used is oil or gas the heating becomes, by this device, entirely automatic, but if coal is burned, refuelling is necessary. (*See* HEATING AND VENTILATION.)

Small Motors.—Among the more important factors in the wider application of electricity to household appliances has been the perfection of light-weight, efficient motors. The motor of small size and light weight has made possible portable electric vacuum cleaners, electrically driven mixers, floor-polishers, coffee-grinders, knife-sharpeners, sewing-machines, etc. Sewing-machines designed for the incorporation of a motor are portable, light in weight and easy to operate. In motor design the important problem is lubrication, because, in the household, motors frequently go unoiled for relatively long periods and their use is intermittent, often being confined to an hour or two each week. It is now customary to provide oil-wells of relatively large capacity, which do not need replenishing for long periods. In many instances ball bearings are provided, packed in grease, so that lubrication will not be required, perhaps for the life of the device, or at least until some other parts need attention or replacement, when the ball bearings can be repacked.

The tremendous increase in the use of electrical appliances in the United States during recent years has been due, in no small degree, to the almost complete standardisation of the type of current furnished for consumer supply, namely, 110 or 120 volt 60-cycle alternating. Direct current is mainly confined to a few large centres, where its use is economically feasible. In many other countries a lack of a standardised current has placed almost insurmountable obstacles in the way of a general use of electrical appliances in the household. An indication of the rapidity with which they have been adopted in the United States is afforded by the fact that the number of electric vacuum cleaners in use rose from an estimated figure of 18,000 in 1910 to 5,000,000 in 1925. In the same period the number of electric washers increased from 3,000 to 3,500,000. The number of houses wired for the use of electric current rose from 2,934,900 in 1910 to 13,406,777 in 1925. Incidentally those equipped for the use of gas increased from about 5,000,000 in 1910 to 10,720,646 in 1925.

THE EQUIPMENT OF THE KITCHEN

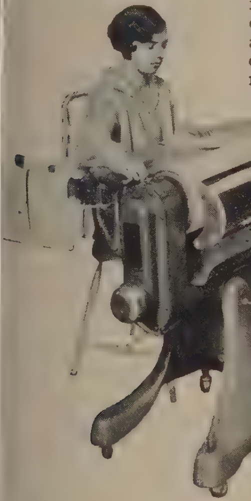
As regards the kitchen the present trend is in the direction of a smaller kitchen, used only for the preparation of food. In the smaller modern apartments the kitchen has become a kitchenette, with more wall space than floor space. This fact as well as the desire to obviate unnecessary motions, has led to careful planning in the arrangement of the refrigerator, w cabinet, range and sink. The working surfaces at sink, ra work-table and kitchen cabinet have been raised to a he better adapted to the worker, that found most generally s able for the sink being 34 in. from working bottom to the f The kitchen cabinet, as a valuable space saver, is grow steadily in favour in the United States, Canada and poss in a few other countries. More recently these cabinets h been supplemented with additional storage units, a cupbo and a broom unit. Thus equipped, the cabinet really br the storage pantry to the work-table and provides comp and convenient storage space. While it would be sounder gineering practice, as applied to the kitchen, to have in s all tools and materials needed for daily use, popular taste parently objects to having utensils hanging uncovered on ho beside the proper working centre, or to seeing food contai on open shelves. Kitchen cabinets are, therefore, all provi with doors, behind which equipment and food materials stored. These cabinets are available in so-called built-in un which may include a refrigerator, storage and broom cupbo and may be installed to form part of the permanent fitting the kitchen. Cabinet cases and their accompanying units usually finished in either white or grey enamel, and nearly cabinets have porcelain-enamelled iron table-tops, usually constructed as to permit being drawn out for use and pus back within the general body of the cabinet when not requi

Porcelain-enamelled iron linings have become very common refrigerators. The most noteworthy development in dome refrigeration has been the increasing use of mechanical units supplant ice. In the United States and Canada up to the p ent time the actuating part of the unit has been almost ex sively of the compressor type operated by an electric motor. some European countries machines operating on the so-ca expansion principle are coming into use. In these machi there is no motor, the compression of the gas refrigerant be accomplished in closed vessels through the application of he The source of heat is usually gas or electricity. Sinks are usu ly provided with drainboards frequently cast in one piece w the sink, the material used being porcelain-enamelled ir porcelain or vitreous china. Combination faucets for hot a cold water have proved very convenient. As steps toward m ing the precision of the laboratory possible in the kitchen, capacity of kitchen measuring cups has been standardised a thermometers have been specially designed for registering t temperature of the oven, of the fat in deep frying and of s ups in home candy-making.

Ranges.—Ranges are frequently equipped with thermost for the automatic control of oven temperatures. In both g and kerosene ranges, there has been a marked improvement the construction of the burners, making possible better co bustion. In England the "all-gas" kitchen, in which g is used for cooking, heating and water-heating, is a develo ment of the years 1915–26. The cabinet type of gas cook or range, in which the oven is located adjacent to the coo ing top, has become common in England and in the Unit States. Some electric and gas ovens have been constructed utilise the principle of the fireless cooker, by which baki is done on retained heat. Another development is the i proved insulated gas-range oven, designed for the greater co servation of fuel. Porcelain-enamelled iron is used for the e terior of gas ranges, and some have oven linings of this materi

Fireless cookers have been improved by the use of aluminiu linings and by the employment of heated radiators produci oven temperatures for baking, the latter innovation necessitating safety valve in the cover of the cooker to provide for the esca of steam, thereby avoiding danger of explosion. A later d velopment was the electrically-heated cooker. The pressu cooker is employed for canning and for high-altitude cooker In this device, the steam generated is confined within the coo ing utensil and, by the increased pressure, raises the boilin point of the liquid. Cooking, therefore, takes place mo rapidly and with a consequent economy of fuel.

Laundry and Cleaning Equipment

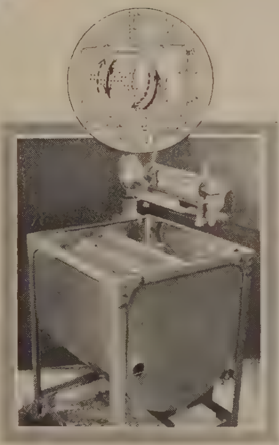


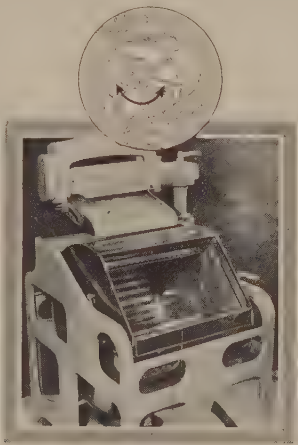
'his ironing-machine has an electrically heated shoe and ıe padded roll is revolved by a small motor. The operaor's right hand is on the lever controlling the mechanism that moves the shoe away from or up to the roll. Mechanically operated ironers are rapidly superseding the older types of machines which require considerable exertion on the part of the operator in order to bring the roll and shoe together against the action of the springs which maintain the pressure. Similar household ironing-machines use gas for heating the shoe instead of electricity.

The floor scrubbing and polishing-machine above has a ¼ horsepower motor mounted on a circular base. The motion of the motor shaft is transmitted by gears and a chain drive to a brush or polishing pad under the base.

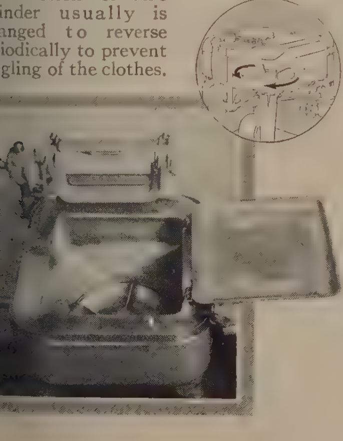
In electric suction cleaners air, moved by a motor-driven fan, enters the floor nozzle carrying dirt into a fabric bag which retains the dirt as the air passes through the pores of the bag. Generally a tractor or a stationary brush is fitted to the nozzle. Other cleaners have a brush in the nozzle revolved by the motor. Another type has a combination agitator and brush which taps the floor covering to loosen the dirt.

iously there are many
's to produce the relative
ion between clothes and
er necessary to flush the
out of the fabrics and in
way wash them. As a
ural result many different
es of washing machines
e been developed. The
hine at the right represents
cylinder type, in which
hes are placed in a cylindri-
container having perforated
s or ends and transverse
fles to lift the clothes as the
nder revolves. The cyl-
er is revolved about its axis
another container holding
er to a depth about half
between the bottom of the
inder and the axis.
e-motion of the
inder usually is
anged to reverse
iodically to prevent
gling of the clothes.

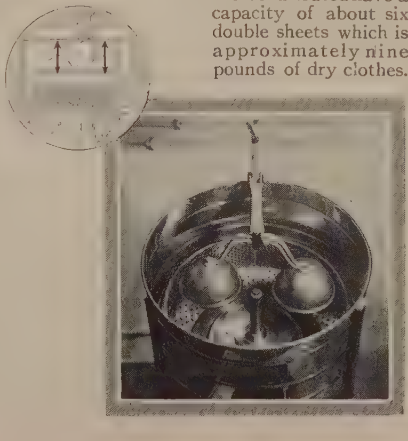




The machine illustrated at the left is an oscillator washer. In machines of this type the clothes are placed directly in the water in a tub that generally is shaped somewhat like a cube with two of the ends rounded. The tub is rocked or oscillated on its transverse axis so that the water and clothes are tumbled about in the washing process. Both machines at the left have power-driven wringers, the direction of rotation of the rolls being reversible and the wringer being movable about the support so that it may be used in any one of several positions, such as wringing from tub to basket. Washing-machines similar to these illustrated have a capacity of about six double sheets which is approximately nine pounds of dry clothes.



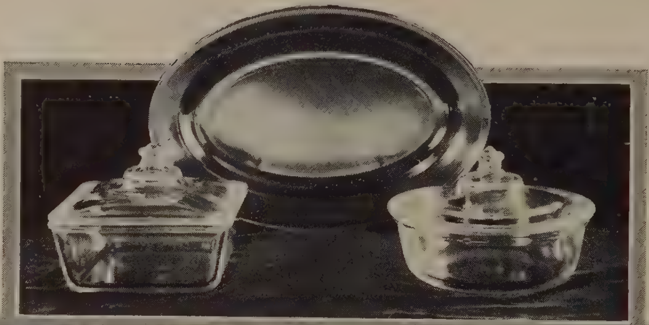
The washer, at left, has a tub of square cross section with rounded corners. The washing action is produced by a dasher or gyrator, a circular plate having vertical vanes or paddles. The clothes are dragged back and forth through the water, and the water is rather violently agitated by the gyrator as it rotates around the vertical axis. This machine has a power wringer.



In the machine at the right, the inverted hollow hemispheres are moved up and down in the clothes and water contained in the cylindrical tub. This action is typical of so-called vacuum cup washers. The one illustrated has no wringer, the drying being accomplished by centrifugal extraction. During the drying operation the inner basket is spun about the vertical axis at high speed.

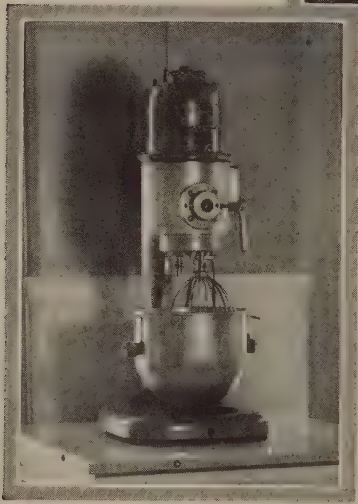
Kitchen Equipment

A lighting fixture, adapted to kitchen or laundry, designed to give proper diffusion and distribution of light with a high brilliancy incandescent lamp.

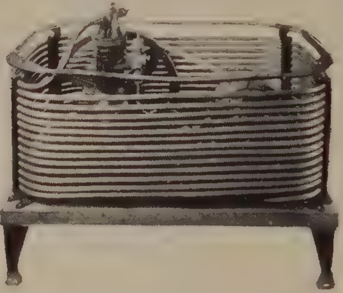


Glass of special composition which will withstand oven temperatures is being used extensively for oven cookery in casseroles, baking cups, platters and other suitable forms.

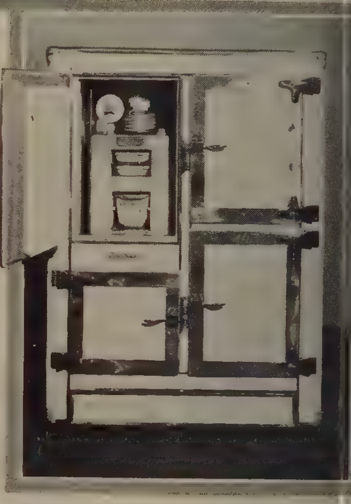
Advantages of the steam pressure cooker are economy in time and fuel. It has important applications in cooking at high altitudes, and for canning.



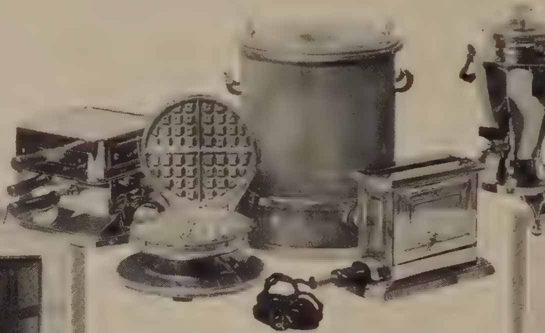
This beater and mixer is operated by the motor at the top which, through gears, drives two vertical spindles below, to which whips or beaters may be attached. A horizontal shaft drives other attachments such as coffee grinder, food grinders, ice chopper and ice-cream freezer. Three speeds are available.



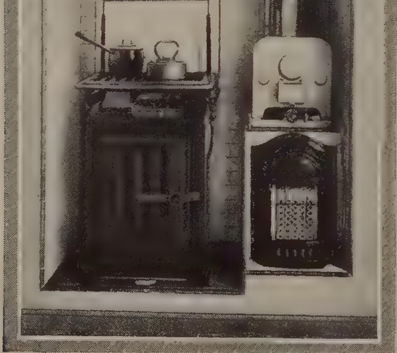
The motor-driven compressor compresses a gas refrigerant that becomes liquid in the condenser coil. The liquid is expanded in a coil in the refrigerator absorbing heat from surroundings. Expanded gas passes to intake of compressor and cycle is repeated.



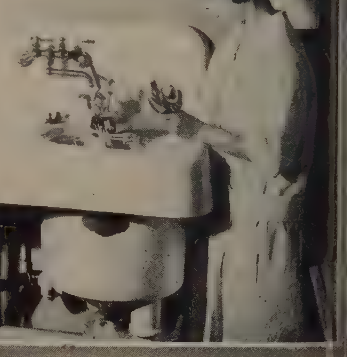
The tank in this refrigerator is the portion of the refrigerating unit which takes the place of ice. In it is a coil through which passes the refrigerant, such as sulphur dioxide, methylchloride, ethyl chloride, propane or isobutane. Outside of the coil is brine or other liquid having a low freezing point.



The appliances shown above include, from left to right, table stove, waffle iron, insulated cooker, toaster, and coffee percolator urn. All of these are electrically heated.



To the left is an English "all gas" kitchen having a cooker or range, a gas fire or room heater and a boiler or water heater.



The dishwasher at right is motor-operated and part of a kitchen sink. The motor is connected with a vertical shaft which projects through the bottom of the tank. On top of the shaft is a dasher to splash water over the dishes held in suitable racks. A cover is provided to reflect the splashed water over the dishes. There is a valve-controlled drain to the house waste pipe.

e dish-washer, both non-electric and electric, although lable for some years, has been slow to meet with popularity. epends on the action of a spray of hot water over the dishes, motive force being provided either by water pressure from ucet or by an electrically-driven agitator immersed in water. etal dish-drier, valuable in the saving of time and in the pos- ties for sanitary dish-washing, has not yet come into as ral use as it deserves. A machine of many uses in the kitch- the electric beating and mixing machine. It has a variety ttachments for various types of work. Among the minor ces of value should be mentioned stainless steel cutlery, developed in England (*see* Rustless Steel); oven-proof ; and a foot-lever attached to garbage cans, by which the r may be operated without the necessity of any stooping on part of the user.

Cleaning and Laundry Work

e scrubbing brush is being eliminated partly through ges in floor coverings and surface finishes, which lend them- s to easier cleaning methods, and partly through improve- ts in cleaning devices. The push-broom has come into wide the brooms with stout, heavy fibre being largely replaced acuum sweepers for cleaning carpets and rugs. Brushes ecialised design and material have been adapted to a large ber of different uses, the bristles varying in stiffness, size arrangement and the shape and handle being adjusted to unction for which the brush is intended. There is a tendency eplace wood by metal for the backing of such brushes. An rtant labour-saving device is a scrubbing brush rotated n electric motor, which may be used for polishing waxed s.

acuum Cleaners.—The first vacuum cleaners were hand- ated and were of the pump type. An electric cleaner, in- uced a little before 1910, was made by attaching a motor e of these hand-machines. In other machines a centrifugal directly attached to the motor shaft, replaced the suction p. Increased efficiency of the motor and fan has permitted at reduction in the size and weight of the cleaner. There wo general classes of cleaners: those relying on suction and depending mainly on a motor-driven brush. Those of the class clean by creating, through and across a floor covering, rent of air, which is carried through the cleaner by revolv- an and takes the particles of dust with it to be deposited e a bag provided for the purpose. Some of these so-called cuum cleaners" are provided also with fixed brushes inside tside the nozzle or with revolving brushes within the nozzle, notion of the brush being transmitted by the wheels on h the machine travels. These machines are distinguished the second type by the fact that the action of the brush condary in importance to that of the air current. In the d type, called "suction sweepers," the brush itself, re- d by motor, does the major part of the work, agitating loor covering in such a way as to loosen the dirt. The suc- produced by a fan raises the floor covering to the mouth e nozzle and carries the dirt into the bag. Various attach- s may be used with electric cleaners for cleaning cushions, lstered furniture, draperies and other surfaces.

undry Equipment.—Although primitive equipment and ods of laundering are still widely used, modern laundry ods are gradually driving out those century-old pieces of ment—the washboard and the boiler. These are not necessary achine-washing, when there is available a supply of hot r and soaps in flake and chip form or in cakes. The f stationary tubs, made of glazed porcelain or porcelain- elled iron, is becoming more common and, as in kitchen ment, tubs and ironing boards are being raised to a more ortable minimum working height. The use of the com- ion faucet for hot and cold water is increasing. Washing- ines, both hand and power-operated, are to a considerable t supplementing the stationary tubs. The electric wash- achine was first used a little before 1910, and by 1926 was her general use in the United States and Canada.

The purpose of all washing-machines is to drive the soapy water through the soiled clothes with sufficient force to wash out the dirt. In the so-called "dolly," one of the earliest types, the clothes are dragged back and forth through the water in a tub by means of prongs or pegs projecting into the tub from a base that is moved first in one direction and then in the other around its vertical axis. The sides and bottom of the tub are generally corrugated, so that there is something like a washboard action as the clothes are dragged back and forth by the prongs. A second type might be called the "pump circulating type." It consists of a tub in which a water-pump operated by an electric motor maintains the circulation of water, and the clothes are carried around and kept continuously in motion by the circulating stream. Another type has several paddles mounted on a plate in the bottom of the tub. It moves first in one direction and then in the other around its vertical axis, swirling the clothes and water back and forth.

The vacuum-cup, or suction, washer has two, sometimes three, cups shaped like inverted funnels or hollow hemispheres, which move up and down so as to plunge down into the clothes and water and force the water through the clothes. There is a constant shifting of the relative position of cups and clothes to ensure thorough washing. The oscillating type of washer consists of a tub generally shaped somewhat like a cube with rounded ends, in which a rocking action keeps the clothes in motion.

In the cylinder, or rotary-type, washer the clothes are placed in a perforated cylinder supported in a tub containing water. The cylinder revolves in one direction and then reverses, repeating this regularly, thereby keeping the clothes in a backward and forward motion over strips of wood or metal along the inner surface. Washing-machines often have power-driven wringers attached. Among the improvements introduced into the wringer is the use of semi-hard rolls, to prevent breaking of buttons and serious injury to the fingers of the operator if accidentally caught between the rolls. There is also a type of washer fitted with a centrifugal drier instead of a wringer in the form of an inner perforated container, which revolves rapidly, throwing the water out of the clothes. For filling these power-machines and emptying them there are fillers and drainers, working with a syphon action. Labour is saved, however, by having a supply of hot and cold water piped directly to the machine with a piped outlet for waste water. This arrangement involves having the machine permanently installed in the house. Clothes driers heated by gas are available for indoor drying, and indoor clothes racks have been ingeniously designed with a view to economy of space.

Ironing Machines.—The ironing-machine (formerly called mangle) was first operated by hand and, not being heated, accomplished its work entirely by pressure. The power-driven heated ironing-machine was developed in the United States about 1910. Both gas and electricity may be used for supplying heat, and mechanical control is, in some cases, now substituted for manual control. The larger machines have a roll length of about 48 in. and the smaller ones of about 28 inches. Water-softening plants are sometimes installed for use with household laundries to meet the problem of softening hard water.

Heating and Ventilating

In a large number of homes electrically-driven fans have long been used to give a cooling breeze in the summer. It is becoming more generally recognised that fans may be advantageously used in winter to improve the circulation of air in a closed room or to assist in direct ventilation to outdoors, thereby ridding the air of smoke or vapour. A specialised fan has been designed for attachment in window frames of kitchens for the purpose of ridding the room of cooking odours.

Auxiliary room-heaters, utilising the easily controlled fuels, are in common use. Gas heaters, of the so-called radiant type, have been making big strides in this field. They were first used in England, where they were practically always placed in front of a coal fireplace. Later "built-in" gas grates were introduced, and these have greatly increased in use. These grates take up less floor space and require a much smaller flue than the coal fireplace. Kerosene heaters, mainly taking the form of a large kerosene burner set in a suitable case having a steel drum for radiating heat, find frequent use in the autumn and spring to take the chill from one or more rooms and to help the main heating plant in periods of extremely cold weather. Electric-heaters of the radiant type are in general use, but more extensive development in electric house-heating appliances has been prevented through the relatively high cost of electricity in comparison with other available fuels.

Water-heaters.—In assuring a supply of hot water for household uses water-heaters play an important part as labour-saving appliances. One of the older methods for obtaining hot water where plumbing was installed was the provision of a hollow cast-iron section or water-back for one side of the fire-box of the kitchen range, this section communicating with a tank for storing the hot water. A similar method uses a coil or pipe inserted in the fire-box of the house-heating furnace or boiler and communicating with a storage tank. These methods of heating water suffer from the disadvantage that they cease to function when the furnace is not being used and when some other fuel is used instead of coal in the kitchen range. One of the cheapest methods of obtaining an abundant supply of hot water in the coal-burning regions of the United States is a small stove especially designed for the purpose of communicating with a water-storage tank. Gas is used extensively for heating water, sometimes in addition to a water-heating attachment to the house furnace. There are several types of gas water-heaters, the simplest consisting of a gas burner placed below a coiled pipe or cast-iron water-container attached to a tank by two pipes to permit circulation of water through the coil or container. This type of heater is frequently known as the side-arm heater. It is generally designed to be operated whenever hot water is desired, but attachments are made so that it can be converted into a thermostatically controlled heater to maintain a constant temperature in the storage tank. Another type of control is of the clock variety, so arranged that the gas flame will be extinguished after the burner has been in operation for a definite time, which can be varied as required. Another type of gas water-heater is simply a combination of gas burner and storage tank with automatic temperature control, known in the United States as the automatic-storage type. To avoid loss of heat during idle periods the tanks of these heaters are heavily insulated with such materials as corrugated asbestos paper, in layers sometimes $1\frac{1}{2}$ to 2 in. thick, mineral wool, ground cork, etc. An adjustable thermostat controls the burner, which has a pilot light burning continuously.

The so-called instantaneous type of gas water-heater is controlled by the opening and closing of any hot-water faucet on the pipe line attached to the heater. This control is effected by means of a hydrostatic valve, which operates through differences in pressure. When all the faucets on the hot-water line are closed the conditions of pressure on both sides of the hydrostatic valve are such that the latter remains closed, but when any faucet is opened, the release of the pressure operates the valve, which in turn opens the gas valve supplying the burner.

Kerosene or coal-oil water-heaters are in use in districts where gas is not available. The majority of these heaters are practically identical in principle with the side-arm gas water-heater already described. Some kerosene water-heaters, however, consist of a complete unit of tank and burner. This unit has a thermostatic control, which extinguishes the burner when the water in the tank reaches a certain maximum temperature. Electric water-heaters have not come into very general use because they are comparatively expensive to operate, unless electricity is very cheap. They are easy to control, the heating elements do not require oxygen as do the burners of any device depending upon combustion, and there are no products of combustion to pollute the air. The efficiency, also, can be made relatively high, because the heating elements may be immersed directly in the water.

HOUSING (*see* 13.814).—Even before the outbreak of War
problem of sanitary and suitable housing deeply engaged the
tention of all persons interested in promoting the welfare of
population, especially of the working classes. The populatio
modern large towns had risen very rapidly through influx f
outside, and the working classes in particular were crowded
gether in narrow, over-populated quarters. Thus a chief ai
pre-War housing reform was the construction of cheap w
men's accommodation, together with the clearing of the
slums. The methods of this reform hardly went beyond the
vision of easy building credits and cheap sites, the reductio
building costs, the systematic planning of new residential
tricts, and the encouragement of co-operative building activ
The ideal form of dwelling, the so-called garden city, which a
at giving every family a beautiful and healthy home surroun
by a garden, could only be realised in a few model examp

I. A GENERAL SURVEY

Apart from the so-called "public utility building," which ai
at no profit beyond a normal and fixed return on capital, al
all building activity before the War was conducted by pri
enterprise. The margin of profit was arrived at by estimating
difference between the sum necessary for amortisation of
capital invested and the proceeds of the annual rent, after
duction of all taxation and costs of repairs, upkeep and admi
tration. This margin was not as a rule very high, but represe
a secure income for the landlord-proprietor; experience
shown this to be one of the safest of all forms of investment.

Changes During the War.—The World War brought first a
ing-off of demand, followed later by a very rapid increase in
costs of building, which reduced and finally abolished altoge
the return on capital in new buildings. Moreover the econo
weakness of states and individuals made it impossible to a
rents to rise at the same rate as building costs. The raisin
rents on this basis was almost always countered by the state
restrictive legislation, partly out of consideration for the fam
of the soldiers called up for active service and partly in the b
that the universal and increasing rise of prices was only a t
porary phenomenon. It seemed advisable, therefore, to let r
form an exception to this rise; this was achieved by prohibi
the raising of rents, either in all dwellings or in partic
categories of them. This prohibition was regularly supplemen
by other restrictions, such as prohibition of notice to quit. T
there arose in almost all European countries a special tenant
tection legislation, which imposed artificial restraints on
natural development of prices on the housing market.

Thus arose the difference between the rent paid for old dw
ings and the economic rent of new dwellings, a difference so g
that tenants could not pay for dwellings in new buildings.
at the same time rents, kept stationary at the pre-War level,
lost so much purchasing power in view of the general ris
prices that they often barely sufficed to cover the costs of
most necessary repairs. In most cases they no longer counte
a source of income for the landlord-proprietor. Thus pri
capital withdrew from building activity, as it could find m
more profitable application in many other branches of product

Housing Shortage.—Therefore a demand for housing accom
dation, which grew suddenly and rapidly, especially after
War, was confronted with a complete lack of supply of
dwellings. Moreover, the housing accommodation to han
on the decrease, since little or no renovating or repairs had
carried through for several years. Since it was impossible in
countries suddenly to let rents rise at one bound to a level w
would make the construction of new dwellings completely
nomic, there was no resource but to draw the necessary buil
capital out of national resources through other channels
those of free initiative.

State and Municipal Assistance.—States and municipa
were forced to spend on this object, under various headings
in various degrees, in part even by an actual subsidy of bui
activity. They took over the payment or guaranteed
ment for interest, redemption charges, amortisations and re

it of advances for building purposes, granted loans from lic funds, either free of interest or on easy terms; and granted -repayable building subsidies (in the form of premiums, sub- es *à fonds perdus*, etc.), either to cover the annual interest redemption charges or to cover the so-called "non-recover- building costs," *i.e.*, that part of the capital invested in ding on which interest and amortisation cannot be obtained.

ocial Aspects of State Assistance.—This far-reaching financial stance of building activity enabled the public authorities to l certain social requirements in the dwelling houses which helped to erect. Public assistance in building was as a rule ined to the construction of small dwellings and workmen's ses, subject to the fulfilment of certain minimum conditions social, hygienic and ethical nature and usually assistance was given to the "public utility" building activity of the local horities and co-operative societies. Only in its later stages this public assistance extended to include private building vity, and then mostly on the pre-War lines of remission of tion and of credit facilities. As, however, the resources ch could thus be applied to the construction of new dwellings , even so, usually insufficient to meet the actual demand, it ned imperative to supplement them by measures controlling ing housing accommodation.

ost-War Housing Policy.—Post-War housing policy may be divided into three groups of measures, under the head- : "tenant protection," "distributive" and "productive ing policy." Rents in existing dwellings should only be raised degree justified by the general economic situation and the ral ability of the population to meet them. This ideal can be realised when the conditions governing notice to quit be regulated at the same time (tenant protection). Since low encourage an uneconomic utilisation of existing accommo- on and, combined with the restrictions on notice, make an stment of the housing market difficult, it is necessary to re proper utilisation and just distribution of existing dwell- accommodation through official supervision (distributive ing policy). The systematic encouragement of direct build- ctivity becomes a task for legislation and administration, as ined above (productive housing policy). Although tenant ction and distributive housing policy are essentially excep- l measures which infringe on the liberty of the individual spose of his property, they have nevertheless lent a charac- ic stamp to the housing policy of almost all European states.

nant Protection.—Tenant protection assumed different s in different legal systems. In countries where fixed-period s are customary (France, Belgium, Italy, Rumania, the Can- f Geneva), the extension of the period of lease was secured w in some cases, in others left to the decision of special rent liation offices or tenant protection commissions composed of ords' and tenants' representatives in equal numbers. untries where leases are regularly contracted for indefinite ds and are terminable by notice (Central and North Europe) ght of giving notice is legally restricted, subject to the legiti- interest of the landlord (personal requirement), on condi- that the tenant can find another suitable dwelling; offences mitted by the tenant (arrears in payment of rent, disturb- of the peace, sub-letting without approval, etc.); or con- ations of public interest (alteration of the house, official rement of accommodation, etc.). In Germany, the right to notice has been abolished altogether and replaced by appli- n to a court of law for termination of the lease. Tenant pro- on has also often been extended to the increasingly common of sub-tenancies. Special provisions for periods of grace in of notices to quit are designed to eliminate, where possi- ompulsory evictions, which are undesirable if only in the st of public peace.

striction of Rents.—Measures for the protection of tenants ub-tenants against increases of rent have varied widely in ent countries according to the intensity of the housing age. In many of the neutral countries (*e.g.*, Holland, Spain) issions were set up, usually giving equal representation to rds and tenants, to consider whether a disputed increase of rent was justified. Other countries (England, France, Belgium, Italy, the Scandinavian countries, etc.) went further, introducing legislation or regulations by which certain categories of tenants or dwellings where such protection seemed advisable were liable to increases of rent only on a fixed graduated scale. In determining the percentage of increase, the taxable value of the house, the average expenditure necessary for its upkeep, etc., were taken into consideration. According to the country's general housing policy, the tendency was apparent, in greater or lesser degree, to bring rent gradually into line with the general level of prices and thus clear the way for the removal of rent restrictions.

The countries most severely affected by the housing shortage, especially those of Central and Eastern Europe, sometimes even reached the stage of making every increase of rent illegal, on the principle of placing the whole question of fixing rents on an exactly defined legal basis and thus abolishing freedom of contract in rent questions. As these were the very countries where the devaluation of currency with its devastating economic consequences appeared in its acutest form, the adaptation of the real rent, which had often sunk to a minute sum, to the new monetary conditions, formed a particularly difficult problem.

Allocation of Existing Dwellings.—These are the countries which were forced to take the most drastic measures in their distributive housing policy. In western countries, the authorities generally confined themselves to prohibiting the demolition of dwelling-houses, the utilisation of dwelling-space for other than dwelling purposes, the use of two or more dwellings by one occupant, etc. In many cases, too, permits to enter and settle in a district were introduced to restrict the liberty of moving (especially in Switzerland and Czechoslovakia) in order to secure the available dwelling-space for the native population. In some cases strangers were excluded from the benefits of tenant protection.

In the countries of Central and Eastern Europe, where the housing shortage was worst, housing policy even resorted to the radical measures of official requisitioning and allocation of available dwelling-space. Here again the interpretation of the word "available" varied sensibly. In some cases only dwelling-room which was actually empty or easily dispensable was subject to these measures, in others the dwelling-space allowed per head, or rather, the number of heads allowed per dwelling-room was fixed by law, and every dwelling-room beyond this was requisitioned and allocated to persons requiring accommodation (Germany, Austria, Czechoslovakia). Such measures were not far from the socialisation of dwelling-space, as actually practised in Hungary under the Communist régime and in Soviet Russia, where the Govt. carried its principle of "condensing" housing so far, that not only dwelling-rooms, but also unused corners of rooms were requisitioned and officially occupied. Even so, the housing crisis in Russia surpassed that of the worst-situated of the European countries.

Economic Effects of Rent Restriction.—The allocation of requisitioned dwelling-space presupposed a just and rigorous classification of the applicants according to the urgency of their needs. An entirely new and very responsible administrative branch was therefore created in public, especially municipal administration, which created an expensive and intricate apparatus (housing offices). The economic consequences of the restriction of rents in comparison with those of before the War was a far-reaching alteration in the utilisation of the national income. Of the enormous sums which had formerly been employed in the form of rent to pay interest and amortisation of the capital invested in dwelling-houses and to maintain the stock of dwelling-houses, only a small fraction was now applied to the same end. In this way the capital invested in dwelling-houses was partly consumed without any compensation being received. How far this was the case in the different countries is best seen from the table on the next page, which shows the percentage expenditure on rent in the total cudget of a workman's family before and after the War.

But a closer observation of the consequences of rent restrictions seems to show that the alteration in the distribution of the national income goes far deeper than is apparent at first sight, *Percentage Expenditure on Rent in the Total Budget*

Country	Pre-War	July 1922	July 1924
Denmark	14·2	11·14	11·22
Norway	15·7	11·40	11·30
Sweden	11·9	11·2	12·38
Switzerland	10·4	9·9	9·88
Great Britain	16·0	13·7	13·76
Finland	11·8	10·3	11·92
France	12·0	7·2	6·60
Italy	11·4	4·34	6·84
Germany	18·0	0·34	10·62
Austria	14·6	0·66	1·18
Poland	18·1	3·44	5·07
Hungary	18·0	0·22	0·77

and that the relative expenditure on different objects of the working population in particular has been deeply influenced by the fall in rents. For it became the almost universal practice to determine wages by reference to the general level of prices, so that the real wage of the workman, that is the purchasing power of his wage measured in commodities, should remain essentially stable. In reckoning the general level of prices, rent was considered as a factor. The workman who only paid in real value half as much or less for his dwelling as before the War, could therefore be content with a proportionately smaller real wage without impairing his general standard of life.

In view of the fall of the national income in many countries, this reduction of the workman's real wage, while not perceptible to himself, was perhaps actually necessary, at any rate advisable as making cheaper production possible. In any case, similar consequences of the rent restrictions also had their effect on the income and relative expenditure of other classes of the population. It became impossible to find paying tenants, especially for new working-class dwellings erected at greatly increased cost. They could not therefore be built with any prospect of a return on the capital invested, and were not built at all except where the state or the municipality intervened with assistance from public funds. But even this fund was modest in comparison with the capital which had been employed before the War in erecting dwelling-houses. A further consequence of this rent policy has been therefore a change in the application of the available national capital.

Modification of Restrictions.—Under these circumstances, all countries which did not aim at complete destruction of the value of housing property as a step towards socialism began to feel the need of restoring normal economic conditions in the housing market and of gradually raising rents into line with the general price level. The legislative methods adopted, the so-called "modification of rent restrictions," varied greatly in different countries; it was a general rule that the dwellings of the poorer classes were affected last by the rise in rents, and only quite gradually. Some governments found it expedient not to restore to the house owners that part of the national income which the increases of rent had rediverted into its former channels, but, after covering the expenses of repairs, upkeep and administration, to reserve the remainder as "rent duties" for public ends, either the construction of new dwellings for the most necessitous classes of the population, or else (as, for example, in Germany) for the general financial reconstruction of the state. In any case, since the raising of rents, if severe shocks to the economic system are to be avoided, must almost always be distributed over a long period, the capital necessary for new building had to be drawn from other sources than private capital seeking investment.

Other Methods of Financing Building.—The application of public money to housing is generally confined within as narrow limits as possible. Attempts have often been made to induce employers to help in raising the necessary means. Building subsidies from public funds have often been made conditional on the employers' providing subsidies of an equal amount. Some countries (*e.g.*, Yugoslavia) have even imposed a legal compulsion to build, on well-to-do individuals and firms who have been obliged at their own expense to provide by building for the accommodation of themselves, their families and their employees.

Reduction in Costs.—Another important way of bringing t rent of new dwellings into correspondence with the means tenants is by reducing the cost of building. This can be do by using less expensive forms of construction, employing cheap materials, standardising and typifying certain elements of t house. In almost all countries architects, engineers and contra tors have been occupied with these questions. In England, t Govt. has made elaborate enquiries in this direction, and h recommended certain useful new types of building. Attemp have been made to reduce building costs by co-operative me ods. Encouraged by many municipal authorities and by t trade unions, guilds, building organisations and social buildi enterprises have sought to solve the financial problem by eli nating profit and increasing output. But surrounded as they a by a world organised on non co-operative lines, they ha achieved no more than partial successes. No new method, new system has been fully successful in combating the housi crisis. The qualitative elements in housing—the improvement hygienic, ethical and social standards—have to be conside under the head of CITY PLANNING.

II. HOUSING IN VARIOUS COUNTRIES

The neutral states of Europe naturally suffered least from housing crisis consequent on the World War. Nevertheless, th did not wholly escape it, and, in fact, the Scandinavian sta Holland and Switzerland all adopted a more or less extens tenant protection policy. These countries, however, suffe very much less than the belligerents from the stoppage of bui ing; in none of them did building cease altogether. Therefore th could set about filling up their gaps much sooner. Holland is only country besides Spain in which extensive building activ since the War has already brought the end of the housing sho age in sight.

Countries of Western Europe.—Those victorious states wh found wide stretches of their country in ruins at the end of War had to reconstruct many thousands of ruined houses. I gave a welcome opportunity within the narrow limits of finan possibility of realising as far as possible the ideas of the hous reformers by building small family houses in garden settleme Remarkable successes have been achieved on these lines in the constructed districts of Northern France, Belgium and It Poland and Yugoslavia have also carried through the work reconstructing their devastated districts with much succ In Belgium, the *Société Nationale des Habitations à Bon Mar* with its wide network of local organisations, has done excell work in public utility housing construction, and financial ass ance has been given by the State.

In Italy legislation for the *case popolare ed economiche* has b of great importance, whereas the French housing action ba on the legislation *pour les habitations à bon marché* does not pear to have given really satisfactory results, although con erable financial assistance has been given and a great appara of offices and *sociétés d'habitations à bon marché* establish Great Britain has attacked her housing problem with m greater energy and correspondingly greater success, as wil seen in the article on the following page.

Germany and Austria.—Most states of this group have b compelled to requisition housing accommodation. The meth adopted were often influenced by political tendencies. T degree of success depended mainly on the economic capabil of the different countries. Germany suffered a severe hou crisis as an effect of the depreciation of her currency, though spent large sums from public funds and inaugurated a r successful housing policy in many industrial districts, *e.g.* the Ruhr. The particular character of her housing problems met by the organisation of housing offices, official control of exchange of dwellings, the assistance of rural building from funds of the so-called "productive unemployment relief" construction of miners' homes out of the proceeds of a dut coal, self-help associations such as the Lüneburg "Notgem schaft," building guilds, state-assisted limited companies erecting dwellings for dismissed employees, etc. Germany's cy aimed at raising rents in comparatively rapid stages to r pre-War level; the landlord-proprietor receives, however, so much of this increase as will correspond to the revalua- of mortgages in progress in 1925.

he housing shortage in Austria brought with it a strict tenant ection policy. In Vienna, rents were kept down in a way ch amounted to expropriation of the landlords in favour of tenants. The municipality of Vienna then itself took over building activity for the city, covering the deficit which it rred out of general and special taxation (rent tax).

ther Countries.—The more favourable financial situation of other succession states enabled Czechoslovakia and Yugo- ia especially, both to undertake state-assisted building vity on a much larger scale and to resume private enter- e. The reduction of war and emergency measures dealing tenant protection and distributive housing policy is already advanced in these countries, as also in Hungary, Poland, nania, Bulgaria and Greece.

Russia, the change of system in general economic policy in brought a return to more fruitful methods of housing policy r the original epoch of municipalisation and socialisation out, however, bringing noticeable relief. The European sing shortage thus presents a problem of such extent that, iew of the continuous increase of the population, it will be before it vanishes from the order of the day. (K. P.)

OTE.—The above sketch is based chiefly on the volume *European sing Problems since the War*, published by the International our Office, Geneva (1924).

nited States.—Housing conditions in the United States ely parallel those of European countries. The conflagration however, is greater, due to the large use of wood in the truction of dwellings. On the other hand, the much more ral use of modern systems of plumbing, heating and lighting es for greater comfort. The relative newness of American s means that they are less harassed by the survival of lete types of dwellings. The problem of slum demolition is efore not as acute or as prevalent as in Europe.

e National Housing Assn., established in 1910, and directed Mr. Lawrence Veiller, has promoted the study of local ing conditions and the framing of state housing laws and housing ordinances. Approximately 100 local housing sur- have been made in the last 20 years, most of them ting in improvements of local housing conditions. State- surveys made in California by the State Commission of igration and Housing and in New York State by the mission of Housing and Regional Planning are especially worthy.

gislation.—The revised edition of Lawrence Veiller's Model sing law has been used as the basis of housing acts in a number of states and cities. The Recommended Minimum uirements for Small House Construction of the United States t. of Commerce, prepared by a special committee with the eration of Dr. John M. Gries, Chief of the Division of ding and Housing, are widely used as the basis for building s, and that division has played an important rôle in pro- ng building, housing and zoning legislation and in providing ral information on these and kindred subjects.

gencies of Improved Construction.—Among the scores of lim- dividend companies for improved housing, the City and rban Homes Co. of New York City is conspicuous for the nsiveness of its building operations. The Metropolitan Life rance Co. and the Bayonne Housing Corp., with the aid of ew J. Thomas, architect, have made notable advances in ment house architecture, especially in planning for sunlight. most striking of recent developments in row and group ing have been made by the City Housing Corp. of New City in their Sunnyside development and by the Bridgeport sing Assn. at Bridgeport, Conn., and the Octavia Hill Assn. iladelphia. The garden community designed by John Nolen lariemont, near Cincinnati, O., although not designed for -earning families, is the best recent example of community ning with detached housing.

Co-operative Housing.—A movement for co-operative ownership of apartments has been cultivated by the National Assn. of Real Estate Boards. The only important recent venture in co-operative suburban housing is that of the Garden Homes Co., near Milwaukee.

Industrial Housing.—Several hundred American industrial corporations have provided industrial villages or extensive improved housing developments for their employees. Among these should be mentioned the U.S. Steel Corp., which has built in scores of communities; the General Motors Co. at Flint, Mich.; the Goodyear Tire and Rubber Co. at Akron, O.; Norton Co. at Worcester, Mass.; the Mount Union Refractories Co. at Kistler, Pennsylvania and the Ford Co. at Detroit.

Governmental Housing.—In the United States the building of houses is left to private enterprise. During the World War the Federal Govt., through the U.S. Housing Corp., the Emergency Fleet Corp. and the War Dept. built many thousands of houses in well-planned communities, as an emergency measure. These projects have since been disposed of by sale to individuals or corporations. They have, however, served to interest many leading architects and town planners in the problem of industrial and suburban housing, and thus have led to improvement in general standards of industrial housing.

Housing Finance.—There is no provision by the Federal or state governments for public loans for small-house construction. The recent attempt by the state of North Dakota to provide such loans has been pronounced unsuccessful. The construction of private dwellings is largely financed through building and loan associations, which are semi co-operative in their organisation and methods. In 1924 there were 11,844 associations of this character, with a membership of over 8,500,000 persons, and total assets amounting to over $4,700,000,000.

Educational Agencies.—In 1922 Better Homes in America, Inc., was established by Mrs. William B. Meloney to organise local committees to study and improve local conditions of housing and home-life. Under the leadership of its president, Herbert Hoover, Secretary of Commerce, this organisation in 1926 formed 2,937 committees in cities, towns and villages throughout the United States. These committees have arranged lecture and discussion programmes, contests for home improvement and demonstrations of the better types of small house architecture, furnishing and landscaping.

The Architects' Small House Service Bureau, established by the American Institute of Architects, has contributed greatly to the improvement of prevailing standards in small house planning and design by issuing hundreds of plans of single-family houses of from three to six rooms. Such plans, with specifications and quantity surveys, are sold at nominal cost to families throughout the United States who are interested in building homes of their own. (J. F.)

III. HOUSING IN GREAT BRITAIN

Despite legislation during the preceding 50 years or thereabouts, housing of the working classes throughout England and Wales in the census year of 1911 was far from satisfactory. Economic facts mainly account for the paradox of surplus accommodation (5·6%) existing in conjunction with some 250,000 families surplus to structurally separate dwellings; 405,010 tenements of four rooms and less were occupied by more than two persons in one room. Insanitary areas and unfit houses abounded. The conditions in Scotland were worse. Local authorities, even later than 1890, with few exceptions, did not consider that housing the people fell within the essentials of their activities, and up to 1909 a legal obligation existed to sell, within 10 years, houses erected in discharge of rehousing obligations.

Unregulated and speculative individual effort dominated this branch of the building industry to the extent that some 95% of pre-War working-class accommodation was built by private enterprise. Increasing cost of production operated to diminish output until fear, inculcated by the taxation of land, produced by the Finance (1909–10) Act, dried up the sources of speculative house building. The dangers due to increasing population cribbed by inadequate and wasting accommodation failed to secure national recognition, although private bills to stimulate production by subsidy were introduced unsuccessfully from 1911 to 1914.

Thus the outbreak of the World War in Aug. 1914 found housing in arrear. War conditions, causing large migrations and increased marriages, rapidly absorbed vacant accommodation in the cities. Rent Restriction Acts controlling rents and preventing evictions, but aggravating slum conditions, followed. Normal upkeep of houses was checked, and new construction was suspended by military requirements. Production and import of building materials ceased, and the ranks of skilled labour became depleted. The end of the War revealed a deplorable condition. The perpetual housing problem due to poverty had been intensified, and accommodation was lacking for many whose capacity to pay was undoubted. It was estimated (1918), possibly in excess of the immediate effective demand, that a deficiency of approximately 500,000 houses existed, of which 109,000 were needed in Scotland.

The census of 1921 later revealed 760,543 families in England and Wales surplus to structurally separate dwellings. The replacement of unfit dwellings to an approximate amount of 205,000 was not included. In addition, the London County Council required 29,000 new dwellings and immediate clearance of insanitary areas involving rehousing of 40,000 persons. It is noteworthy that nevertheless health statistics were good.

The problem presented was incapable of rapid solution. Skilled operatives were reduced by 50% as compared with 1908, and the remainder absorbed in maintenance and by contract builders. Material was scarcely procurable. An unparalleled financial stringency prevailed, with cost of living of wages and of material increased by over 100% on pre-War figures. The working classes, which constitute about three-fourths of the population, mainly require houses let at weekly rents. Even if building for sale were feasible, to let at an economic rent was impossible.

The Act of 1919.—In these circumstances the Coalition Govt., stimulated by the slogan "Homes for Heroes," rapidly passed the Housing, Town Planning, etc., Act 1919. This epochal Act embodied three principles: an obligation on local authorities to effect housing schemes, a State subsidy to housing and stringent penal clauses relating to compensation payable for insanitary property. The State shouldered all liability on approved schemes exceeding a 1d. rate borne by the local authority. The standard of housing was raised, but the incentive to local extravagance, countered by paralysing departmental centralisation, combined with exclusion of private enterprise, marred the Act. Prices soared until an annual loss per house of £50, to be met throughout the loan period of 60 years, was not uncommon. The average cost, exclusive of London, in 1920 was £860 for non-parlour and £972 parlour type. Nearly £100 must be added to building prices for land, roads and sewers. In London it cost as a minimum £158 per person housed as compared with £43 per person pre-War, and the average per habitable room in a tenement block attained £375 comparable with less than £100 pre-War. A total of 174,540 houses excluding some 3,000 temporary huts was the result of the Act at a (Treasury) cost of about £175,000,000, exclusive of the 1d. rate borne by the local authorities.

The Act of 1919.—The Housing (Additional Powers) Act 1919 remedied the exclusion of private builders, to whom a lump sum subsidy averaging about £240 a house was given, which provided nearly 40,000 houses at a total cost to the Government of £9,493,155; it forbade conversion or demolition of dwelling houses, and, to conserve labour for dwellings, attempted prevention of "luxury" building; the latter prohibition proved more injurious generally than beneficial. Both output and cost were seriously affected by the trade unions of this sheltered industry, which defeated all attempts to increase production by a dilution with ex-service men or otherwise. The results attained by the 1919 Act were not commensurate with the cost. Therefore in June 1921 the Government curtailed the scheme to "the number built, building or for which tenders have been approved," and notified a contribution not exceeding £200,000 a year for the improvement of insanitary areas in England a Wales. The suspension of the Act led to a fall in prices, and a va hope of abolishing subsidy was entertained in some quarters. T average cost (excluding London) in 1922 for non-parlour type w £362 and with parlour £393. By 1925 prices had reached £440 a £495 respectively, but in 1923 it was deemed expedient to enac limited subsidy (£6 a year for 20 years) for houses or flats of specif dimensions and containing a bath. The (Chamberlain) Act succ fully aimed at promoting private enterprise and owner-occup both by subsidy and loan. The Small Dwellings Acquisition 1899 was extended and co-operation with public utility and build societies sought. Up to the end of 1925 over 278,484 houses been arranged for under the Acts of 1923 and 1924, of which 151, were completed.

Acts of 1923 and 1924.—Before the 1923 Act could become operat the advent of a Labour Govt. led to fresh legislation, to *pari passu* with the 1923 Act. After conferring with the build industry and the local authorities a financial basis was agreed between taxpayer and ratepayer. The former was to pay twic much as the latter, viz.: £9 and £4 10s. respectively, for 40 ye and any remaining gap between cost of production and inc should be filled by rent from the tenant. Heretofore rent fixat had proceeded on the basis of comparable accommodation in neighbourhood: now special conditions were attached on the b of pre-War rents as amended by Rent Restriction Acts. This w diminish rent where production costs were low. In agricultural ishes, of defined limits, the subsidy was raised to £12 10s. becaus the special difficulties of rural conditions. The Housing (Finan Provisions) Act 1924 propounded a fifteen years' programme, ject to biennial revision of contributions, under which 2,500, houses should be provided; an apprenticeship scheme, under w the ratio to craftsmen was increased to one in three, instead of unattained permitted maximum of from one in four to one in se was an essential adjunct of the Act. But an apprenticeship sch requires several years before fruition, and augmentation of cr men was overdue.

The continuing shortage of skilled labour led to investigatio new methods and materials for cottage construction. Conc speedily established itself as a substitute for brick, but the neces of eliminating plasterers' and bricklayers' work evolved novel ty notably the factory-made "steel" house. Progress in such has been hindered by the hostility of the building industry and timidity of local authorities.

Consolidating Act of 1925.—The permanent law relatin housing was consolidated into the Housing Act 1925, and attached table shows progress up to the end of that year. In London area progress was retarded by special difficulties, ma due to London's magnitude, the population being eight t that of Birmingham, the next largest city (excluding Scotla and the inaccessibility of housing sites.

The housing problem is not solved, and the economic posi now as ever, refutes the idealistic standard of one dwelling family, every family a dwelling. It will take much expend and many years of persistent national endeavour to achie practical standard enabling all capable of paying a mod rent to occupy a structurally separate dwelling, to establi margin of surplus accommodation, to suppress overcrow and to abolish insanitary areas and unfit houses. But a post lies in an adequate supply of skilled labour, and a measu town planning applied to built-up areas is indicated as a corol

Pre-War Number of houses provided	Greater London	England and Wales (including Greater London)	Scotlan

OUSMAN, ALFRED EDWARD (1859–), British poet scholar, was born March 26 1859 and educated at Broms- ve School and St. John's College, Oxford. From 1882–92 ıeld a post in the Patent Office, and then became professor of in at University College, London, until 1911. He filled the ınedy Chair of Latin at Cambridge from 1911 onwards, being elected fellow of Trinity College. His editions of Manilius ɔ3–20) and of Juvenal (1905) are well known to classical ɔlars, but he is most widely famed as the author of the lyric ıence, *The Shropshire Lad* (1896), a work with few rivals of kind in the language. His only other published volume oetry was *Last Poems* (1922), which showed a command of cate cadence and a fine sensibility no less distinguished than se of his early work.

OUSSAYE, HENRY (1848–1911), French historian (*see* 28), died in Paris Sept. 23 1911. After his death were pub- ed *Iêna et la campagne de 1806* (1912), and *La patrie guer-* (1913). See L. Sonolet, *Henry Houssaye* (1905).

OUSTON, Texas, U.S.A. (*see* 13.828).—A few years after the rld War, Houston became a world port, with 33 steamship s in 1925 operating regularly to the principal ports of North South America, Europe and the Orient. Its total tonnage xports, imports and coastwise traffic (1924) was 5,343,598 s, valued at $294,796,871. The first bale of cotton was orted in Nov. 1919; shipments for the season 1924–5 were 1,828 bales. The 25-ft. ship channel, completed in 1914, deepened to 30 ft. and widened between 1919–25. Un- an enabling Act, passed in 1921, the navigation district Harris co. assumed operation of the port and made ex- sive improvements in port facilities. The projected intra- stal canal from the Mississippi river to the Houston Ship nnel will connect the port with 6,000 m. of inland waterways. value of manufactures within the city limits was $23,015,000 909; $86,874,000 in 1919; $89,133,777 in 1923. The area was cased from 17·4 sq. m. in 1910 to 36·5 sq. m. in 1920 and to q. m. in 1925. The population in 1920 was 138,278, of whom 60 were negroes and 12,088 foreign-born; in 1925 it was nated at 164,954; the local estimate for the metropolitan rict was 250,000. Between 1920 and 1925 great progress was le in paving and widening streets, constructing sewers and ges, improving the fire department, building driveways along bayous, adding parks and beautiful public buildings and ısforming the business section with modern office buildings hotels. Rice Institute opened for its first academic year on t. 23 1912 in buildings on its 300-ac. campus.

OWARD, LELAND OSSIAN (1857–), American ento- ogist, was born at Rockford, Ill., June 11 1857. He gradu- l from Cornell University, becoming B.S. in 1877 and M.S. 883. After serving as assistant entomologist at the U.S. ɔt. of Agriculture, Washington, D.C., in 1878, he was made f of the Bureau of Entomology in 1894. From 1904 he was sulting entomologist in the U.S. Public Health Service, and n 1895 honorary curator of the U.S. National Museum. was in 1917 a member of the committee on agriculture and irman of the sub-committee on medical entomology of the ional Council of Defence.

oward wrote *Mosquitoes—How They Live* (1901); *The Insect* k (1902); *The House Fly—Disease Carrier* (1911); a monograph mosquitoes for the Carnegie Institution (1912); and many ernment bulletins.

OWELLS, WILLIAM DEAN (1837–1920), American novelist 13.839), died in New York May 11, 1920. In 1915 he ived the gold medal of the National Institute of Arts and ers for his work in fiction. To within a short time before his h he continued to contribute to the "Editor's Easy Chair" *larper's Monthly*. His later works included *My Mark Twain* o); *Imaginary Interviews* (1910); *Parting Friends: a Farce* 1); *Familiar Spanish Travels* (1913); *New Leaf Mills: a* *onicle* (1913); *The Seen and Unseen at Stratford-on-Avon: a* *tasy* (1914); *The Daughter of the Storage and Other Things in* *se and Verse* (1916); *The Leatherwood God* (1916); and *Years* *My Youth* (1916). In 1920 he edited with an introduction *The Great Modern American Stories.* He left unfinished *Years of My Middle Life.*

HRDLIČKA, ALĚS (1869–), American anthropologist, was born at Hampoletz, Bohemia, March 29 1869. His early education was received in Bohemia. He studied at the New York Eclectic College becoming M.D. in 1892. In 1894 he joined the New York State service, investigating the insane and other defective classes, and became in 1896 associate in anthropology in the State Pathological Institute. He was a member of the Hyde expeditions to Mexico and the southwestern United States in charge of physical anthropology, 1898–1903. In the latter year he was appointed assistant curator in charge of the division of physical anthropology at the U.S. National Museum, Washington, D.C., becoming curator in 1910. As a member of various anthropological expeditions he made researches in many parts of the globe. He became a leading exponent of the theory that the North American Indian is of Asiatic origin. Among his works are *The Eskimo Brain* (1901); *Ancient Man in North America* (1907); *Ancient Man in South America* (1912); *Anthropological Work in Peru* (1914).

HROZNY, BEDRICH (1879–), Czech orientalist and archaeologist, studied in Prague, Vienna, Berlin and London. In 1904 he took part in the Seelin excavations in Ta'anuk (north Palestine), on the basis of which he wrote *Die Keilschrifttexte von Ta'annek* (1904) and *Die neugefundenen Keilschrifttexte von Ta'annek* (1906). In 1905 he was appointed professor at the University of Vienna, and in 1919 became professor of cuneiform research and ancient Oriental history at the Charles University of Prague. Hrozny's name became known chiefly in connection with the study of the ancient Hittites. He left the solution of the Hittite hieroglyphics to chance, proceeded to work on the basis of Hittite documents from the Boghazkoi archives written in cuneiform script, and in 1915 thus succeeded in deciphering the Hittite language, which he proved to be an Indo-European tongue, closely akin to the Iranian, Celtic, Italic and Slavonic families of speech. His solution was attacked from many quarters, but he substantiated his claim by the success with which he read and translated a number of documents, among others a Hittite legal code (published in Paris, 1922, under the title: *Code Hittite provenant de l'Asie Mineure, I. Partie: Transcription, traduction française*). In 1925 excavations for the purpose of further research were made under his direction by a Czech scientific expedition to Asia Minor.

HUBAY, EUGENE DE (1858–), Hungarian composer and violinist, was born at Budapest Sept. 15 1858. His first teacher was his father, who was a professor of the violin, as well as a composer and conductor. From 1871–5 he studied in Berlin under Joachim, and later, on the recommendation of Liszt, gave successful violin recitals in different countries including England. While in Paris he was associated with Vieuxtemps and Massenet. In 1882 he succeeded Wieniawski as professor of the violin at the Brussels Conservatoire, and in 1886 was appointed to a similar post at the Budapest Academy, of which he has been the director since 1919. His pupils include many eminent violinists, among them Vecsey, Jelly d'Aranyi and Szigeti. Hubay has written the following operas: *The Violin Maker of Cremona; Anna Karenina; Alienor; Die Maske; Moosröschen; Lavottas Liebe*, etc. His other compositions include symphonies, violin concertos, and solos and songs. His early works, based on Hungarian and French elements, were exclusively lyrical, while his later compositions show more dramatic rhythm as well as more modern tone-colouring.

HUBER, MAX (1874–), Swiss lawyer, was born Dec. 28 1874 at Zürich. He became doctor of law at Berlin University in 1897 and, on the conclusion of his studies, travelled extensively and made a prolonged sojourn in the Far East. From 1902 to 1921 he held a law professorship—first extraordinary and subsequently ordinary—at the University of Zürich. In 1921 he resigned his chair and became honorary professor. The Swiss Federal Council on many occasions consulted him as an expert in international questions and he was a Swiss representative at the Hague Conference in 1907. During the World War he was legal adviser to the Swiss Political Department. In this capacity he was entrusted with several missions to the Peace Conference, to the League of Nations and to various governments. In 1920 and 1921 he was deputy delegate to the Assembly of the League of Nations. He was a member of the Jurists' Committee of the Council of the League of Nations dealing with the Aaland Islands question and of the International Blockade Commission. He became both a judge of the Permanent Court of International Justice and a member of the Permanent Court of Arbitration.

HÜCH, RICARDA (1864–), German poet, was born in Brunswick July 18 1864 and educated there. Later she studied in Zürich, where she took her degree. She was appointed secretary of the library in Zürich and married first Dr. Ceconi, and later Dr. Richard Hüch, a lawyer. She wrote a number of romantic and imaginative novels, among which may be mentioned *Aus der Triumphgasse* (1902); *Vita Somnium Breve, Ein Roman* (1903); *Der grosse Krieg in Deutschland* (1912–4); and *Der wiederkehrende Christus* (1925). Her most important historical works are *Blüthezeit der Romantik* (1899); *Ausbreitung und Verfall der Romantik* (1902); *Das Risorgimento* (1908). In 1919 appeared a volume of reflections, *Der Sinn der heiligen Schrift*, which reveal a profound knowledge of psychology.

HUDSON, WILLIAM HENRY (1841–1922), British naturalist and writer, was the son of Daniel Hudson (1804–68), who was himself born of English parentage at Marblehead, Massachusetts. W. H. Hudson, Daniel's third son, was born at Quilmes, near Buenos Aires, Aug. 4 1841, and remained with his family on the pampas until about the age of 29, when he came to England. From then the greater part of his life was spent in poverty, and his difficulties were accentuated by frequent ill-health. His wife, Emily, long kept a boarding-house in London, where Hudson too lived, known to only a small circle of appreciative friends. A civil list pension granted in 1901 aided him somewhat, but he voluntarily relinquished this in later years when belated success reached him. He died in London Aug. 18 1922 and was buried at Broadwater, Sussex. His writings include the memorable pictures of the South America of his youth, such as *The Purple Land* (1885); *A Crystal Age* (1887); *El Ombú* (1902); *Green Mansions* (1904); *Far Away and Long Ago* (1918); of the English countryside, such as *A Shepherd's Life* (1910); *Dead Man's Plack* (1920); and the posthumous *A Hind in Richmond Park* (1922); ornithological works, as his collaboration with P. L. Schlater in *Argentine Ornithology* (1888–9); and his own *British Birds* (1895); and *Birds of La Plata* (1920); and many pamphlets for the Society for Protection of Birds. A bird sanctuary with a decoration by Jacob Epstein was erected to his memory in Hyde Park, London, in 1925.

See H. J. Massingham, *Untrodden Ways: Adventures among the Works of Hudson, etc.* (1923); Morley Roberts, *W. H. Hudson* (1924).

HUGEL, FRIEDRICH VON, Baron (1852–1925), Catholic theologian, was the son of Karl von Hugel (1775–1870), Baron of the Holy Roman Empire, a German by birth, an Austrian subject, and Austrian minister to the grand ducal court of Tuscany at Florence where on May 5 1852 Friedrich was born. Baron Karl had married Elizabeth Farquharson, a convert from Presbyterianism to the Catholic Church. In 1867 the family went to England and made their home at Torquay.

Friedrich von Hugel's education was curiously miscellaneous: brought up a Catholic, he was early made acquainted with Anglican forms and doctrines; from 8 to 15 he had a Rhenish Prussian Lutheran tutor, whom he loved, the Catholic historian Alfred von Reumont meantime supervising the course of the teaching; to his father perhaps he owed a turn for science, studying geology and entomology. Hebrew he learnt from a Rabbi and from the Catholic priest—Professor Gustav Bickell, the Biblical critic and commentator on Job. This singular upbringing, his mixed ancestry and his knowledge of languages, together with his natural gifts helped him to become one of the most sympathetic, resourceful and persuasive religious teachers of his age, and won him many friends in many lands. He took into his purview all history, all races, all religions, all philosophies, all literature. But while he possessed a generous sympathy
for all seekers after truth, he held the Catholic Church to poss
in its creeds, worship, history and institutions, the fullest, ri
est and deepest realisation of religion. He accepted the Pap
and the principle "*ubi Petrus ibi ecclesia*," but at the same ti
he thought that the government of the Church was ov
centralised, and he believed that the bureaucratic tendency co
be counteracted by the healthy interaction of energy between
head and the members of the whole body of believers.

His Biblical scholarship led him into relations with the Hig
Criticism and he accepted what he regarded as the assured res
of such studies. This association with modernist Biblical cri
led him to be classed with Modernists. When the crisis of M
ernism was over, he made it more and more clear that frien
and sympathetic as he was to them, as to all others who w
troubled by doubts, he could not follow the Modernists who
volted from Rome and that he rejected altogether their the
of belief. He wrote that the main spiritual influence, dating fr
1886, which had strengthened his faith, had been the teach
and the example of the Abbé Huvelin, a remarkable French pri
who wrote no books but "wrote in souls." Baron von H
himself brought out no book until he was fifty-eight. A lette
The *Times Literary Supplement* of May 25 1922 on L
Duchesne is of value for its treatment of the subject, but
as an apologia for the Baron's own religious belief.

In 1873 the Baron married Lady Mary Herbert, a daugh
of Sydney Herbert (Lord Herbert of Lea). He died in Lond
Jan. 27 1925 and by his own wish was buried in Downside Abb
Bath, Somersetshire. He asked that his library should be giv
to St. Andrews University. In his will are the words "I de
to die as I have striven to live, a devoted member of the Cath
and Roman Church."

His works include: *The Mystical Element of Religion as studie
St. Catherine of Genoa and her Friends* (1908, new and rev. ed. 19
Eternal Life, a Study of its Implications and Applications (1
2nd ed. rev. 1913); *The German Soul in its Attitude towards Et
and Christianity*; *The State and War* (1916); *Essays and Addresse
the Philosophy of Religion* (1921).

HUGGINS, MARGARET LINDSAY, Lady (1848–1915), Bri
astronomer (*see* 13.857), died in London March 24 1915.

HUGHES, CHARLES EVANS (1862–), American law
and statesman, was born at Glen Falls, N.Y., April 11 1
He attended Colgate University from 1876 to 1878, whenc
proceeded to Brown University (B.A., 1881; M.A., 1884).
studied law at Columbia University, taking his LL.B. degree
1884 and obtaining a prize fellowship at the Columbia law sch
In the same year he was admitted to the New York bar,
engaged in practice till his appointment as professor of la
Cornell University in 1891, a position which he relinquishe
1893 in order to resume practice. He continued, however,
maintain his connection with Cornell in the capacity of sp
lecturer, and, in addition, was a special lecturer at the
York law school from 1893 to 1900.

In 1895 he was retained as counsel for the Stevens Gas C
mission, appointed by the New York State Legislature to in
tigate the cost of gas; and in the same and following years
counsel for a committee of the New York State Legislat
known as the Armstrong Insurance Commission, formed
the purpose of investigating life insurance companies. In
he was nominated for mayor of New York City by the Re
lican convention, but declined to stand. In the coal invest
tion of 1906 he acted as special assistant to the Attorney-Ge
of the United States. In the same year he was elected Gove
of the State of New York, defeating William Randolph He
and was re-elected in 1908. He resigned Oct. 6 1910, on be
appointed Associate Justice of the Supreme Court of the Uni
States by President Taft.

Candidate for the Presidency.—In 1916 he resigned from
Supreme Court on being nominated for the presidency by
Republicans, but was narrowly defeated by President Wood
Wilson, who had been renominated by the Democrats. Hugh
election was considered assured when the campaign began;
though he "stumped" the country widely he disappointed

ple because he took no definite position on any of the specific stions involving the stand of America in the World War, and ecially as regards the sinking of the "Lusitania." The result he election was doubtful until a full count had been made, eventually hinged upon Minnesota and California, normally ublican states. Hughes carried Minnesota by a few hundred es, but lost California by a few thousand. The electoral vote 277 for Wilson against 254 for Hughes. The popular vote 9,129,606 for Wilson against 8,538,221 for Hughes. The owing year he again entered upon the practice of law in New k City. In 1917 he was appointed chairman of the Draft peals Board of New York City by Governor Whitman, and 918 he acted as special assistant to the U.S. Attorney-Gen- in charge of the investigation of alleged waste and delay in construction of aircraft. He was president of the New York Association in 1917–8, and of the Legal Aid Society 1917–9. was the leader of the New York Bar Association in its oppo- on to the expulsion of the Socialists from the New York State gislature in 1920.

s Secretary of State.—On the inauguration of President rding, March 4 1921, he became Secretary of State. One of first steps was to intervene in the Panama-Costa Rica dis- e respecting their boundaries. The two states had drifted actual hostilities, but on March 18 1921 Mr. Hughes advised m, in terms which practically amounted to an ultimatum, to ange for a peaceful delimitation of their joint frontier—a sug- tion which they ultimately accepted. The Soviet Govt. proached him in his first month of office asking that the United tes should resume trade relations with Russia, but he promptly ected the Soviet proposals. Later on M. Chicherin communi- ed with him with a view to the recognition by the United tes of the Soviet Republic, but this also was refused, Dec. 1923.

n 1921 Mr. Hughes, under authorisation by President Hard- sent out invitations suggesting a conference on the limita- of armaments to be held at Washington. The conference held—Mr. Hughes being chief U.S. delegate—with the lt that seven treaties were negotiated relating to limitation naval armaments, the fortification of islands in the Pacific relations between China and other Powers (*see* WASHING- CONFERENCE).

n a speech at New Haven in Dec. 1922 Mr. Hughes dealt at gth with the matter of German reparations, and unofficially gested a committee of experts to investigate. This was the esis of the committee which ultimately prepared what is wn as the Dawes Plan (*see* REPARATIONS). The Tacna-Arica pute afforded another instance of Mr. Hughes's intervention behalf of peace (*see* TACNA-ARICA). It was largely due to Hughes's efforts also that a convention was signed between U.S. and British governments by which the U.S. authorities re permitted to search British vessels on the high seas within 2-mile limit from shore, the purpose being to prevent the uggling of liquor into the United States. One of the last acts Mr. Hughes before he retired from office was to suggest a ution of the controversies between Brazil, Colombia and u as to certain portions of their boundaries. A settlement effected in March 1925.

Mr. Hughes's attitude in respect of foreign affairs during his m of office was well set forth in an address entitled "The hway of Peace," delivered by him before the Canadian Bar ociation Sept. 4 1923. "The League of Nations," he said, y its constitution presupposed that peace could be maintained economic pressure and military force." He dissented from s, since he believed that there was no path to peace except as will of peoples might open it. The way to peace was through eement, not force. "There is no lawgiver for independent tes; the outlawry of war necessarily implies a self-imposed traint." Upon this hypothesis was consistently based his ole attitude towards world politics. He was, however, in our of the adherence of the United States to the World Court International Arbitration. The judicial impartiality of Mr. ghes's character fitted him admirably to succeed in handling the international problems confronting him as Secretary of State, but he lacked the dramatic and popular qualities which might have led to his choice as chief executive of the nation.

He resigned office March 4 1924 and retired into private life. He was, in the April following, elected president of the American Society of International Law. In 1925 he acted as chairman of the New York State Reorganisation Commission, appointed to investigate the structure of the State Government. The commission reported March 1 1926, urging that the 180 state bureaux and departments be merged into 18, and that an executive budget system be introduced.

In addition to numerous addresses, most of which have been reproduced in pamphlet form, Mr. Hughes has published *Addresses and Papers* (1908); *Conditions of Progress in Democratic Government* (Yale Lectures, 1910); *Addresses 1906–16* (1916); *Foreign Relations* (1924); and *The Pathway of Peace* (1925).

(H. W. H. K.)

HUGHES, SIR SAMUEL (1853–1921), Canadian soldier and politician, was born at Darlington, Ont., Jan. 8 1853. In the Fenian raids of 1870 he served with the Canadian volunteer militia, and in 1873 he was gazetted to the 45th Regiment. Educated at Toronto University, he lectured at a Toronto collegiate institute until 1885, when he took up journalism, being editor and proprietor of the Lindsay *Warder* from 1885 to 1897. In 1892 Hughes was elected to the Dominion Parliament, but service in the South African War interrupted his political career. Returning to Canada after the coronation of King George V. in 1911, he became Minister of Militia and Defence, and was chiefly responsible for the creation of the overseas force which sailed for Europe in 1914. In 1915 Hughes was created K.C.B. and promoted major-general; but in the following year disagreements with Sir Robert Borden resulted in his resignation. Hughes criticised severely the strategy and leadership of Sir Arthur Currie. In July 1921 he announced his intention of retiring from Parliament, and he died at Lindsay, Ont., Aug. 24 1921.

HUGHES, WILLIAM MORRIS (1864–), Australian statesman, was born Sept. 25 1864 at Llansantffraid, Montgomeryshire, Wales, and received his early education at Llandudno Grammar School. Moving to London, he became a pupil teacher at the Burdett-Coutts schools, Westminster, where he attracted the attention of Matthew Arnold, then an inspector of schools; and at the age of 20 he emigrated to Australia. Here he began a period of picturesque wanderings, which it would be hard to parallel in the life of any statesman, ancient or modern. He drove sheep and cattle across the vast spaces of New South Wales and Queensland, worked on farms and cooked for harvesting gangs, became a sailor on coasting steamers, prospected for gold, tramped from station to station doing odd jobs, mended everything, from umbrellas to locks and from ovens to violins, taught children in remote settlements, walked hundreds of miles organising for the Australian Workers' Union, and in the end drifted back to Sydney and gravitated, as was only to be expected from the bent of his mind and character, to politics. He formed the Sydney waterside workers into a militant organisation, and entered the New South Wales Parliament in 1894 as member for the Lang division of Sydney.

As a member of the Opposition Mr. Hughes had no chance of showing administrative ability, but he became known as an effective debater, and devised the Labour party's caucus system of settling all internal dissensions outside the House and presenting a united front in Parliament. Then in 1901 came federation, and as member for West Sydney in the first House of Representatives Mr. Hughes found the wider scope that his political genius demanded. In 1904 Mr. J. C. Watson formed the first Labour Ministry, and Mr. Hughes, who in the midst of his industrial and political work had found time to qualify as a barrister, became Minister for External Affairs. The Ministry was short-lived, but thenceforth it was clear to friends and foes alike that a new force had entered Australian politics. During the years that followed Mr. Hughes went on developing until the hesitating, ineffective speaker of the 'nineties became one of the most brilliant and powerful orators in the Empire, and his courage, energy, intellectual gifts and dominating personality made his succession to Mr. Fisher almost inevitable.

Mr. Hughes was attorney-general in the Fisher Ministry of 1908, and revealed not only a remarkable gift of eloquence and a mordant wit, but a breadth of view and a warm Imperialism hardly to be looked for in a party which, not so many years before, had toyed with the idea of "cutting the painter." He was largely responsible for the scheme of compulsory military service which later proved so valuable, and he was heart and soul with his leader when Mr. Fisher, who had returned to office after the Liberal defeat of 1913, made his historic offer in 1914 of Australia's last man and last shilling. In 1915 Mr. Fisher went to London as high commissioner, and Mr. Hughes, as his logical successor and the man to whom Australia looked for strong leadership in the dark days of war, succeeded him as Prime Minister. Thus this frail little man, who weighed only seven stone, who suffered increasingly from deafness and ill-health, and who had depended for higher education entirely on what reading he could find time for in the intervals of work ranging from the mending of kettles to the organising of strikes, had as his reward the highest honour that his countrymen could offer.

On the whole they were not disappointed. Mr. Hughes, by his driving force and faculty of kindling enthusiasm, gave an immense stimulus to the raising and maintenance of the Australian Expeditionary Forces; and with equal energy he devoted himself to the task of eradicating German commercial influence from Australia. Germany, he found, had almost a monopoly of the output of Australian mines, and German firms controlled even the supplies of metals needed by the British Govt. for munitions. By the end of 1915 he had brought forward legislation which annulled all German contracts, transferred control of output to the newly established Australian Metal Exchange, prevented trading with the enemy, and disinherited enemy shareholders in commercial enterprises of every kind. This was practical statesmanship of very real importance.

In the following year he visited England and attracted wide attention by preaching a renaissance of the British race based upon a greater development of the Empire's resources and a closer-knit economic system. Returning to Australia with the conviction that a stronger flow of reinforcements was needed, he attempted to introduce conscription. On this issue the Labour party split, and the result was that Mr. Hughes formed a coalition government composed of the Liberals and that section of the Labour party which followed him on the conscription issue. The conscription referendum, on which the Government was defeated, was marked by great bitterness, and there followed a period of industrial and political strife without parallel in Australia's history. Mr. Hughes was hotly attacked for his autocratic methods, for his excursions into state shipowning and shipbuilding, and for his policy of concentrating power in his own hands by means of the War Precautions Act, the establishment of boards to control industry, and the appointment of special tribunals to settle industrial disputes over the head of the Arbitration Courts. But so long as the War lasted there was no alternative leader acceptable to the people, and the Prime Minister left to attend the Peace Conference with his prestige higher than ever. His assertion of Australia's right to proclaim something rather like a Monroe Doctrine for the Pacific did a great deal to awaken Americans and the world to the importance of Australasia; and at Versailles his advocacy, as eloquent as it was dogged, of the Commonwealth's right to a mandate over the former German colony of Papua, helped to make history. His quarrel with President Wilson, embittered by mutual dislike, gave rise to some of the most piquant passages in the annals of the conference.

In Australia, on his return, Mr. Hughes found grave industrial troubles disturbing a country already weighed down by an immense load of debt and the problem of reabsorbing 400,000 men into civil life. In peace as in war he gave Australia a bold and brave lead, and a gift of £25,000, raised by private subscription, showed that some at least of his countrymen were not ungrateful. But he could not prevent discontent revealing itself in the secession of certain Liberal-Nationalists and the form tion of a new Country party. As the conditions which ha brought it into existence disappeared, the War party which led began to crumble, and in Feb. 1923, after holding office Prime Minister for eight years, he was forced by a Liberal-Cou try party coalition to resign in favour of the Treasurer, M S. M. Bruce. Then, a leader without a party, he stood asi and awaited his chance. (G. C. D.)

HULL, England (*see* 13.870), with a city area of 11,854 a including 2,495 ac. of the river Humber, had a population in 1 of 287,013. The port was enlarged in 1914 by the opening King George's Dock, with an area of 53 ac. and provision f future extension to 85 ac., a large grain silo and fine equipme The total water area of the docks is 236 ac. with 10 m. of qua The extensive and varied traffic of Hull was much affected the World War, as the city was in the area of the North S operations, but the volume of trade had almost recovered 1926. The numerous industries include a large production vegetable oil. There are some 300 steam trawlers in the fishi fleet, which did valuable service during the War. In 1914 t chief magistrate was created lord mayor.

New churches include St. Colomba's (1914), St. Mary Sculcoates (1916), St. Nicholas', Hessle Common (1915) and t German Lutheran church (1911). A Friends' meeting house built in 1919, a synagogue in 1914 and a large Wesleyan-Meth dist Hall in 1910. The City Hall and Municipal Art Galler were opened in 1910, and the Guildhall enlarged in 1915; a stat of the 1st Baron Nunburnholme was placed in front of the lat in 1913. In 1912 a home for incurables was built and a new po law hospital in 1914. During an air raid in that year some houses were wrecked and 24 persons were killed. The coun chamber at Trinity House, together with many art treasures, destroyed by fire in 1924. The Rt. Hon. T. R. Ferens, a be factor to the city in various directions, initiated in 1925 a fu for the establishment of a university college with a gift of £25 000. He had previously given land on Cottingham road, the outskirts of the city, as the site of a new technical colleg but this is to be made available for the university college.

HUMAN GEOGRAPHY.—Geography is defined (*see* 11.61 by Dr. Mill, as the exact and organised knowledge of the tribution of phenomena on the earth's surface. Human geo raphy on this view would be the corresponding type of know edge of phenomena relative to mankind. While it is possible bring in a great deal under this heading of distributional stu yet this does not express the aim towards which many worke have striven from at least the time of Herodotus onwards.

Ratzel, Vidal de la Blache and Herbertson.—Space cannot given for a historical survey, else we might discuss the sta points of thinkers of many centuries and regions down to Mont quieu, Humboldt, Ritter, Le Play, Buckle and Reclus. Ra reacted against writers who overemphasised personality in terpretations of history. He urged that in treatises touchi both history and geography the history was likely to expand duly. His anthropogeographic studies discuss especially human relations of natural features and his method has been veloped by Miss Semple into that of a study of influences geographic environment. Some workers on these lines ha failed to see how much of an "environment" has been made man's previous work. Vidal de la Blache made a special cont bution to the clarification of thought on human geography. him the study of place is the foundation and the place-relations modern life are the centre of interest. Proceeding from descri tion to interpretation, he was led to look upon those place-r tions as stages in long courses of evolution from the past towar the future. Indeed the realisation of the time factor is a gre feature in all his work.

He again has contributed markedly to the idea of man as agent modifying the world about him, influenced by the stage human action as he found it, but also doing much to make setting wherein his successors are to act their parts. One of typical statements may be rendered thus: "The personality a country, its *genius loci*, is not a matter given beforehand nimate nature, it is in large measure a product of the activity man, of an activity which confers a unity on matters that uld otherwise lack it," and again, " If a region has personality, has been gained through the effort of its successive inhabi- ts." He saw, as did Herbertson, that the *genius loci* changes th the spirit of the time. In a sense, then, the student of hu- an geography aims at picturing the settings of the stage of man activity at all places and at all times, even if he is primari- concerned with the present. If he limits himself by not looking ck to the past out of which the present has come, he is not ely to be able to glimpse the future arising out of the present, d his work will be still-born.

Evolution and Human Geography.—It is obvious from what s been said here that human geography is a daughter of Dar- nian thought, for Darwin brought to a head the problem of ations between organisms and environments and their in- ences upon one another, and for him also the present was but stage in the succession from past to future. The application d modification where necessary, of the thought brought to ition by Darwin, has occupied the minds of biologists ever ce. The stages of conquest of the land by backboned animals m fish-like beginnings up to the varied orders of mammals are ing worked out in ever increasing detail, and equally the dead- ds of evolution, the extinct orders, are followed to their dis- pearance.

The extension of Darwin's point of view to man has proceeded me distance, but, in the study of man's relations with his en- onment, that extension meets with difficulties largely because the highly varied fields of study, which must necessarily come, ether directly or indirectly, into consideration. Outlines of e progress of men's relations with their environments from the rliest days of stone to the latest days of steel are being worked t in many ways, and also, just as in the study of animals, dead- ds, such as the jungle-covered cities of Ceylon, the monuments Easter I., are receiving attention from many points of view, luding that of the geographer. At the same time, it is well at one should guard against too ready acceptance of theories determinist sequences in history such as those suggested by inders Petrie and Spengler.

Culture Origins.—It is unfortunately as easy as it is dangerous argue, largely *a priori*, that a given environment produces rtain results in human culture, and there have been thinkers o have argued that numbers of the more fundamental inven- ons such as metal tools, pottery, cultivated wheat, domestic ttle have been made independently in several regions as parallel sponses to the influences of those environments. Enquiry has rown doubt on several of these conclusions and many now ink that food production had one localised origin, while prob- ly the same conclusion is true for pottery (*see* ARCHAEOLOGY; CIAL ANTHROPOLOGY). The varying spreads of these main lk-inventions, probably quite as much by contacts as by mi- ations, have been important means of modifying men's rela- ons with their surroundings far from their place of origin. Thus introduced into the study of the setting of the scene of man's tivity a cultural-historical element, and geography is brought to close relation with folk-history. Geography studies the scene, story the sequence of the action, but both need the sister science anthropology in its widest sense, the science which analyses e types of man and of his forms of expression.

Geography, History and Anthropology.—In the study of men's e and work on earth there is thus special opportunity for co- eration of human geographer, historian and anthropologist, e first contributing his survey of the factors of place in men's rk, the second elucidating the time-sequences, and the third lping to discriminate types of humanity and of human expres- on involved. It is on the increase of such co-operation rather an on more definite separation of studies that hopes for a great ture advance of knowledge in human affairs depend.

The great man of history is often the man who has a special namic vision of the world about him, who sees whither the inds of multitudes are tending and what the work of con- mporary pioneers will mean in the coming days, and he crystallises out inchoate thoughts. He thus depends very much upon the scene as he finds it. With Francis of Assisi and with Peter the Great, for example, we have the personal factor of vision, energy and initiative extraordinarily developed, yet even here the scene whereon they play their part has its influence upon that part, and the geographer, with his spatial discipline, his study of place, has his share to contribute towards the interpretation even of these mighty personalities and of their work.

If human geography works, especially at the analysis of place relations of mankind, it is deeply concerned both with the comparison and classification of the scenes of human work and with studies of distributions of human phenomena of every kind. For their interpretation it seeks to relate these distributions to one another in order to see how one influences another in the present, and how one in the present has been influenced by another from the past. The collection of data for maps, and the creation of maps which picture the data collected in the most useful way for study of their mutual relations is thus one of the tasks of the human geographer, a task as yet only begun (*see* FOLKLORE).

Culture Distributions.—Among the studies of cultural distributions made in order to get a picture of life in various environments and to suggest interpretations thereof, one may mention especially those of Clark Wissler in North America, and refer the reader to, *inter alia*, his study of *Man and Culture* (1923).

The discussions which followed, for example, the publication of Jovan Cvijic's *La Péninsule Balkanique* (1918) with its studies of cultural distributions show how much need there is for co-operation between students of types, be it of houses or other forms of human expression, and students whose aim is that of the human geographer, namely, the statement of the setting of the stage of human action.

The human geographer utilises, with understanding, the results of his colleagues' work, but concentrates on his own task, his study is the study of places, but in the idea of place are included the features of the place which are due to man's work. He needs that understanding of his colleagues' work, perhaps most of all as a protection for himself against the ascription to influences exerted by the place under discussion of features which may be imported or which may have arisen through other types of sociological influence such as those elaborated by Rivers (*v. inf.*). At the present stage of development, there is scope both for the human geographer, who will concentrate on the picturing of the scene and for the worker in the border zone, who may try both to make the morphological analysis of the facts discussed and to picture the setting of the stage as far as he can.

The anthropological student with his morphological discipline distinguishes types of men, of material objects or of customs or forms of expression in language, and he then seeks their relations with one another and is thereupon impelled to map their distribution in space. In this way, for example, he is led to see a great awakening of life near the western shores of Europe at or just before the dawn of the metal age. He sees the germ of that life developing in the west of the Iberian peninsula, according to some from local, according to others from imported, seeds. He follows the new life to the Garonne estuary, the south and west coasts of Brittany, Ireland and even farther. To make his story live he needs the help of the human geographical point of view accustomed to picture man's relation with environments. The study of copper objects and their successors in bronze must be far more than merely a classification of types.

Human geography can help archaeology (*see* ARCHAEOLOGY) to see the setting of the life of the bronze age. And on the other hand, the human geographer, who is trying to see the modern relations between man and environment in what we may call the Celtic fringe of Europe will miss a great deal unless he appreciates the early days of metal and has some notion of the inheritances those days have left to our own. With this equipment the human geographer is enabled to avoid the gross error of seeking to state the relations of particular men to their particular environment solely in terms of relations observable at present, as well as the other gross error of stating that such relations have come into existence on the spot at which they may now occur

Culture Spreads and Contacts.—Few thinkers have done more in our day than the late W. H. R. Rivers; to show how spreads of culture have altered men's relations to their environments. He worked just outside the sociological frontier of geography and emphasised not only the apparent naturalisation of imported elements of culture, a naturalisation sometimes so marked that *a priori* arguments could easily be constructed to show that these elements of culture must be native, but he has also shown that there is much more in the matter. Importation of elements of culture has often led and still often leads to the weakening of local custom, that is to the removal or abrogation of ancient habits. He has shown that, in some cases, the weakening affects so much that the whole life of the people concerned is dislocated beyond repair and they die out (*see* ANTHROPOLOGY, APPLIED). Sometimes the weakening of old custom due to new contacts has avoided this catastrophe, but has been sufficient to set free a large amount of human initiative and effort. In such cases, new features have appeared that are the result of the play of this liberated initiative, but quite probably have no close relationship to the imported elements of culture. These last acted as the ferment; their direct part in the ultimate result may be small enough.

Especially following Rivers' work and that of the "Kulturhistorische" School in Germany, the study in cultural distributions has had its importance increasingly recognised. We see far more fully than heretofore some of the founts of human initiative, of human influence over environment. We appreciate in a deeper way the fact that men may knit widely differing relations with one and the same region, for we see how much will depend, for example, on the dominance of ancient custom in one case and the importation of cultural elements and associated liberation of initiative, or it may be its destruction, in another. The contrasts between native Patagonian huntsmen and Welsh agricultural immigrants at Chubut illustrate these points.

We see also the wide bearings of the principle illustrated, for example, by the commonplace fact that railways began by linking together places already in existence and then went on not only to modify them and their activities, but also to create new centres, in England new groups of factories, new suburbs, new watering places, in Canada new capital cities, new agricultural lands and the like.

Synthetic Regional Studies.—One of the most appropriate tasks of the human geographer is the study of a particular region, as the setting of human life, and multifarious have been the recent efforts in this direction. Vidal de la Blache wrote his classic *Tableau de la Géographie de la France* (1903) and his followers have written monographs on several of the "pays" or natural units of human life in that country. The monographs vary greatly in value, but on the whole avoid fairly well the errors in the argument of physical determinism. There cannot be said to be a physical predestination of the special developments of human activity in a particular region, the efforts of man, the contacts of autochthones and immigrants and their consequences, all need to be brought into the story. A distinguishing feature of the monographs of this school is the intimacy of the writers with the district about which each writes; that intimacy and attachment have been emphasised by Herbertson and by Younghusband as valuable aids in serious regional study. In several of the monographs in question, on the other hand, there is a lack of maps of cultural distributions especially as regards distributions giving clues to the local beginnings of civilisation; historic documents, however, are widely utilised. J. F. Baddeley's *Russia, Mongolia and China* (1919) and Sir M. A. Stein's *Serindia* (1921) are monumental works on their respective regions which have appeared recently, while Hilton Simpson has made studies of the people of the Aures massif. New works on regional planning for Dublin, Deeside, Doncaster and East Kent are valuable examples of applications of the regional study of human geography.

Scope of Human Geography.—In this province of study of a region and in that of study of cultural, including commercial distributions, the work of the human geographer is well recognised even if he be held to need for this work some systema
knowledge of allied sciences that his work must necessar
touch. The subject of general human geography is, on the oth
hand, still at such an early stage of development that its conte
and scheme are still subject to argument.

Huntington.—Ellsworth Huntington's attempt to give
scheme avoids a claim to be more than a sketch to help you
students to form pictures of the world about them. He treats
men in relation to location, land forms, bodies of water, soil a
minerals, climate, vegetation, animals and other men. F
him the subject is a mass of problems of the relations betwe
environment and human activity. In the course of the work,
touches upon the very deep problem of the relation of man
climate, of his varying energy and initiative in different enviro
ments and he thus introduces study of man along with study
place, with this justification, namely, that such study of man
essential if there is to be a reasonable picture of men in the
various environments.

Schrader.—F. Schrader, towards the end of his life, sketch
a characteristic policy for the development of human geograp
in the 20th century, suggesting that with the modern develo
ment of world-wide connections there was an immensely i
creased practical need for increase of our knowledge and c
sense of the natural laws which rule material and spiritual e
changes of activity between man and the world. Geddes h
long emphasised the need for correlated studies of place, wo
and folk, but without detaching from this wide general task t
special part which the geographer should undertake, unless it
that of place.

Brunhes.—Brunhes has made an attempt to be more sy
tematic and has suggested human geography as the study of a
those facts of the surface of the earth in which human activ
plays a part. He tries to work out first the facts of such occu
tion of the soil as is not directly productive, and treats especial
houses and roads; then he takes up man's work with vegeta
and animal material for productive purposes; next he takes u
man's destructive influence on plants, animals and inanima
materials. Subsequently, after giving analyses of the social l
of a number of natural units of humanity, he proceeds to stu
the bearings of his earlier pages on growth of human society a
its organisation. The debt of this writer to the thought of t
sociological school of Le Play seems to be considerable.

De la Blache.—Vidal de la Blache left at his death notes f
a large work and these have been arranged for publicati
Starting as do both Schrader and Brunhes with the idea of t
world's effective unity, he makes the study of the distribution
population the first concern of human geographers, who m
try to follow its forms of nucleation and its types of scatteri
its migrations and oscillations. Following this, he considers
regional succession the great agglomerations of human popul
tion. In the second place, he includes study of the forms
civilisation to be pursued, especially regionally, but apparent
to be discussed under subjects such as materials, food, co
structions, sites, habitations and so on. In the third plac
he proceeds to the study of the circulation of men the world ove
roads, railways, sea-transport and so on. It was evidently his i
tention to proceed to survey the evolution of races and the di
persion of cultures, and he sketched maps of the distribution r
spectively of animal and of vegetable products used by man an
of constructions which may be supposed to be autochthonous i
different regions of the world.

Commercial and Political Geography.—G. G. Chisholm's ency
clopaedic work, *Commercial Geography* (1889–) may be looked up
as a type of study of a special subdivision of human geograph
which has a peculiar importance for practical life. Several oth
recent works have discussed commercial or economic geograph
with a considerable measure of success.

A few words on political geography may be added. Ratzel
here one of the chief pioneers and his followers in most countri
make the state the unit of treatment, describing and sometim
seeking, to interpret the physical, demographic and econom
facts of each state. A large body of material for political geo

hy has been published in the British Foreign Office and miralty handbooks designed to assist discussion of the treaties recent years. This study is in a sense an applied development general human geography; in another sense it is an alternative dy. Human geography in the stricter sense could not at all nerally accept state frontiers as natural boundaries for divisions its discussions and might well seek, as in some recent studies frontiers, the geographical interpretation of those boundaries ich are in essence human facts.

Conclusion.—The contrasts between Huntington, Brunhes d Vidal de la Blache are evident. In Huntington's work we d the emphasis on man; in that of Brunhes the main emphasis on work; in Vidal de la Blache, the repeated efforts towards ial consideration of regions gives emphasis to place. But all that studies of forms of civilisation occurring in various en-ronments, *i.e.*, that studies on a regional basis are a funda-ntal task; and all bring out the impossibility of the attempt to imit at all strictly mutually exclusive spheres for what may called human geography and anthropology. It is possible at esent only to urge that, in the latter, the main object of study man, his various physical, social and other forms, *i.e.*, imarily morphological.

In human geography, on the other hand, the main object of dy is place relations of men of all kinds, and of any or all their forms of expression the world over. The place relations of e present day are not the only legitimate objects of study. e need the study of these place relations in the past as well if are to have an eye to the future, but it is the present that ves us the truest starting point, for it is here that we may ob-rve most directly how man influences and is influenced by en-ronment. From a study of the present, also, as from nothing se, we may be led to say that man and his surroundings are anging together, and that we cannot set man and environment opposition to one another, save for convenience of discussion, d with the full consciousness that as we do this we deliberately crifice something of the concrete reality. We may accept these awbacks for the sake of reaching generalisations of a manage-le kind, but we must recognise the incompleteness that is a cessary consequence.

There is reason to hope that, on the one hand, regional studies ll progress and that on the other hand studies of distribution of en and of their forms of expression, present and past, will be epened. The first will need intimate acquaintance, loving miliarity, to use Herbertson's phrase, as its starting point, d, however much it may concentrate on the present, it will need consider the past at every turn; it may well need also to bring to its purview some results of study of the differences between an and man; it must remember that the environment presents man opportunities and difficulties, possibilities rather than mpelling influences. The second will need increase of emphasis the study of the places involved and the possibilities they offer deny; that is to say, the student of place will be called upon play an increasing part here, but it remains obvious that the udent of the morphology of the forms of expression studied is ually important, and this is a field especially for a combined fort of students of place, time and type in relation to human ings and their forms of expression, both material and spiritual.

HUMPERDINCK, ENGELBERT (1854–1921), German musician (*see* 13.891), died at Neu Strelitz Sept. 27 1921. His last opera, *Die Marketenderin*, was played at Cologne in 1914.

HUNEKER, JAMES GIBBONS (1860–1921), American musical critic, was born at Philadelphia Jan. 31 1860. He graduated at Roth's Military Academy, Philadelphia, and was a law student for a time, subsequently studying the piano in Philadelphia, Paris and New York. He was teacher of the piano at the National Conservatory, New York City, 1886–98, becoming musical and dramatic critic for the New York *Recorder* and *The Morning Advertiser*. From 1900 to 1912 he was musical and dramatic critic for the New York *Sun*. In 1912 he joined the New York *Times*, but returned to *The Sun* in 1919. He died in Brooklyn, N. Y., Feb. 9 1921. His writings on music, literature and art are notable for their style and popular appeal. His published works include *Chopin: the Man and his Music* (1900); *Overtones: Music and Literature* (1904); *Franz Liszt: a Study* (1911); *Ivory, Apes and Peacocks* (1915). He also supplied the text for Josefy's edition of Chopin's works.

HUNGARIAN LITERATURE (*see* 13.924).—Hungarian literature at the beginning of the 20th century was on the brink of a revolution. The intellectual life of the country was undergoing a crisis. After 1,000 years of a history sometimes glorious, but more often tragic, Hungary was faced by new difficulties which threatened her very life: the social question, the defence of her civilisation and her language against the Slav and Teutonic races, and the antagonism between the essentially rural nature of the Hungarian people and the Americanism and cosmopolitanism of the capital, Budapest.

Writers were divided into two camps: the traditionalists and the moderns. This division still persists. The older generation, inspired by Hungarian nationalism, had joined in the celebration of the country's 1,000th anniversary in 1896 and had accepted modern civilisation but remained firmly opposed to cosmopolitanism and radicalism. They still longed for the Hungarian steppes and the old folk songs. From this generation originated what is known as the Turanian movement, which draws its inspiration and its themes from the East and endeavours to arouse in the Hungarian people the consciousness of their non-European origin. The numbers of this older generation diminish year by year. The patriotic and classical poets, Joseph Lévay (1825–1918) and Alexander Endrödi (1850–1920), followers of Jean Arany, towards the end of their lives burst again into song. In 1910 Hungary lost the novelist Koloman Mikszáth, the most notable successor of Jókai, the immortal painter of the Slovak peasant and the aristocracy of Northern Hungary. Among contemporary writers of this school are the poets Jules Vargha and André Kozma, the novelist Ferencz Herczeg and the critic and essayist Eugene Rákosi, their organ being the review *Budapest. Szemle*, edited by Géza Voinovich.

In opposition to the older generation were the moderns, who hailed the advent of capitalism and industrialism in place of the old provincial spirit. These intellectual radicals wished to eliminate from literature all national characteristics, and to promote the cause of realism with its materialistic philosophy. They turned their faces towards the West, not the chauvinistic West, but the home of cosmopolitanism and anti-nationalism. The moderns gathered their forces in the early years of the 20th century, using as their rallying point a review with the symbolic title *Nyugat*, edited by Ignotus. Round it gathered the young poets of the symbolist and romantic school.

Chief among these men was André Ady, an original Magyar genius, whose primitive and prophetic gifts place him in the first rank of Hungarian poets. Influenced as he was by French symbolism as well as by the works of Zola, he drew inspiration also from the days before the school of Arany, from the melancholy, sometimes crudely expressed, Protestant hymns of the 16th century, from the songs of the rebels against the Austrians, from the archaic and primitive beauties of the Hungarian Bible. His robust language and brilliant vision illumine the depths of the soul. He tilts against conventional morality and describes love with all the voluptuousness of the realist: a trait which is, in fact, common to all the moderns. He is distinguished by a certain aristocracy of mind, as, for instance, in his attitude towards the Nietzschean cult of the Ego, but in his general outlook, and in his hedonistic glorification of blood and treasure, and above all, in his sympathy for the poor and despised, he inclines towards Socialism.

Compared with him, modern lyrical poets such as Michael Babits, Jules Juhász, Désiré Kosztolányi, Árpád Tóth, Gabriel Oláh, Ernö Szép have confined themselves to pure aestheticism, seeking to express the emotions of a cultivated, almost neurasthenic, minority. The realistic novelists found a successor in Sigismond Móricz, whose preoccupation with brutish peasants and corrupt petty tradesmen reflect his political tendencies. His work is the antithesis of that of idealistic novelists such as Géza Gárdonyi (d. 1923) and Cécile Tormay.

When the World War broke out, these two camps, the traditionalists and the moderns, were still divided by a great gulf. Cosmopolitan literature was silent for a time. The poets of tradition hailed the conflict with acclamation. One poet, a soldier, Géza Gyóni, in a language learnt from the moderns, turning his back on *l'art pour l'art*, succeeded in expressing the horrors and pathos of the War. The moderns were not long in making themselves heard, but, as might have been expected, their pacifist leanings were only accentuated by what had happened. Far from joining in the martial chorus which then predominated, their symbolist and decadent verse reflected the trouble in their souls, whilst glorifying man and life.

The final disaster, and the revolution of Oct. 1918 unmasked the political connections of *Nyugat;* its contributors joined hands with the rabble. In the intoxication of the first success the moderns threw off the mask. Their review declared itself to be definitely on the side of the revolution and of Count Karolyi. They looked forward to the end of the old feudal agricultural Hungary, the Hungary of officialdom, of the nobility and of the nationalist writers grouped around both.

During its four months' reign Bolshevism kept literature under strict control. Newspapers were suppressed and the right of publication withdrawn. A single publisher held all the world of thought in fee: the State printed nothing but propagandist papers and pamphlets. The socialised theatres were forced to produce plays in celebration of the revolution. Futurist and expressionist writers alone were protected and subsidised by the "literary directory." This upheaval brought no good to literature. Expressionism pushed to extremes led nowhere.

After the fall of communism, literature set itself to assist in the task of national regeneration. With no definite theories of art or literary programme it expressed the grief of the divided country and its longing for the lost provinces. Although historic Hungary was divided into five parts, Magyar literature kept its unity. In political Hungary the novel took the place of the lyrical poetry of the pre-War period. Désiré Szabó, in his loftily conceived work, describes the great cataclysm of the World War and the determined defence made by the Hungarians, in both the material and moral spheres, against the foreign invader.

Hungarian literature from this time onward endeavoured to break the bonds of torpid decadence and of anti-national radicalism, and to place before a people, struggling in the shadows of adversity, a new conception of the world which should be healthy, energetic and modern, thus again proving that Hungarian literature has always been something more than a mere exercise in aesthetics. Modern drama is striving to create new and lasting values, both poetic and philosophical. Romanticis has reappeared, and talented dramatists such as Feren Herczeg, Ferencz Molnár, Louis Biró and Melchior Lengy have attained to well-deserved success in the theatres of Europ and even in those of America. Realism and purely theatrical effec have, for the time, being quite vanished from the Hungarian stag

In discussing Hungarian literature we must not forget th of the lost provinces of Hungary. In Transylvania in particul there has been a remarkable renaissance. The reawakening a feeling for the mother country has also made itself felt in th Northern Carpathians. There, poets such as the Transylvani Végvári often express under pseudonyms the sadness which, Magyars, they cannot but feel.

HUNGARY (MAGYARORSZÁG, *see* 13.894), an independent kin dom of Central Europe. Previous to 1918 Hungary formed pa of the Austro-Hungarian Empire, whose monarch was Apostol King of Hungary. The Lands of the Hungarian Crown had a area of 125,402 sq. m., of which Croatia and Slavonia, whic were in political union with Hungary, occupied 16,420 sq. mile The census of 1910 gave the population of Hungary as 20,886,48 including 10,050,575 Magyars (for racial statistics *see* AUSTRI HUNGARY). The Treaty of Trianon (*see* TRIANON) in 1920 d prived Hungary of all Croatia, Slavonia and Transylvania an much of Hungary proper. Her new frontier runs as follows:—

> Starting from the junction of the Czechoslovak and Austria frontiers near Bratislava, southeast to the mouth of the Ipel rive then along its course to a point 10 km. below Lučenec; hence sout east above Salgotarján, northeast up to a point lying 20 km. sout of Košice, southeast above Sátoraljaújhely to Csap, thence alon the Tisza to the junction of the Rumanian and Czechoslovak fro tiers. After running west of the Satul Mare Oradia-Mare line, turns west, and runs south of Makó to the Yugoslav frontier belo Szeged; hence south of the junction of the Maros and Tisza sout west to a point on the Dráva south of Pécs; hence west and nort west along the Dráva to the mouth of the Mur; along the Mur, th north to Szentgotthard; hence north to Köszeg, then makes a loo to include Sopron, crosses Lake Neusiedler (Fertö), thence north the Czechoslovak frontier.

The area comprised within these frontiers is 35,916 square mile Population (1920), 7,989,143. Of these 7,147,530 were Magyar 551,211 Germans, 141,882 Slovaks, 23,760 Rumanians, 36,858 Croat 17,131 Serbs, 1,500 Ruthenians, 69,271 other races. Some 3,250,00 Magyars were living within the frontiers of Czechoslovakia, Rumania Yugoslavia and Austria (*see* MINORITIES). The Treaty took fro Hungary all her gold, silver, copper, salt and mercury mines; a but one of her iron mines; her largest and best collieries; and 86 % o her forests. The only branch of productive territory of which sh retained over half is viticulture (68 %). The strongest social elemen left to her was her peasant class (4,449,105 persons were engaged i agriculture). There was a very large intellectual class, compose largely of ex-state employees formerly resident in the territory o the present Succession States, the settlement of which formed a grav problem.

I. POLITICAL HISTORY

At the fateful Crown Councils of July 7 and July 19 1914, th only person present who opposed the idea of an attack on Serbi or any measure beyond the formulation of severe but acceptabl demands to Serbia was Count Stephen Tisza, then Hungaria Minister President. Thanks to his influence alone, a passag was entered in the minutes of the second council as follows:—

> The Common Cabinet Council, on the motion of the Ministe President of Hungary, decided that immediately after the com mencement of hostilities the foreign Powers should be notified o the fact that the monarchy was not waging a war of conquest, an that it was not the object of the monarchy to annex the Kingdom o Serbia.

Tisza, however, made no statement on his conduct until Oct 17 1918 when he mentioned it in the Lower Chamber of th

ngarian Parliament, enumerating the documents in which it s recorded (*see* Austria-Hungary).

The Collapse of the Monarchy.—The causes of the catastrophe 1918 were partly internal, partly international. After the th of Francis Joseph I. on Nov. 21 1916 the rule of the Dual narchy gradually lost its character of stability. Austria was ady weak; and the dismissal of Tisza (May 22 1917) made ngary, too, helpless. However, as the armies of the monarchy l occupied considerable enemy territories, few people thought he possibility of its sudden collapse. The protracted war had ome extremely and increasingly unpopular. The general ire for peace and the weak and irresolute policy of the Gov- ment contributed to encourage the defeatist agitation. The ice propaganda was furthered by the publication on Jan. 8 8 of President Wilson's Fourteen Points, which were accepted h implicit faith by the Hungarian people, who have always wn a sincere enthusiasm for the great ideas of mankind. The urn home of large numbers of soldiers released from Russian tivity after the Treaty of Brest-Litovsk (Mar. 3 1918) fur- red the growth of communistic and anti-militarist ideas, which re enormously strengthened by the privations and suffering ised by the blockade. Only on the capitulation of Bulgaria pt. 29 1918) did the situation become quite clear. The rev- tionary movement now ceased to be a merely sporadic phe- menon; foretokens of the coming upheaval became everyday urrences.

The first signal of the process of upheaval was a demonstration students on Oct. 25, the crowd being, however, dispersed by police. The same day the so-called National Council was med, with Károlyi as its president, together with a soldiers' uncil and a students' council. Lieut.-Gen. Baron Lukachich, o had been appointed military governor of Budapest, sug- sted that Károlyi and the members of the National Council be ested; but the suggestion was not approved by the Govern- nt just resigned. Two days later the National Council issued proclamation with the title "Amnesty and land for the sol- rs," which foreshadowed the coming of Bolshevism. Now nts succeeded one another with bewildering rapidity. Two npanies ordered to the front mutinied and, joining the groups of demonstrators during the evening of Oct. 30, attacked and seized the headquarters of the commander of the garrison, the telephone exchange and the general post office. Gen. Lukachich telephoned to Vienna for instructions, but the King refused to consent to the employment of the armed forces at the Baron's disposal. By the morning of Oct. 31 the town was completely in the hands of the revolutionaries; Károlyi was appointed Prime Minister. His Cabinet included principally persons without seats in Parliament, Social Democrats and Radicals; of the parliamentary parties only the Independence party (Kossuth party) was represented in the Government, several of the ministers chosen by Károlyi belonging to it.

The same afternoon Count Stephen Tisza was murdered, probably by emissaries of the soldiers' council. His friends had repeatedly warned him; but he had remained in Budapest in a final effort to unite all the elements of order against the rabble. Tisza knew how critical was the situation and he knew that he was threatened by death. The followers of Károlyi ordained as a national holiday the very day on which they laid Tisza low. On the other hand, it appeared to Károlyi's opponents that with the disappearance of a formidableantagonist he lost his personal initiative and became little more than a puppet in the hands of Jászi, the Radical party and the Socialists.

The first measure taken by the new Government was to demobilise and scatter in all directions the soldiers pouring back from the front. The war minister—Béla Linder—declared that he "did not wish to see soldiers"; and Hungary was thus disarmed and rendered powerless both to stem the internal anarchy of the country and to resist occupation from without. The first result was universal looting and robbery; then followed the invasion of the Czechs, Rumanians and Yugoslavs. The Czechs were able to occupy the almost impregnable fortress of Komárom on the Danube without striking a blow, for the troops of occupation met not the slightest resistance anywhere. In vain did the inhabitants everywhere protest against the occupation; the Government was both unable and unwilling to do anything to lend weight to their protests.

On Nov. 1 the Austro-Hungarian delegates had met the Italian generals Diaz and Badoglio to conclude an armistice. Point 3 of the conditions enunciated was that the Austro-Hungarian troops were to evacuate all enemy territory occupied in the War; a line of demarcation was drawn in the southwest; elsewhere it was to consist of the former political frontier. Gen. Weber, who was authorised by the Hungarian Govt. to negotiate for Hungary, accepted these conditions in the name of Hungary. Károlyi and a delegation of his Government, however, believing that he could get better terms from the Entente, called on Gen. Franchet d'Esperey in Belgrade, who concluded a separate "military convention" with them on Nov. 13. This fixed a line of demarcation well within the old political frontier (Bistrita-Nagy-Szamos-Marosfalli-Subotica-Baja-Pécs), the line of the Drava. Hungarian troops were to withdraw behind this line, but Hungarian police, gendarmerie and civilian control would continue to function. The Allies were entitled to occupy any towns or other points of strategic importance but would not interfere with the internal administration. Hungarian troops were to remain to secure the line of demarcation.

In fact, however, the occupying troops, backed by the inter-Allied missions in Budapest, denied Hungary any sovereign rights in the territory outside the line of demarcation; assumed the civilian administration, removing the Hungarian officials; disarmed the gendarmerie and police; set up an economic boundary; interrupted communications; forced inhabitants to take an oath of allegiance to themselves, and even pressed them into military service. It thus became abundantly clear that Károlyi could not obtain better terms from the Entente, and his popularity at once began to wane.

Proclamation of the Republic.—On Nov. 13 Charles IV. issued the Eckartsau manifesto, declaring that he "resigned all share in the conduct of state affairs and was prepared in advance to accept any decision to be taken by Government respecting the future form of government of Hungary." The Károlyi Govt., without consulting Parliament, at a mass meeting in Budapest proclaimed Hungary a republic (Nov. 16). Under pressure from the Government the House of Deputies proclaimed its dissolution; the only protest against this arbitrary measure was that contained in the declaration read by Baron Wlassich, president of the Upper House (House of Magnates), who at the same time announced that the Upper House had adjourned its sittings for an indefinite period. The counter-revolution received legal sanction from the illegality of the proclamation of the republic. William Böhm, who was Minister of War under Károlyi, writes that there were 50 cases of riot, most of them involving fatal consequences, while 14 different military formations were raised to deal with the counter-revolutionary movement. Complete anarchy prevailed in the administration. The Government admitted that the "national councils" of the provincial towns were daily guilty of grave abuses but alleged that it was powerless to prevent them. Jászi admitted that they had made a revolution without having any men to do the everyday work.

Not only did they fail to do anything to save the territorial integrity of Hungary, they were even incapable of achieving any radical reform. They were not satisfied with a mere republic, "it had to be a people's republic." The plebiscite promised by the National Council was never held by the Károlyi Govt., for their few months of power yet sufficed to make them not dare to appeal to that national public opinion in the name of which they consistently spoke and acted. Károlyi was proclaimed President of the Republic on Jan. 11 1919 and on Jan. 19 formed a Cabinet under the presidency of Denis Berinkei, then Minister of Justice. It had no proper support either among the bourgeoisie or among the socialists; yet it created a whole series of laws and ordinances. Never had there been so rapid and so general a promotion of public employees, for the older employees were in general regarded as unreliable. Following the precedent of the United States Károlyi as "provisional President of the Republic" took part in the Cabinet Councils and frequently spoke at these meetings.

There were two questions of first-rate importance: universal suffrage and land reform. A protracted discussion preceded the drafting of an ultra-modern suffrage bill (drafted and pass *intra muros*, without reference to Parliament, which did exist). But the bourgeois parties were beginning to recover fr their apathy. The suppression of individual liberty, the inti dation of the bourgeois press, and the policy of internment last began to change their initial lethargy into a determinati to rally their forces; and it was already clear that a very stro Catholic party would contest the elections; consequently, G ernment continually postponed the elections and finally mano vred them off altogether. Nor did Government materialise promised scheme of land reform.

The Allied Powers meanwhile bombarded Hungary w ukases. Col. Vyx, their representative in Budapest, permitt the Czechs, Rumanians and Yugoslavs to pass at will beyo the line of demarcation. The Government still maintained t a "peace by agreement" would follow; shortly afterwar however, the radicals and Jászi resigned from the Cabinet, wh was now clearly lacking the support of public opinion.

The Soviet Republic.—The agents of the Russian Soviet long since begun their work in Budapest. Béla Kun, who been sent home from Russia to organise the Hungarian Sovi had been in Budapest with some associates since Nov. 19. Th men had money; they were daring and active and rapidly gai a following, not only in the organised proletariat but also amo the socialists and the "intellectuals." They arranged dem strations among the soldiers returned from the front; they manded the payment to these men of immediate relief. C tinuously increasing their demands, they gained larger and lar masses to the cause of revolution. On Feb. 20 1919 a mass me ing of unemployed yielded entirely to Communistic influen To intimidate the Socialists they attacked the offices of th organ the *Népszava*, killing seven policemen and wounding After protracted discussion the Government imprisoned B Kun and his followers. The funeral of the murdered policem was a gigantic demonstration of the people against Bolshevi and in favour of Socialism. It seemed as if Bolshevism had b finally overthrown.

On the morning of March 20, Col. Vyx handed Károlyi a n establishing a new neutral zone between the Hungarian a Rumanian troops. This area comprised some 2,000 sq. m. predominantly Magyar territory. Vyx afterwards stated th the zone was to be purely neutral, remaining under Hungari administration. Károlyi contended that Vyx had stated th Rumanian troops would occupy this area. At a Cabinet Cou the same evening Károlyi resigned as President of the Republ and a resolution was passed that, as the Coalition Govt. saw prospect of solving the political crisis or of ensuring producti the Social Democrats must take over the government. T Socialists, however, were too weak unless supported by the Co munists. On March 21, at noon, the Socialists decided to co to terms with the Communists, undoubtedly at Károlyi's p sonal instance. It is true that the difficulties were numerou but Károlyi and Jászi had been unequal to them. The ho aroused by their promises had not been fulfilled and their ph of the revolution had ended in chaos.

The agreement between the Socialists and Béla Kun was ma in the prison. The Communists dictated and the Sociali accepted everything. The whole Social Democratic party unit *en bloc* with the Communists. Pending the decision of the Th International the new party was styled "the Socialist party Hungary"; it was to take over the power at once in the na of the proletariat; the dictatorship was to be wielded by Labourers, Peasants and Soldiers' Council; urgent steps we to be taken to organise a "class army" and completely disa the bourgeoisie; a reign of terror was to be proclaimed to ens the rule of the proletariat; a close military and spiritual allian was to be made with the Russian Soviet.

By the evening (March 21 1919) the streets were in the han of armed Communists; at 6 P.M. the public prosecutor visit the prisons to release the prisoners. At the head of the govern council was placed Alexander Garbai, a bricklayer. His ass

s in the council of people's commissaries were Kun, Joseph
iny, president of the Soldiers' Council and Sigismund Kunfi,
ondary school teacher who had been a member of Károlyi's
inet. The people's commissaries and practically all the lead-
persons were Jews, a fact which explains the anti-Jewish
ng which later prevailed in Hungary. Károlyi's revolution
been in part an imitation of that of Kerensky; Hungarian
munism took Lenin as its model, though Lenin is said to
warned Béla Kun to take into due account the fact that
litions in Hungary were essentially different from those pre-
ng in Russia. As the majority of the people's commissaries
been prisoners of war in Russia, they often spoke Russian
eir meetings. They ordained the "communisation" of the
, of industrial establishments, of houses and factories, of all
rtakings and shops. Jewels of a value in excess of 2,000
ns were to be surrendered; the deposits entrusted to the
s (both savings and current account deposits) were seized
communised.

rom the outset there were two distinct currents of opinion
e Government: a moderate and an extremist. At first the
list influence predominated and the action of the communists
more of a chicanery than a persecution. On April 4 Gen.
ts arrived in Budapest to negotiate with Kun's Government
ehalf of the Allies. He offered to recognise the disputed
not as a political frontier, but as a line of demarcation only,
e bordered by a neutral zone. Kun insisted that the Bol-
ik system must be introduced in the neutral zone. Smuts
e off negotiations. On April 16 the Rumanians advanced
g the line of demarcation up to the Tisza (Theiss). As their
tion was now menaced by the danger of a counter-revolu-
, the Bolsheviks resorted to undisguised persecution. In
apest alone they took 481 "hostages," and several thousands
e throughout the country. The Red Army was organised,
arily to ensure the maintenance of the dictatorship. Later,
n they saw that the national feeling and popular exaspera-
was growing even more formidable, and that terror, intern-
t, torture and assassination could no longer keep passions
heck, the Bolsheviks commenced an offensive campaign,
ated the Czechs, occupied Košice (Kaschau) and advanced
o the Polish frontier at Bardiov (Bartfa). But, after receiv-
Clemenceau's note of protest dated June 8, they withdrew
r troops, and on June 13 were fixed the definitive frontiers
h condemned Hungary to dismemberment and helplessness.
his catastrophe instilled fresh courage into the counter-
lutionaries. On June 24 the cadets and officers of the mili-
academy, assisted by the Danube monitors, some of which
stationed in the winter harbour at Ó-Buda, assumed the
nsive. On this occasion the Red Army suppressed the coun-
revolution; but communism never recovered from the shock,
no one believed it could long maintain its position. As there
been counter-revolutionary movements in the provinces too,
Red Terror made its appearance. Indisputable official data
e recorded the murder by the terrorists of 585 persons, includ-
Louis de Navay, a former Speaker of the House of Deputies
one of the most distinguished Hungarians of his day; the
ber of persons of obscure origin who may also have fallen
ims to Szamuely's thirst for blood is unknown. Throughout
Commune Budapest suffered from a disastrous shortage of
visions, due not only to the blockade, but still more to the
sive resistance of the peasantry.

he Communists employed their money for propaganda pur-
es, particularly in Austria. Budapest lived mainly on pearl
ley and vegetable marrow; anyone desirous of obtaining bet-
food was compelled to go to the provinces and offer clothes
etroleum in exchange for meat or bread. Unrest and dis-
tent were general; even the trade unions were beginning to
in secret against the Soviet régime. There was a breach
ween Béla Kun and Haubrich, commander of Budapest and
ler of the iron and metal workers. As an open rupture seemed
inent, it was proposed that the garrison of Budapest should
laced under Szamuely, the most bloodthirsty of all the Jack
ches in the service of the dictatorship. Luckily, the Italian colonel, Romanelli—who had already collaborated with the American mission to save the lives of hostages and prisoners—prevented this baleful scheme.

On July 20 Béla Kun began hostilities against the Rumanians in the hope that his propaganda had demoralised their troops. The Rumanians defeated him easily and advanced on Budapest; whereupon the outbreak of internal discontent overthrew the Bolshevik régime. The Soviet Govt. resigned on Aug. 1. Most of its leaders fled to Austria. A Socialist Govt. under Peidl was formed, which guaranteed the sanctity of private property. On Aug. 4 the Rumanians entered Budapest. Two days later the organised bourgeoisie overthrew the Socialist Govt. in which they felt no confidence since its recent connection with the communists, and a Government was formed under the presidency of Stephen Friedrich.

The Counter-Revolution.—The restoration of a stable régime in Hungary proved extremely difficult. In May 1919 a counter-revolutionary Government had been formed at Arad—then already occupied by the Rumanians—under the presidency of Count Gyula (Julius) Károlyi, which endeavoured to act as the representative—as against the reign of terror of the Commune—of the ideas of bourgeois order, of the historical integrity of Hungary and of the principle of legal continuity. At first this was little more than a demonstration, since it lacked real power. After a few days the Rumanians sent this Government under military escort, first to the state estate at Mezöhegyes and then to Szeged which, was at that date occupied by French troops.

The Szeged Govt. began to organise a counter-revolutionary army out of a nucleus of volunteers who had distinguished themselves during the War and had fled to Szeged to escape the Bolshevik Terror. Its sphere of authority hardly extended beyond the inner confines of the town, but the authorities in occupation made many difficulties for both the military organisation and the civil administration. A certain success was achieved by the Szeged Govt. through its representatives in Vienna, under the guidance of Count Bethlen. This "detachment" kept in touch with foreign countries and informed public opinion of the West of the misdeeds of the Hungarian Soviet régime.

After the fall of the Commune the Szeged Govt. suspended its activity, and those detachments of the Hungarian national army which had been formed at and near Szeged moved their quarters to Siófok on Lake Balaton. The Government appointed Admiral Nicholas Horthy commander-in-chief of the national army.

In Budapest, meanwhile, the popular Archduke Joseph assumed the government, assisted by Stephen Friedrich as Prime Minister; but the Supreme Council in Paris refused to recognise any Habsburg in a position of authority in Hungary and sent four generals to Budapest to represent the four Principal Allied Powers. The Archduke Joseph was forced to resign. The four generals were fully occupied in thwarting the excesses of the Rumanian troops of occupation in Budapest, who plundered and destroyed property wholesale. According to the report dispatched by Col. Loree to Paris, the value of the goods requisitioned by the Rumanians exceeded 90,000,000 gold crowns (about £3,750,000). The Rumanians also aggravated the difficulty of the Friedrich Government. The Entente then deputed Sir George Clerk to negotiate as plenipotentiary delegate of the Supreme Council and pave the way for the constitution of a Coalition Government to include all the political parties with which the Entente could properly conclude peace. On Nov. 22 Friedrich resigned, and a Government, including representatives of all parties, was formed, Huszár being Minister President.

On Nov. 14 the Rumanians withdrew to the line of the Tisza (Theiss), and Horthy entered Budapest at the head of the small national army, amid the enthusiasm of his many adherents. General elections were held in Jan. 1920 on the basis of a suffrage (secret ballot) of a practically universal character. They gave a considerable majority for the parties of the Right which formed the Government alone. This was a natural reaction after nearly a year of excesses committed by the extreme Left. Those regrettable acts of violence known and described abroad as the "atrocities of the White Terror" sprang from a similar revulsion. It is a fact that, immediately after the fall of the Commune, certain "detachments" were formed in various parts of the country, which arbitrarily executed Communists; however, such atrocities were nothing like as numerous as those committed by the Soviet régime. The victims of the period following the overthrow of Communist Dictatorship number, according to data compiled by the Hungarian Ministry of Justice:—

Victims of the White Terror	279
Killed while attempting armed resistance	9
Killed in flight	19
Total	307

By Act I. of 1920 the new National Assembly restored and once more put into force all that part of the ancient constitution which had been destroyed or eliminated by the revolutions. Act XLV. of 1921 proclaimed Hungary to be a monarchy (kingdom), the decision relative to the exercise of the kingly power being postponed to a later period. On March 1 1920 the National Assembly elected Horthy to the office of Regent unanimously and by acclamation. At the same time a law was passed defining the constitutional power of the Regent.

The Treaty of Trianon.—The Hungarian peace delegation, headed by Count Albert Apponyi, Count Paul Teleki and Count Bethlen, arrived in Paris Jan. 7 1920. On Jan. 15 it received the conditions of peace framed by the Allied Powers, to which it replied on Feb. 27 in the form of a long memorandum, which, together with Count Apponyi's speech made when handing it over to the representatives of the Allied Powers, took the view that the conditions were unjust and must lead to catastrophic results. But the leading members of the Peace Conference would not agree to a plebiscite. The delegation was, however, allowed to put its observations before the Peace Conference itself with better success. Thus, M. Millerand promised, in the name of the Allied Powers, that the boundary commissions should be instructed, where they found the new frontiers involved any economic or ethnical injustice, to appeal to the League of Nations. Unfortunately, the Conference of Ambassadors found that any alteration of the frontiers, however slight, would be equivalent to a breach of the Peace Treaty.

The Treaty of Peace was signed on June 4 1920 in the Trianon by the Hungarian delegates and ratified by the Hungarian Parliament on Nov. 15. M. Simonyi-Semadam, who had succeeded M. Huszár as Prime Minister in March 1920 with a transition Cabinet, resigned in July 1920. Count Paul Teleki, the new Prime Minister, carried through the first stages of Hungarian consolidation. There were only slight differences among the four Government parties. The orthodox Legitimists and Liberals formed the Opposition. On the monarchist question Legitimists and Free Electionists were found in Government and Opposition parties alike.

King Charles' Attempts at Restoration.—On March 27 1921 King Charles IV., misled by the general depression which followed the signature of the treaty, and ill-advised by his entourage, arrived at Szombathely, whence he motored to Budapest, driving straight to the residence of the Regent, whom he called upon to hand him over the power. Horthy replied that the nation was spiritually unprepared for so sudden a change, which might involve a grave upheaval. The Little Entente might use the restoration as a pretext to annihilate Hungary's independence. King Charles returned to Szombathely. Meanwhile the ministers of the Great Powers, of Yugoslavia and of Czechoslovakia declared that the continued residence of King Charles in Hungary might involve the most serious consequences.

On Oct. 20 of the same year King Charles and Queen Zita left Switzerland by aeroplane, landing at Dénesfa, near Sopron. The gendarme battalion stationed at Sopron joined the King, and its example was followed by other troops. The King appointed a Cabinet, with Stephen Rakovszky as Premier, and on Oct. 22 he started for Budapest, his soldiers following him. Telegraphic and telephonic communication with Budapest had been interrupted. As soon as the Government were informed of what happened, they declared that, in view of the foreign politi situation, the King was not entitled to exercise royal prero tives in Hungary and called upon him to leave the territory the country. The Regent sent a letter to the King explaining him that, if he entered Budapest, this might result in the of Hungary. His Majesty should come alone, unaccompanied soldiers or by his Cabinet, and clear the situation in confere with the legal Government of Hungary and with the minist of the Entente Powers. However, the King continued his j ney, refusing all intervention. On the next morning, Oct. 2 small skirmish took place between the King's troops and th of the Government, at Budaörs, near the capital. The Kin troops retired and dispersed. The royal couple were taken the abbey of Tihany, near Lake Balaton, there to await decision of the Entente Powers. Yugoslavia and Czechoslova had already decreed mobilisation. On Oct. 31 the Conferenc Ambassadors demanded the formal deposition of Charles and the dynasty. On Nov. 3 the Hungarian Govt. introduced a abrogating Charles' sovereign rights, and on Nov. 5 decla that before proceeding to settle the question of the election a future king, they will agree previously with the Great Pow represented on the Conference of Ambassadors, and will not without their consent.[1] On Nov. 1 the King and Queen had Hungary on the British monitor H.M.S. "Glowworm" Funchal on the island of Madeira (*see* CHARLES).

Period of Depression.—In April 1921 Count Bethlen had s ceeded Count Teleki as Premier. The international position Hungary had been seriously shaken by the royal attempts restoration. The tension only abated very gradually and events at Budaörs were doubly unfortunate since they follow closely on the Venice Conference (Oct. 11 and 12 1921) by whi thanks to the intervention of Italy, an agreement had be reached with Austria that a plebiscite should decide the fut of the town and environs of Sopron (Oedenburg). The plebisc went in favour of Hungary (*see* BURGENLAND).

At the end of the Commune the Hungarian crown had still be quoted in Zurich at 20% of its pre-War value. Since then it had clined steadily. The chief cause of the financial catastrophe naturally the historical and political collapse of Hungary, wh had been followed very rapidly by a general economic crisis. F the occupied territories, several hundreds of thousands of pu employees and their families had been pouring into the country, they had to be provided for by the Government. As there was a gr dearth of housing accommodation in Budapest, most of the mis able refugees had to live in railway trucks, indeed, incident monopolising for years a considerable proportion of the rolling st of the State railways, already grievously diminished by Rumani requisitioning. The destitution and misery of the population fearful; everybody everywhere demanded assistance from state, which, despite its meagre revenue, was compelled to assi unless thousands were to die of starvation. The state resorted inflation and the currency soon became worthless. Business st nated. The rate of interest at times reached 40–50% per mon Speculation was rife. No efforts of the successive finance ministe neither the stamping of the currency notes—a measure taken avoid a further inflation—nor the sequestration of 20% of the deposits, 15% of the shares and 17% of the larger estates, co remedy the situation. The rate of exchange in Zurich fell to 0·00 One or two branches of industry—such as the textile industry prospered, since they were protected by high tariffs and labour cheap; but the state and a very large part of the population we faced with utter ruin.

Conditions at home required a strong Government and a work majority in the National Assembly, and such an issue could only secured by new elections. On the expiration of the prescribed pe of two years, in Feb. 1922, the National Assembly was dissolve and the elections held in the spring gave the Government a majority. There was, however, a strong opposition consisting Liberals, Democrats, Kossuthites (independents), 24 Socialists 20 "Neutrals." In order to secure the working capacity of the tional Assembly, the standing orders of 1907 were revised wi beneficial results. In the elections of June 1922 the Bethlen Gover ment secured a great majority and formed the United party of sma holders, bourgeois, industrials and great landed proprietors. Out 242 seats in the national assembly the United party secured 14

Christian National United Party 32. The Social Democrats ured 24 mandates.

Count Bethlen now reconstructed his Cabinet with a pro- mme of “ the complete liquidation of the revolutionary spirit, extension of civil rights and economic reconstruction.” His in object was to ensure consolidation. The tide of extremist sion was on the ebb, and the policy of the golden mean proved st likely to achieve favourable results. The conditions of lic safety were restored. The outrages perpetrated against Elizabeth Ward Club (on April 2 1922) and against the Inn ngrád (somewhat later) were the last attempts to subvert public er. It now became possible to set about realising the two most ent reforms: agrarian reform and financial reconstruction.

Agrarian Reform.—The land reform question is inseparably nected with the name of the late Minister of Agriculture, phen Szabo de Nagyatad. To provide the landless with land evy was raised upon the latifundia. Official figures for the iod Jan. 1921 to Nov. 1925 show that 845,567 cadastral ac. cadastral ac. = 1·422 English ac.) were requisitioned and tted respectively for 168,263 house sites and for the forma- n of “ dwarf ” and small holdings, while in 650 parishes 123,- cadastral ac. were taken over for the formation of small seholds. Proceedings for the compulsory purchase of land the purpose of grants to the landless have been instituted or lications for such institution filed in altogether 3,532 parishes. carry through such proceedings, the national land distribu- n tribunal has dispatched judges to 3,526 parishes, and the unal has exercised its right of pre-emption in 300 cases, ecting altogether an area of 15,816 cadastral acres. Landed perty has been parcelled out in 273 cases, the area involved ng 62,328 cadastral acres.

The Reconstruction Plan.—As a result of the World War and the sequent revolutions, the Hungarian state budget and balance of ments both showed a considerable deficit, while the unsettled arations problem perpetuated grave uneasiness in Hungary which in made foreign capital adopt an attitude of absolute reserve. e Government was convinced that economic reconstruction was of the question unless adequate capital was available to stabilise crown until public finances were again balanced. The Govern- nt could only secure the necessary capital by means of a foreign n, but there were grave obstacles in the way of a negotiation of h a loan, since, for the security of their reparation claims, the ied States had the right to regard those claims as a charge on all assets and revenue of the Hungarian State (“. . . the first charge on all the assets and revenues of Hungary shall be the cost of aration and all other costs arising under the present treaty . . .” t. 180 of the Treaty of Trianon). The loan which the Hungarian vernment desired to take up through the intervention of the gue of Nations could not be negotiated until the reparation com- ssion had, with the consent of all the states claiming reparation, eased the assets and revenues of Hungary from the general charge as stipulated, and until Hungary, as a member of the League of tions (she had been admitted Sept. 18 1922), had submitted a re- est to that effect.

On Oct. 17 1923 the reparation commission agreed in principle to spend the priority of charges on the assets and revenues of Hun- ry and thus to approve of the negotiation of the foreign loan to taken up under the aegis of the League of Nations. The Council the League, at its session in Paris in Dec., was thus able to cuss the flotation of the loan, while the experts sent to Budapest the Council elaborated—in conjunction with the Hungarian vernment—a programme of reconstruction. By request of the uncil the financial committee of the League—on the basis of gotiations carried on in respect of questions of detail with the rties concerned—drafted two protocols (*procès-verbals*), which re accepted by the parties concerned and adopted—*nem. con.*—at meeting of the Council held on Dec. 20.

The first protocol was of political nature. Great Britain, France, aly, Rumania, Yugoslavia and Czechoslovakia engaged to respect territorial integrity, sovereignty and independence of Hungary, t to endeavour to obtain any economic advantages calculated to langer that independence, and to abstain from all action likely to n counter to the spirit of the agreements to be concluded for the rpose of furthering the financial reconstruction of Hungary; ngary engaged to meet her international obligations faithfully d punctually, and similarly to abstain from all action in defiance the agreements to be concluded for the purpose of furthering her ancial reconstruction. The protocol affirms Hungary's full liberty action in respect of all questions affecting her own economic stem and commercial relations, while requiring her not to put into ce in her relations with any other state such special measures as ght be calculated to endanger her independence.

The second protocol contains the detailed conditions relating to the floating of the loan:—

The Hungarian Government shall submit to the League the programme of reforms to be gradually materialised and of economic reconstruction; detailed statements being presented every six months during the period of reconstruction of the minimum revenue expected and the maximum expenditure which the country is able to undertake, and the measures proposed to decrease expenditure and increase revenue; the whole must comprise a scheme which shall provide for the restoration of the balance of the public budget by June 1926. The programme must preclude any recourse being had to any other loan, or to inflation. Hungary engages to endeavour to conclude commercial agreements, in particular with the neighbouring states, for the purpose of eliminating the obstacles impeding trade. The Hungarian Govt. undertakes to secure the approval of the scheme by the National Assembly. It is empowered—within the period required for the restoration of the balance of the budget—to take up a foreign loan of 250,000,000 gold crowns to secure surplus expenditure, the proceeds of such loan to be available only in accordance with the provisions of the protocol. Hungary consents to the League of Nations appointing a commissioner-general to be resident in Budapest, whose duty it shall be to control the execution of the reform programme. The commissioner-general shall submit to the council a monthly report on the results obtained during the working out of the programme. As security for the loan the Hungarian Government mortgages the gross revenue of the customs, the sugar tax and the tobacco régie, the net revenue of the salt régie, and where required such other special sources of revenue (mortgage rights) as that Government shall appoint by agreement with the commissioner-general, save only the revenue of the Hungarian state railways. The Hungarian Govt. engages not to take any such measures as in the opinion of the commissioner-general are calculated to prejudice the value of the charges thus stipulated. This protocol also contains a provision to the effect that the obligations devolving on the Hungarian Govt. shall only be in force in the event of the reparation commission taking a decision to that effect.

At its meeting held on Feb. 21 1924 the reparation commission released the state revenues acting as security for the loan, and agreed to the floating of a loan of 250,000,000 gold crowns. At the same time the reparation commission fixed the payments and deliveries to be made by Hungary in respect of reparation liability within the limits of a fixed schedule amounting to 200,000,000 gold kronen spread over 20 years. These payments and deliveries are graduated from 880 tons of coal or its equivalent in value from Jan. 1 1924 to Dec. 31 1926; then until Dec. 31 1928, annual payments of 5,000,000 gold kronen which increase by degrees until 14,000,000 per annum is reached in 1942 and 1943. This removed the last obstacle to the putting into force of the Geneva protocol which was formally signed at Geneva on March 14 1924. The commissioner-general appointed by the League of Nations, Mr. Jeremiah Smith, an American citizen, took up his duties on May 1 1924.

Connected with the reparation question are the liabilities undertaken by Italy and by the Succession States, viz.: Poland, Rumania, Czechoslovakia and the Serbo-Croat-Slovene State, to pay to the Reparation Commission the value of the state properties (railways, forests, public buildings, etc.) of the former Austro-Hungarian Monarchy situated in the territories ceded to them, and further a contribution to the expenses incurred by the Allies in liberating the people of the said territories. These liabilities, which in the aggregate would amount to a very large total, were to be paid off, with 5% interest, in 30 years from Jan. 1 1926, but no payment has hitherto been made. It should also be mentioned that Italy and the Succession States were, in accordance with a now generally accepted principle of international law, required to take over a share of the pre-War Austrian and Hungarian public debts proportionate to the Austrian and Hungarian territories they respectively acquired.

The reconstruction imposed heavy burdens on the Hungarian people. The state was obliged to exercise the utmost economy in order to balance its budget; it had to dismiss many thousands of public servants—25,000 had been dismisssed up to Dec. 1925—and withdraw the subsidies previously granted to numerous branches of production. All taxes had to be raised to the utmost point possible. Yet the reconstruction proved a decided success, and the balance of the public finances was restored at the very opening of the period appointed for the reconstruction. The League of Nations expressed great satisfaction at the success of the scheme; and both the Council (in September 1925) and the General Assembly, during its 1925 session, conveyed to the Hungarian Govt. and the commissioner-general its sincere appreciation, also expressing its admiration for the generosity and self-sacrifice of the Hungarian taxpayers.[1] During 1924–5 the Hungarian Govt. was actively engaged in an endeavour to settle the questions still pending with other states, and in particular with Hungary's immediate neighbours, and to develop the friendly character of Hungary's international relations.

---

[1] In June 1926 the Council of the League of Nations decided to terminate the control of Hungarian finance on June 30, the reconstruction having proceeded more rapidly than had been expected. Supervision was retained in two respects only—over the revenues assigned as security for the Reconstruction loans, and over the unspent balance of those loans.

A series of agreements were concluded with Austria, Rumania, Yugoslavia and Czechoslovakia, referring to legal questions and a general rapprochement in respect of economic and commercial questions and of financial and credit transactions. Hereby the Hungarian Govt. has shown indubitably that it is desirous to remain true to its own policy, the cardinal principles of which are consolidation and the solution of the fundamental problems of peace. These latter naturally include also the securing of the cultural, economic and political liberty of the Hungarian minorities living in the territories separated from Hungary by the Treaty of Peace.

Defence.—Under Article 108 of the Treaty of Trianon the strength of the Hungarian Army (Royal Hungarian Honved) is limited to 1,750 officers, 2,334 N.C.O.'s and 30,916 other ranks—35,000 in all. Up to July 1 1922 the Honved officers had to be recruited exclusively from among former regular officers. The term of service for the rank and file is 12 consecutive years. Only voluntary recruiting is permitted. The army consists of seven mixed brigades; there are also four regiments of Hussars, four batteries, three battalions engineers. A mixed brigade consists of two regiments of infantry (each containing three battalions) one cyclist battalion, one squadron hussars, one artillery group of three batteries, one trench-mortar company, one signals company, one horse-transport detachment, one mechanical transport detachment. Heavy reductions were made on the application of the reconstruction scheme, and it is understood that the permanent establishment of the army in 1926 was much below strength. The police and gendarmerie consists of 2,100 officers and 9,900 men; the term of service is 20 years for the officers and 6 years for the men. See League of Nations, *Armaments Year Book* (1925–6). (X.)

II. ECONOMIC AND FINANCIAL HISTORY

Agriculture.—Of the population of Hungary in 1925 about 56% were engaged in agricultural work as compared with 30% in industry and commerce. Agricultural production was therefore the basis of the country's economic development.

In the five years which preceded the World War, Hungary's agricultural production showed a gradual but constant development in consequence of the draining of flooded areas and the extended use of agricultural machines and artificial manures. This development was arrested by the War, the succeeding revolutions, the occupation of the country by foreign Powers and by the provisions of the Peace Treaty. Owing to the scarcity of labour, draught animals and manure, the arable land, amounting to 5,600,000 hectares, could not be properly cultivated, and a considerable decrease of production resulted. The downward tendency reached its lowest level in the years 1919–20; from that time, progress, at first slow and later quicker, was visible, some crops showing in 1925 a yield which compared well with those of pre-War years.

The index numbers of the five principal crops showing favourable development (the average of the years 1911–5 being equal to 100) are as follows:—

Years	Wheat	Rye	Barley	Maize	Potatoes
1911–5 average	100	100	100	100	100
1920	52	64	66	84	106
1921	79	79	67	67	91
1922	75	79	67	82	68
1923	92	99	75	93	69
1924	70	70	45	125	79
1925	95	96	73	156	118

The following table shows the yield of seven principal crops:—

Crop	Average of the Years		Average of the Year	
	1911–5	in 1920	1921–4	in 1925
	(In metric quintals)			
Wheat	19,950,076	10,322,119	15,812,439	18,942,01
Rye	8,042,139	5,143,169	6,586,079	7,742,2
Barley	7,141,212	4,718,519	4,693,232	5,224,0
Oats	4,404,705	3,237,901	3,187,092	3,560,8
Maize	15,055,696	12,742,081	13,444,601	23,483,3
Potatoes	19,458,893	20,722,294	14,915,207	23,054,7
Sugar Beet	15,019,512	6,398,261	8,706,781	15,252,5

These results are due in part to favourable weather, but cre must also be given to the diligence and perseverance of the peo of Hungary. The abolition in 1923 of export and other ar trary restrictions on trading, and the subsequent stabilisation the currency under the League of Nations reconstruction pl also greatly contributed to increased production by assuring farmer sure markets at stable and profitable prices.

The values in millions of pounds sterling of the seven princi crops mentioned above amounted in 1920 to 14·2, 1921 to 22 1922 to 29·4, 1923 to 33·0, 1924 to 51·6 and in 1925 to 59·1 m lion sterling. Before the War the same seven crops produced the territory of present Hungary (calculated on the basis of prices of 1913) had a value of £48,400,000. The total value of agricultural products for 1925 was approximately £80,000,0 There is no reason to think that the production of 1925 cann be maintained or even improved, provided increased cre facilities for implements and plant are forthcoming.

Live stock, which in consequence of the War and occupatio by the enemy had suffered serious losses, showed in 1925 improvement both from the point of view of quantity and qu ity. Poultry farming also showed great advance after the W While only £700,000 worth of poultry and poultry produ (eggs, feathers, etc.) were exported by Hungary in 1922 the exports approximated to £2,900,000 in 1925. The production wine also showed an increase over pre-War figures for the sa territory, and there was steady development in fruit-growi bee-farming and silk production.

Land mortgage loans granted by the principal financial ins tutions in Hungary amounted in 1913 to £167·7 million, or 4 of their capital. The land mortgage loans granted by the sa concerns at the end of 1924 only amounted to £83,000 or 0· of their capital. In other words, the land in Hungary was pra tically free of all mortgage, owing to the depreciation of t currency. Towards the close of 1925 the 9·3 million hectare land in Hungary were worth £582·2 million, of which the 5 million hectares of arable land were valued at £406·5 millio.

Industry.—The total production of Hungarian industr (present territory) in 1913 amounted to 1,641·4 million go crowns, and in 1924 only 1,531·12 million gold crowns, *i.e.*, 6·5 less. The average production for each factory was 790,000 go crowns in 1913 and only 560,000 gold crowns in 1924, *i.e.*, a di nution of 29·1%. The value of the average working capac of one worker was 7,485 gold crowns in 1913 and only 6,066 go crowns in 1924 *i.e.*, a decrease of 19%.

In the various industries production figures were as follows:–

Industries	Value of Production in Millions of Gold Crowns	
	1913	1924
Iron and metal	252·49	193·58
Machines	251·30	160·49
Stone, pottery and glass	70·87	52·34
Wood and bone	41·42	36·14
Leather, hair and feathers	44·95	51·62
Spinning and weaving	82·24	193·44
Clothing	24·81	31·86
Paper	10·69	7·23
Foodstuffs	695·43	702·55
Chemicals	124·50	84·20
Printing	42·60	18·07

The larger industries showing the greatest progress since the ar are sugar and textiles. In 1924–5 the sugar industry manu- :tured 1,770,000 and exported 892,000 quintals of refined gar, as compared with an output of 1,500,000 quintals in 1923. t of home requirements in textiles amounting to 447,000,000 d crowns, home production in 1925 was able to supply textiles the value of 260,000,000 gold crowns, as compared with only .400,000 pre-War. Next to Minneapolis, Budapest has prob- ly the largest flour-milling capacity in the world, but only out 30% of the capacity was utilised in 1925, owing to lack the grain that formerly came to Budapest from the southern ritories now separated from Hungary.

Foreign Trade.—The foreign trade figures of Hungary for 1925 owed rapid improvement. For the first time since the War ere was a favourable balance in August. The figures for the years ending 1925 are as follows:—

ear	Import	Export	Excess of Import	Increase of	
				Import	Export
	In millions of pounds sterling			Expressed in Index Numbers	
920	17·3	6·8	10·5	100	100
921	21·6	10·5	11·1	125	155
922	22·4	13·7	8·7	129	201
923	17·6	14·1	3·5	101	206
924	29·2	23·9	5·3	168	350
925[1]	30·9	29·2	1·7	179	429

[1] The figures for 1925 are provisional.

The increase of the unfavourable balance in 1924 may be plained by the fact that after the abolition of import restric- ons a great number of goods were imported in a short period. e steady tendency of the commercial balance towards equilib- m was also shown by the decrease of the proportion of the favourable balance to total imports: 60·6% in 1920, 38·8% 1922, 18·2% in 1924 and 5·5% in 1925.

The new international commercial free harbour on the Danube Budapest, which was partly open in 1925 for traffic, is likely be an important aid to increased trade between the Western ates and the Balkans and the Levant.

Employment.—The unemployment returns compiled by the de unions—the only available statistics—showed a reduction m over 36,000 in Jan. 1925 to about 26,000 in Nov. of the ne year. The average wage level for full time was then er 100% of pre-War in gold and between 80% and 90% in me purchasing power.

Price.—The wholesale price index reached its peak at the ginning of 1925 at 159, and the retail index (Pester Lloyd) at 1, exclusive of rent. By Nov. of that year they had fallen to 9 and 123 respectively.

Trade Conventions.—The breaking up of the Austro-Hungarian onarchy, with its single customs union, into seven independ- t customs territories naturally proved a handicap to close de relations between Hungary and her neighbours. In the ginning of 1925 an autonomous customs tariff was brought to force. Although the new duties—partly for the protection home industries and partly as a basis of bargaining—were latively high, there was a marked increase of imports, indi- ting that the duties were by no means prohibitive. By the end 1925 Hungary had concluded commercial agreements with states on the basis of the most-favoured-nation clause, and finitive commercial treaties with five other states on the basis special tariff concessions. Negotiations with other and par- cularly with neighbouring states were proceeding, though owly, with a view to substituting the existing provisional agree- ents by definitive treaties. Among the many obstacles was e unwillingness of adjacent states to avail themselves of the rect transit facilities offered by the Hungarian railway lines. a result of this diversion of traffic to more roundabout routes, couraged by artificial rates, Hungary's ton-kilometre railway ures have fallen steadily—an instance of the problems that confront any solution of the economic difficulties in the Danubian basin.

THE COUNTRY'S FINANCES

Budget for 1924–5 and 1925–6.—The state budget for the fiscal year ending June 30 1925, as approved by the League of Nations, provided for a deficit of £4,200,000. Instead, there was a surplus of about £2,600,000. The budget for the year ending June 30 1926 estimated for a surplus of £1,200,000, although the League of Nations had originally estimated that in this year there would be a deficit of £2,100,000. The results of the first six months of the fiscal year 1925–6 indicated that the more favourable estimates were being borne out by actual results. The principal items of the budget for 1925–6 were as follows:—

Budget headings	Million pounds sterling
Expenditure for material	3·6
State debts	2·4
Treaty charges	0·3
Expenditure for personnel	8·0
Contribution to expenditure of autonomous bodies, comitats, etc.)	1·3
Pensions	3·1
Capital outlay	0·5
Total	19·2
Deficit of undertakings	0·4
Total of expenditure	19·6
Receipts from revenue, etc.	20·8
Surplus	1·2

Both expenditure and receipts showed increases over the League estimates, partly due to the rise of 17% in the value of the crown since the date of stabilisation.

In view of the satisfactory condition of the budget, the League of Nations in June 1925 released for productive capital expenditure 30,000,000 gold crowns from the reconstruction loan which had not been needed, as originally anticipated, to balance the budget, and also agreed that the budget surplus for 1924–5 should be applied similarly and for bringing the salaries of state employees nearer to the pre-War level. In Dec. 1925 the League released from the reconstruction loan a further sum of 20,000,000 gold crowns for capital expenditure in 1925–6; also, conditionally, 50,000,000 for 1926–7, leaving 82,000,000 out of the original loan of 250,000,000 gold crowns still to be released. As at Nov. 30 1925 the commissioner-general's account showed the available balance of reconstruction loan to be 152,000,000 gold crowns.

State Debt.—The total Hungarian state debt amounted to £329,800,000 sterling before the War, which represents a burden of £15·7 *per capita* of population. The debt of present Hungary, as constituted under the Peace Treaty, amounted to £57,600,000 sterling at the end of 1924, due allowance having been made for the allocation of the pre-War debt and of part of the War debt as provided by the Peace Treaty. Of this amount £2,000,000 represents the funded internal debt, £48,700,000 the funded foreign debt and £6,900,000 the floating debt. The burden *per capita* of the population amounts to £7, much less than the pre-War burden, mainly in consequence of the depreciation in the value of the obligations of the state.

Savings and Credit.—Coincidently with the stabilisation of the Hungarian currency on the £ sterling there was a marked increase in savings deposits. Figures from the postal savings banks and the 13 principal financial institutions in Budapest show that savings deposits steadily increased from £210,063 at Dec. 31 1923 to £5,012,500 in Nov. 1925, while current account deposits with the same institutions and over the same period increased from £4,876,952 to £13,029,166. The gross total of deposits is only about one-quarter of the pre-War amount.

The bank rate, which in March 1925 was 12½% was gradually lowered until in Oct. 1925 it reached 7%, credit and money conditions becoming correspondingly easier. This was facilitated by the introduction of foreign capital. In addition to relatively large short-term commodity credits for flour, sugar, etc., principally from England, and the participation of foreign capital in two of the leading Budapest banks, two long-term foreign loans were successfully floated towards the end of 1925, one of $10,000,000 in New York for 48 Hungarian municipalities, and another of £1,000,000 sterling in London against land mortgages.

Taxation.—Prior to the period of reconstruction in 1924 the Hungarian Govt. had recourse to many taxation expedients and drastic measures in their struggle to maintain revenue in the face of an ever-depreciating currency. The system of assessing taxation on the incomes and revenues of the previous year soon ceased to have any meaning. As a result of the War, the revolution and the Rumanian occupation there were also outstanding arrears due for some three or four years. In 1920 there was a forced loan by the stamping of notes amounting to 50% of the currency then in circulation, in 1921 a heavy capital levy, and in 1924 another forced loan based on the earned income and capital of each individual or firm operating in Hungary. Consumption (excise) taxes were fixed at a proportion of the actual price of the articles consumed, and the "turn-over" tax, payable simultaneously with the purchase of all articles, was introduced. The latter tax was fixed originally at 1·5% and subsequently at 3% of the sale price of each article and on each handling, thus amounting in many instances to a tax of 12%. (In Aug. 1925 this tax was reduced to 2%.) Arrears of taxation were drastically compounded, and land taxes were made payable in wheat or wheat values. Finally, by the passage of Act IV. of 1924 the Government were empowered to levy all taxes in values of gold crowns.

In a report presented to the League of Nations in Oct. 1925, the League commissioner-general in Hungary estimated that on the Hungarian Budget for 1925–6 the taxes levied by the state, excluding local taxes, amounted to 60 gold crowns *per capita* of population. This compared with approximately 45 gold crowns *per capita* pre-War, which, after making allowance of 35% for the depreciation in the value of gold, also worked out at 60 gold crowns *per capita*. Adding local to state taxation, the commissioner-general estimated that the total *per capita* taxation was 72 gold crowns per head. Estimating the national income of Hungary at approximately 3,600 to 4,000 million gold crowns, the commissioner estimated that the total taxation of Hungary represented between 14 and 17% of the national income. This compared with between 13 and 14% pre-War. According to the same authority this taxation was by no means light for an agricultural country such as Hungary. From one-fifth to one-quarter of these taxes were raised in 1925 by direct and from three-quarters to four-fifths by indirect taxation.

On the basis of the Government assessment for the fiscal year ending June 30 1926 the direct taxes, according to Commissioner-General Smith, were divided as follows:—

	Millions of gold crowns
Land tax	42
House tax	24
State participation in house rents	23
Corporation tax	10
Income tax	41
Property tax	8·7
	148·7

The estimates of indirect taxation for the same period are as follows:—

Turnover tax	103·6
Stamp and other similar taxes	52·4
Tax on commodities	55·6
Customs	85·6
Salt monopoly (net)	11·2
Tobacco monopoly (gross)	97·6
Transport tax	9·2
	415·2

Currency.—During the existence of the Dual Monarchy, Hungary and Austria had a joint monetary system and a joint bank of issue. After the outbreak of the revolution the Austro-Hungarian Bank was able for some time to continue its work in Hungary, but the Bolshevik régime seized the entire stock of notes. When these began to run short the so-called soviet republic issued their own notes. After the collapse of soviet rule in 1919, the Hungarian Govt. issued the necessary decree to enable the Austro-Hungarian Bank to continue its statutory work as "Manager of the Hungarian business of the Austro-Hungarian Bank."

In March 1920 the Government ordered the stamping of the notes of the Austro-Hungarian Bank which were in circulation within the country, and requisitioned 50% of these notes as a forced loan in order to secure, so far as possible, the carrying on of the state administration without constant application to the note printing press. As the creation of a special issuing institution appeared to be inevitable in consequence of the liquidation under the Peace Treaties of the Austro-Hungarian Bank, the state itself provisionally established the Royal Hungarian State Note Institute (M. Kir. Állami Jegyintézet), which began its activities on Aug. 1 1921. The notes of the Austro-Hungarian Bank, which had been provided with the Hungarian stamp, were exchanged in the same year against state notes.

When the State Note Institute commenced its work, the financial and economic position was such as to compel the state to cover its budgetary requirements not from revenues but by means of the note printing press. This naturally resulted in the gradual depreciation of the crown. The forced loan raised by stamping notes had covered the budget deficit only for a short time. In 1921 the Government had recourse to a non-recurring capital levy, but by the time most of the proceeds reached the Treasury the value of the crown had so depreciated as to nullify these efforts. In the first half of 1921 the exchange rate of the crown rose temporarily in Zürich from 1·05 to 2·85 Swiss francs (100 crowns), owing to the impression created by the taxation and other plans of the then Minister of Finance, M. Hegedus. When it was seen that these plans were impossible of realisation, and as Hungary's balance of payments became more and more unfavourable, the crown continued to fall, until in March 1924 it reached 0·0085 Swiss francs for 100 crowns. As the result of lo negotiations the League of Nations loan was raised, and the restor tion of normal economic and currency conditions was thus ma possible (*see* above, *Political History*). All restrictions in forei exchange were abolished in Oct. 1925, when the currency was co sidered to be sufficiently stabilised to be left to fluctuate fre according to supply and demand.

Central Bank.—The re-establishment of an independent bank issue was in the forefront of the programme of reconstructio The Hungarian National Bank was founded, with a capital 30,000,000 gold crowns, and commenced its activities on June 1924. From that day the state notes then in circulation were garded as bank-notes. Under its statutes the bank is precluded fro lending to the state, and is required to maintain against its no circulation a percentage of cover in precious metal and stable forei exchanges, on an ascending scale, beginning at 20% during the fi five years. The bank return of Dec. 31 1925 showed the proporti of cover to be 56·46 per cent. Since July 1924 the currency has be stable on a sterling basis. In Oct. 1925 the basis of stabilisati became gold, and all restrictions on dealings in foreign exchange we abolished.

The following table shows the development of the note circul tion:—

Date	Issuing institution	Circulation in paper crowns
Dec. 31 1920	Hungarian management of Austro-Hungarian Bank	14,307,808,630
Aug. 1 1921	State Note Institute	15,787,175,750
Dec. 31 1921	State Note Institute	25,174,941,187
Dec. 31 1923	State Note Institute	931,337,334,630
June 24 1924	Hungarian National Bank	2,520,113,700,576
Dec. 31 1924	Hungarian National Bank	4,513,989,561,419
Dec. 31 1925	Hungarian National Bank	5,193,937.447,500 (415,514,995·79 pengös)

New Currency.—On Dec. 31 1925 the currency *per capita* of th population was approximately 43 gold crowns. In the latter part 1925 the new monetary unit was chosen and named the pen divided into 100 fillér; 3,800 new units go to one kilogramme of fi gold, so that 1 pengö contains 0·26315789 grammes of fine gol The Currency Reform Law passed on Nov. 6 1925 provides for th minting of gold coins for 20 and 10 pengös from an alloy consistin of 900 parts of gold to 100 of copper, so that 3,420 pengös will struck from one kilogramme of this alloy. The National Bank required to buy gold in bars at a fixed price without limit and demand. Silver coins of one pengö will be put into circulation to total nominal value of not more than 45,000,000 pengö.

From Jan. 1 1927 the pengö will be the obligatory unit of accou in Hungary. The rate of conversion from the old to the new curren is 12,500 paper crowns to one pengö, or one gold crown = 1·15853 pengö. 1 pengö is therefore equal to 0·0359388 pound sterling, 0·1748985 dollar.

HUNTING: *see* FOX HUNTING: SHOOTING.

HUSAIN IBNA‘LI (*c.* 1854–), Amir of Mecca from 190 to 1916 and King of Hejaz from 1916 to 1924, was the second so of Muhamnad Ibn‘Aun of the ‘Abadila clan of Ashraf. He wa brought up in Bedouin surroundings, but spent a great part his life at Constantinople. Reputed to harbour Anglophil tende cies, he was deeply versed in the byways of Ottoman politi and his best trait was a profound knowledge of the desert, f which he always maintained a genuine affection. At the begi ning of his Amirate he won golden opinions by his sagacity an modesty and set himself vigorously to forward Turkish interest in Arabia. In 1910 he subdued a rebellion in ‘Asir and subs quently invaded Qasim without result, but in 1913 he began show his true colours by opposing the extension of the Heja Railway to Mecca.

When the World War broke out he entered into negotiatio with the British, which culminated in the Arab revolt in Ju 1916. In Oct. he proclaimed himself "King of the Ara Countries" though he was formally recognised only as Ki of Hejaz. At the Versailles Peace Conference (1919) he w represented by his third son, Faisal, but refused to ratify th treaty as a protest against the mandatory *régimes* imposed Syria, Palestine and ‘Iraq. Subsequently his domestic polic was marked by ever increasing avarice and reaction, while wed the seeds of future trouble by deliberately courting the mity of Ibn Saʻud. In March 1924, while on a visit to Trans-dan, he proclaimed himself Caliph, but war with Ibn Saʻud s already imminent and the Wahhabi attack on Zaif in Sept. ınd him unprepared. On Oct. 5 he abdicated and proceeded ʻAqaba, whence in July 1925 he was conveyed by a British rship to Cyprus, where he took up his residence.

By his first marriage Husain had three sons: ʻAli; ʻAbdullah, nir of Transjordan, and Faisal. The first of these, ʻAli Ibn ısain, who was born about 1880, took no conspicuous part in airs during his father's Amirate. After the World War he be-me Amir of Medina and in that capacity did much useful work connection with the reconstruction of the Hejaz Railway. In 24 he was pressed to accept the Amirate of Transjordan but clined in favour of returning to Medina. He succeeded his her as second King of Hejaz on Oct. 3 1924, but abdicated on c. 19 of the following year (*see* HEJAZ) and returned to Bagh-d to live as the guest of his brother Faisal.

HURGRONJE, CHRISTIAAN SNOUCK (1857–), Dutch entalist, was born at Oosterhaut Feb. 8 1857. After com-ting his studies in theology and Oriental languages he went Arabia, where he stayed for several years, and to other parts the Near East. The result of these travels was his work *ekka* (2 vol., 1888–9). He refused a nomination as professor Arabic at Cambridge University in succession to Robertson nith and also nominations in Germany and at Leyden, pre-ring to continue his studies on Islam in the Dutch East Indies 889–1906) where for some years he was counsellor to the overnment in Mahommedan affairs. In 1893–4 he published *Atjehers*, which was translated into English in 1900. He turned to Holland in 1906, where he accepted the chair of abic at the University of Leyden; in 1907 he was nominated unsellor for Indian and Arabian affairs to the Dutch and the ıtch East Indies Government. Among his other works are *Ned-and en de Islam* (1911); and *Verspreide Geschriften* (1923ff.).

HUTCHINSON, SIR JONATHAN (1828–1913), British surgeon *e* 14.13), died at Haslemere, Surrey, June 23 1913.

HUTMENTS: *see* BARRACKS.

HUYSMANS, CAMILLE (1871–), Belgian politician, was rn at Bilsen in Belgian Limbourg May 26 1871. After gradu-ing in Germanic philology at Liége, he became a professor, st at the Collège Libéral at Ypres, and then at the Université ouvelle, Brussels. He edited the *Petit bleu* and the *Peuple* and ter the War started the *Volksgazet* in Antwerp. He entered the ıamber in 1910, first as deputy for Brussels and then for ıtwerp, where he became an alderman of public instruction. 1914 he was secretary of the Socialist International party and ıile in Holland endeavoured to organise a congress at Stock-lm. Though he was severely criticised for this by his fellow cialists at the time, he completely regained their confidence ter and became the chief organiser of the Socialist party in ıtwerp. In June 1925 he became Minister of Science and Arts M. Poullet's Government. His chief works are: *Limburgsch ıarboek* (1891–5); *Zoponymische studie over Bilsen* (in conjunc-on with J. Cuvelin) 1897; *Stockholm* (1919); and numerous cialist brochures.

HWANG-HO (*see* 14.23).—A reconnaissance of the flood-ricken delta of the Hwang-Ho was undertaken by the Ameri-n Red Cross in 1911 and 1914; a promising series of observations the Kiang-Hwai engineers under H. E. Chang Chien was gun in 1911, and a critical review of these previous findings as made in the field in 1919–20 by John R. Freeman, partly connection with his work for the Grand Canal Improvement oard.

Through the province of Shantung the Hwang-Ho's fall to e sea has been found to be about 1 in 5,000, a steep gradient r so large a river. The current is therefore very swift, and the ver not only carries along great quantities of sediment, but e muddy bottom itself steadily works forward and the bed of e channel is raised. Measurements by Freeman's staff show at the river carries over 4% *by weight* of silt, and may even rry 13% in greatest flood. Naturally the stream drops a part of its heavy burden whenever its velocity decreases. Three types of deposit are to be considered: outside the outer dikes; between the dikes; and along the river bed within the main channel.

Deposits outside the Outer Dikes.—When the river overflows or breaches the outer dikes, it deposits over the land a sloping ridge of sediment which varies greatly in size, but probably during the past 1,000 years has not exceeded the equivalent of 10 ft. close to the main dike, tapering off to almost nothing at 5 or 10 m. away.

Deposits between the Inner and the Outer Dikes.—Whenever the river floods the space between the outer and inner dikes, the waters as they subside deposit their silt and a flood plain is formed. These flood plain deposits between the dikes, while varying from 12 to 20 ft., average 15 ft. above the low-water level. Probably they accumulate somewhat rapidly. It is this very action which can be utilised to form a permanent barrier of surpassing strength if the river be trained as Freeman suggests (*Proc. Amer. Soc. Civil Engineers*, May 1922, pp. 1113–67).

Deposits within the Main Channel.—When the summer floods subside, the river, in narrowing to its winter channel, slows up and deposits sediment on its own bed. Although much has been written about the Yellow river continually raising its bed, compelling the inhabitants constantly to build the dikes higher, there were no facts upon which to base such statements until the Red Cross in 1914, and the Grand Canal Improvement Board in 1919, gave cross sections, extending far beyond the dikes, showing broadly the relation of the elevation of the river bed to that of the adjacent country. These show that the river has done remarkably well in conveying nearly all of its silt to the sea, and that the rise of its bed has been extremely slow, in general not more than 15 ft. during the past 1,000 years, or perhaps 2,000 years—say a foot a century. Great as the river's land deposits have been, they are small in comparison with the total volume of sediment transported in 1,000 years, if the river during that time carried anything like the percentage of sediment recently observed. It appears that the Yellow river during all the historic period has carried to the sea 99% of the burden of silt gathered in the loess country.

The flow of the Yellow river varies much with the season, being ordinarily three times as great in flood as at low water. In the summer of 1919 a flood flow of 265,000 cu. ft. per sec. was measured (the highest for 10 years) with a minimum of 10,600 cu. ft. per second. This is remarkably small, considering the great extent of the drainage area; much of it, however, is a land of little rain, and the losses on the way are very large. Moreover, this river has no tributaries for some 300 m. from its mouth. Its only connections are with irrigation and navigation canals which serve during high-level periods to draw off water. Though practically useless for navigation, the Yellow river may, in spite of its relatively small discharge and variable flow, be a blessing in the way of drainage and irrigation if it is properly dealt with. (C. K. E.)

HYATT, ANNA VAUGHN (1876–), American sculptor, was born at Cambridge, Mass., March 10 1876. Educated at a private school at Cambridge, she commenced the study of art in Boston, proceeding later to New York City. There she studied a short while with H. A. MacNeil and Gutzon Borglum, under whose influence she acquired that knowledge of horses which is so signally exemplified in some of her works. She devoted herself chiefly to small bronzes. Her equestrian statue, "Jeanne d'Arc," was selected for Riverside Park, New York City, in 1915, and copies of it were erected at Gloucester, Mass., and Blois, France. This work, a "Saint Joan of Arc" in the Cathedral of St. John the Divine, New York City, and a "Diana" have been her chief figure compositions. Notable among her other works is a colossal "Lion on a Boulder" executed for the Dayton High School. In 1923 she married Archer Milton Huntington.

HYDE, DOUGLAS (1860–), Irish scholar and writer, was born at Frenchpark, Co. Roscommon, 1860, and was educated at Trinity College, Dublin. In 1891 he acted as interim professor of modern languages at the University of New Brunswick, Canada. He formed in 1893 the Gaelic League, for the preservation and extension of the Irish language, and was president of that body until 1915. In 1899 his production, before a vice-regal committee on education, of letters from leading Celtic scholars throughout Europe saved the Irish language on the intermediate board which regulated the curricula for Irish schools. During 1905 he toured America and raised £11,000 for the Gaelic League. On his return he was appointed a member of a royal commission on Irish university education. Dr. Hyde was made professor of Modern Irish at University College, Dublin, in

1909. He was co-opted by the Free State Senate in 1922, but failed to secure re-election in 1925. In the latter year he became editor of *Lia Fáil*. The movement created by him initiated an enthusiasm for the native language, which finally resulted in the teaching of the language being made compulsory in Irish schools.

Among Dr. Hyde's more important works are *A Literary History of Ireland* (1899); collections and translations of the *Love Songs of Connacht* (1893); *Raftery's Irish Songs* (1904); *The Religious Songs of Connacht* (1906). He also wrote several short plays in Irish.

HYDERABAD, SIR MIR OSMAN ALI KHAN, Nizam of (1886–), was born April 6 1886 and succeeded his father, Sir Mir Mahbub Ali Khan, on his death on Aug. 29 1911. His education had been under an English tutor, Sir Brian Egerton, and a nobleman of the state, of scholarly attainments, Imad ul Mulk (Saiyid Husain Bilgrami). Soon after accession he abandoned the traditional system of governing through a Diwan, and for five years was his own prime minister. In 1919 he constituted an executive council with a president and eight other members, each in charge of one or more departments. During the World War he enjoined on his subjects the duty of firm and steadfast devotion to the British cause and prohibited anti-British propaganda in his dominions. The War expenses of the state amounted to over three-fifths of the annual income. His Highness, already a G.C.S.I., was awarded the G.B.E., was promoted to hon. lieutenant-general in the British Army, and in 1918 King George V. conferred upon him the new and special title of Exalted Highness.

HYDROELECTRIC ENGINEERING.—The extent to which the water powers of the world have been investigated and developed during the past decade forms one of the striking engineering features of the period. Although falling or flowing water formed the earliest of the natural sources of energy to be utilised for providing power, some two-thirds of the water power at present in use has been developed since 1910.

The reasons for this are partly technical and partly economic. The technical development of electric generation and transmission has made it economically possible to utilise powers remote from any industrial centre, while the great developments in electrochemical, electrophysical and metallurgical processes have provided an outlet for such energy as could be cheaply developed. Most of these processes require relatively large amounts of energy, and all are economically dependent on the cheapness of this energy. They have created a demand for large blocks of cheap power which can, under favourable circumstances, be satisfied more readily from a water-power installation than from any other source.

Developments.—The urgent demand for energy to supply the abnormal requirements of the War period, combined with the increased cost of fuel, was responsible for an unprecedented rate of development in those countries having available water-power resources and normally dependent on imported fuel. Thus in France something like 2,500,000 of water-horsepower is now developed as compared with 750,000 H.P. in 1914. In Switzerland, the present output is 1,500,000 H.P. as compared with 880,000 H.P. in 1914. In Italy it is estimated that the total output will shortly amount to 3,000,000 horsepower. Japan, which only recently began to investigate her water-powers, has, since 1916, developed over 1,200,000 H.P., or about 20% of her available resources. Step by step with developments on the electrical side, advances have been made in the design of hydraulic turbines. These various developments have made it commercially possible to make use of large water-power at sites quite remote from any centre of industrial activity. In many cases industrial communities, attracted by the cheapness of the power, have grown up around such sites. In others the energy has been transmitted electrically for long distances, in some cases between 200 and 300 m., to some more convenient centre.

Available Water Power.—An estimate, based on papers presented to the World Power Conference at London in 1924, and on other sources, indicates that the amount of water-power, respectively available and developed in some of the chief cou tries of the world, is approximately as follows:—

Millions of Horsepower			
		Available	Developed
Great Britain		0·9	0·25
Canada		23·0	3·28
Remainder of British Empire including	Australia	35·0	0·7
	Africa (East)		
	Africa (South)		
	Africa (West)		
	British Guiana		
	India and Ceylon		
	New Zealand		
	Papua		
Austria		3·7	0.28
South America		54·0	0·42
Dutch East Indies		8·0	0·08
France		4·7	2·5
Germany		1·5	0·75
Italy		5·4	2·5
Japan		6·4	1·5
Norway		13·3	1·32
Russia		20·0	0·83
Spain		6·0	1·26
Sweden		8·8	1·42
Switzerland		4·0	1·49
United States		28·0	9·8

From these figures it appears that some 200,000,000 H. is available, of which approximately 27,000,000 is at prese developed or in course of development.

Uses of Hydroelectric Energy

While a large proportion of the energy developed from wate power is utilised for industrial purposes and for lighting an traction, an increasing proportion is being used for pulp an paper making and electrochemical and electrometallurgical proc esses; indeed the chief outlet for hydroelectric power in th near future is likely to be in connection with such processes an probably, railroad electrification. The amount of power alread used in electrochemistry is large. Thus the world's productio of calcium carbide alone requires some 500,000 H.P. and whe it is remembered that such products as aluminium, carborun dum, chromium, cyanamide, caustic soda, chlorates, magnesium phosphorus and silicon are only rendered commercially possibl by such processes, it will be realised that the future demand fo energy for their manufacture is certain to be large. Nitroge fixation is also likely to make great demands. In Norway alon some 400,000 H.P. is available for this purpose, and in view o the rapid depletion of the natural nitrate deposits, from whic four-fifths of the world's nitrogen consumption has hitherto bee supplied, and of the diminution in fertility of many of the grea wheat and cotton growing areas of the world, the production o artificial fertilisers by one or other system of nitrogen fixatio must, in the near future, become a question of great importance

Railroads.—The electrification of railroads has made rapid strides of recent years. In the United States some 3,300 m. o track have been electrified, while the Chicago, Milwaukee and St. Paul Railway has the longest electrified section in the world (850 m.), the power for operation being obtained from hydro electric stations. In France, much of the track of the Compagnie du Midi in the region of the Pyrenees has been electrified with the aid of water power, and it is anticipated that the whole system of about 3,000 km. will be electrified within 10 years.

The hydroelectric stations supplying these lines have a capacity of close on 300,000 horsepower. The Orleans Co. has a scheme for electrifying 3,000 km. of its lines, part of which is to be supplied from hydroelectric stations having a capacity of about 210,000 horsepower. In Austria some 1,800 km. of line is in process o electrification for which 120,000 H.P. is available from hydroelectric stations. In Germany about 1,200 km. is now electrified, its electricity coming from hydroelectric schemes. Much of the Swiss Railway system has been electrified, and the electrification of further trunk lines in these and other countries at present under consideration. Such developments will open a very large field for the utilisation of water-power where this available. (*See* RAILWAYS, ELECTRIFICATION OF.)

Agriculture.—Much energy is now being utilised in the United ıtes of America for purely agricultural purposes. In California, example, there is in effect one vast system of electrical supply :ending over a distance of 800 m. with 7,200 m. of high-tension ınsmission lines. This is fed from 75 hydroelectric stations interınected with 47 steam plants, to give a total output of 785,000 rse-power. A further group of 13 hydroelectric schemes now der construction will add another 520,000 horse-power. A large portion of this power is used in agriculture, and it is estimated ıt electric motors equivalent to over 500,000 h.p. are now talled on Californian farms. The Californian rice industry is nost wholly dependent on irrigation made possible by electric mping, whilst most of the mechanical processes involved in ming are being performed by electric power.

The economic development of many of the tropical dependcies of the British Empire, whose latent wealth is practically tapped, is directly inter-connected with the development of ɛir water-power resources. Not only would an abundant sup-of such power enable railroads to be operated, irrigation ıemes to be set on foot, and mineral deposits to be tapped and rked, but it would go far toward solving the labour problem ich promises to be one of some difficulty in the future.

While those outlets for electrical energy which are now in ht promise to absorb all the energy which can be cheaply veloped for many years to come, there are many other proble directions in which such energy might find a new and profble outlet. Among these may be mentioned the purification municipal water supplies; the dehydration of food products; d the preservation of timber.

LAY-OUT OF HYDROELECTRIC SCHEMES

High Head Schemes.—The layout of a hydroelectric scheme pends on the physical characteristics of the catchment area l site. High head schemes are of necessity located in mounnous country and are usually fed from streams of relatively all volume. Owing to this a comparatively small reservoir is en sufficient to provide sufficient storage of the head waters give uniform output over a considerable portion of the year a reasonable cost. The water may be brought directly from reservoir to the power house through a pipe line or pressure ınel if the gradient is suitable. Often, however, it is possible bring it through an open canal at a very flat gradient, to a ebay on the hill-side above the power-house, whence a short pe-line conveys it to the turbines.

Low Head Schemes.—Low head schemes are usually located on ers where the gradient is small, the head being provided by a m, or naturally by means of rapids or a waterfall. A river m, by raising the natural level of the water, provides a cern amount of storage, but seldom more than is sufficient to ore the night flow for use during the day. Such a scheme can erefore only give a continuous output equal to the dry weather pacity of the river, unless operated in conjunction with some am station capable of equalising the output at such times.

Several types of low head layout are available. Where a dam built, the power house is often constructed on one flank of the m with a short head race or tail race as is most convenient, d the dam itself is used as a spillway over which excess water discharged in times of flood. Where the river flows in a narw and steep gorge the power-house may sometimes with vantage be constructed in the dam itself, which now consists a hollow reinforced concrete structure. Where the river forms ong bend, it is often possible to cut across the neck of the nd and to utilise the head between the two points.

Medium Head Schemes.—In medium head schemes—utilising tween 40 and 200 ft. head—the layout is usually similar in oad outline to those involving either high or low heads. Where ch a scheme involves the use of a long closed supply pipe to turbines, having only a small gradient, somewhat special atment, however, becomes necessary. Owing to the large inertia of the column of water in the pipe line, any sudden demand for water caused by opening the turbine gates on an increasing load causes a relatively large drop of pressure at the turbines, which renders governing very difficult. To reduce this difficulty, a surge tank is fitted to the pipe-line at a point as near to the turbines as possible. This is a stand pipe surmounted by an open tank having a comparatively large surface area, whose upper level is slightly higher than that of the water in the reservoir. Any sudden demand is then supplied in part by flow down the stand pipe and the drop of pressure is greatly reduced. At the same time any rise in pressure caused by suddenly closing the turbine gates is also reduced.

In a low head station the available space is usually limited by the width of the dam on which it is built. In consequence, in such plants, there is a tendency to locate the switch gear and transformers either on floors above the machine-room, or, as is becoming more common, in an entirely separate building on the river bank. In some few cases all the transformers and high-tension switch gear are out of doors, and this will probably become standard practice in the future. It has even been proposed to place the whole generating plant outside, merely providing a portable cover for use during repair work. The recently planned Muscle Shoals development in Alabama was originally schemed along these lines. It has finally been decided to adopt the conventional type of station building, but the complete outdoor generating station will doubtless arrive in the near future.

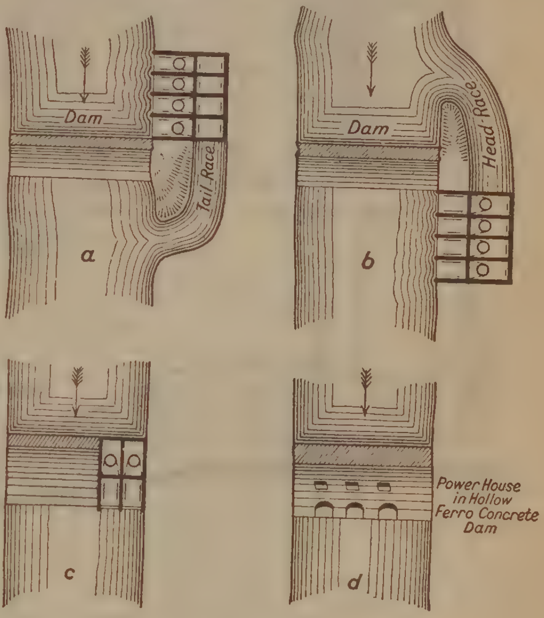

FIG. 1.—Types of Low-head Development.

Turbines.—The inward flow pressure turbine and the Pelton wheel are the only types of turbine used in modern hydroelectric schemes of any size. The type to be adopted depends largely on the available head. The Pelton wheel is a slower running machine than the pressure turbine and is therefore better fitted for very high heads. It has the further advantage for such heads, that since the water is discharged through one—or at the most two—nozzles, these may be of reasonable size when dealing with the small volumes of water normally available in high head schemes. The pressure turbine on the other hand with its full peripheral admission of water is well adapted to utilise the large volumes necessary in low head schemes, and its higher speed of rotation is also a great advantage in low and medium head plants, in enabling the cost of the electrical generators to be reduced. Broadly speaking the Pelton wheel is more suitable for heads above about 700 ft.; the pressure turbine for heads below about 250 ft. in small units and below about 500 ft. in large units;

while over the intermediate range of heads much depends upon the size of the units and the special circumstances.

All modern pressure turbines are of the mixed flow type, having inward radial flow through guide vanes surrounding the runner, and axial discharge. Pivoted guide vanes are universally used, speed regulation being attained by simultaneous rotation of these about their axes. Low head turbines—up to about 40 ft. head—are usually set in an open forebay. Either vertical or horizontal shaft machines may be used, but the former are becoming more common, especially for large units. For higher heads the water must be supplied through a pipe-line and the turbine is enclosed in a spiral casing so designed as to distribute the water evenly around the periphery of the guide vane ring. For heads up to about 120 ft. this casing may be moulded in concrete, but for higher heads and pressures a metal casing becomes necessary. This may be of cast iron, cast steel or of steel plate construction, and in order to give rigidity and increased safety in case of surges of pressure is sometimes embedded wholly or partially in the concrete of the substructur
Modern development is tending in the direction of units havin
a single runner and a vertical shaft on the top of which th
electrical generator is mounted. The weight of the shaft, runne
and generator is then carried from a single thrust bearing of th
Michell or Kingsbury type. This type lends itself to a simpl
and efficient form of setting, while the friction losses are extremely low.

One of the great drawbacks of the low head turbine in th
past has been its relatively slow speed of rotation, which necessitated either a slow speed and costly generator or expensiv
gearing. As a result of experiment it has, however, been possibl
so to modify the form of the runner as greatly to increase th
speed of rotation under a given head without seriously reducin
the efficiency.

Such runners are characterised by their small number o
vanes—often not more than four being used—and approximat
in form to that of a marine propeller. In one of the latest types

Kaplan, the vanes are capable of rotation about their own s so as to enable the vane angles to be adjusted to suit the ying flow of water at part loads. Further developments in the ection of increasing the speed are in active progress and mise to give important results. At the present time, howr, turbines are in existence which are capable of efficient ration at speeds at least three times as great as would have n thought possible 10 years ago.

The pressure turbine is now built in units capable of develop- upwards of 70,000 H.P. under a head of 300 ft., and this size ld readily be increased if necessary. If well-designed and talled in a suitable setting the efficiencies are remarkably h. Efficiencies of 93 % have been obtained on tests of vertical ft turbines at Niagara and values approximating 90% are te common. In a medium head plant the following are typical ues:—

raction of full load . . .	·25	·5	·75	·90	1·0
ercentage efficiency . . .	70	82	88	90	88

Pelton wheels are usually built as horizontal-shaft units with or two nozzles, and in sizes up to about 30,000 horse power. eed regulation is usually performed by a deflector which cuts the jet from the wheel, acting in conjunction with a central dle or spear which slowly reduces the size of the jet while the lector returns to its original position. The mechanism is rated by a relay cylinder supplied with pressure water or oil ough a pilot valve actuated by the governor. In a well-signed plant the instantaneous speed variation corresponding a sudden application of full load should not exceed 12 to 15%. e difference between the initial and final steady speeds should exceed 2% between full load and no load, and should not eed 5% with a load variation.

At constant speed the efficiency of a Pelton wheel falls off nparatively slowly as the load is diminished. A well-designed eel should have approximately the following efficiencies:—

raction of full load . . .	·25	·50	·75	·99	1·0
ercentage efficiency . . .	77	83	85	86	83

The lack of a suitable pipe-line has, until recent years, tended retard the development of plants for very high heads. Under h heads the necessary wall thickness, even with a moderate e diameter, becomes too great to permit of the use of riveted nts. Recent developments in electric welding and oxyacetye welding have, however, rendered it possible to construct table welded pipes and by their aid, and by the use of solid wn steel pipes in extreme cases, it has been found possible harness some very high falls. The highest as yet utilised is the Fully installation in Switzerland. Here the working head is 12 ft., corresponding to a working pressure of 2,360 lb. per sq. h. The pipe-line is 19.7 in. in diameter and 1¾ in. thick at its ver end, and each of the three Pelton wheels in the power-use develops 3,000 horsepower.

Pipe-lines.—The pipe-line for a water-power plant may be nstructed of steel, reinforced concrete or wood. Steel is the st usual, riveted pipes being suitable for all but the highest ads. For heads up to about 200 ft., reinforced concrete pipes are table and have the advantage of not deteriorating appreciably th age. As compared with steel pipes the materials are more sily transported and the friction losses are less. Large pipes moulded in site, and as the bulk of the materials is usually tained locally, only the cement and reinforcement require be transported for any distance. For small diameters, pre-ulded concrete pipes with loose-sleeve or spigot-and-faucet nts are often used.

For moderate heads, wooden pipes are extensively used in ntries where suitable timber is cheaply available, and under ourable conditions have a useful life of at least 25 to 30 years. ey are built up of wooden staves about 6 in. wide, shaped to correct radius and jointed end to end by thin metal plates ven into saw cuts on both the abutting ends, covering the nt. The staves are so arranged that the circumferential joints are not continuous. They are held together by circumferential steel bands which resist the bursting pressure, and whose diameter and spacing depends upon the pressure to be anticipated in each section of the pipe. The materials are easily transported and neither erection nor repair require any great degree of skill. If suitable timber is available the mill can be set up on the site and only the bands and shoes require transporting.

As heads and diameters increase the amount of steel necessary for the bands increases until it becomes comparable with that required for a steel pipe for the same duty. In general the range of useful heads is from 20 to 200 feet. These pipes have been constructed in sizes up to about 18 ft. in diameter.

Generation and Transmission.—Generators to be driven by hydraulic turbines range from the simple open-type machine which is often applicable to small units, to constructions approaching those of steam-turbine driven alternators, which are necessary for the largest high-speed machines.

At the present time the energy is almost universally generated as alternating current, on account of the simplicity and reliability obtained with a moderate generating pressure which is readily transformed to the highest pressures which may be required for economical transmission. Occasionally, however, the advantages of high-tension direct-current transmission may outweigh the essential difficulties of its generation, in which case the Thury system is available. Of the two types of alternating current generators, the synchronous and induction types, the latter has come largely into use in recent years, especially for automatic stations, on account of its robustness of construction and simplicity in operation.

Frequencies.—The question of the most desirable frequency is simplified by the fact that in most countries two frequencies—a high and a low—have become recognised as standard. In the U.S.A. and Canada, either 60 or 25 cycles per sec. is almost universally adopted; on the Continent 50, 16⅔ and 15; in Great Britain and South America 50 and 25 cycles. As regards the number of phases there is little freedom of choice, the question being largely determined by the nature of the load. Single phase supply, though offering some advantage in simplicity of equipment, involves increased losses in the generators and generally less reliable performance. This system is only used where absolutely necessary, as for direct supply to alternating current railways using commutator motors. Of the polyphase systems, three-phase is preferable to two-phase for general power purposes, since the plant is more fully standardised and therefore cheaper, while rotary converters are smaller, more efficient, and give better commutation on three-phase than on two-phase systems.

Distribution.—For distribution within a short radius of the power-house the voltage of generation and transmission will be the same as that required for the supply to consumers; but for transmission to greater distances, for which the voltage is stepped up, there is a wide choice of the voltage of generation. An unduly low voltage involves heavy and expensive bus-bars and switch-gear, and in large units presents difficulty in the construction of the stator windings of the generators. A very high voltage, on the other hand, requires a winding with many windings in series per slot, a greater thickness of insulation and involves a generally reduced reliability. From the point of view of the construction of the generator it is desirable to have two conductors per slot, and the stator current should then vary from about 300 ampères in the smallest to 1,000 ampères in the largest machines. It may therefore be shown that the most suitable voltage of generation, when not otherwise restricted for a three-phase machine, should vary approximately as follows:—

Output (kw.) .	200	500	1,000	2,000	5,000	10,000	15,000
Pressure (volts)	450	900	1,500	2,500	5,000	9,000	11,000

The power factor is here assumed to be 0·8. For two-phase machines the phase pressure should be about 0·9 times the above values.

One of the most important modern developments in transmission has been in the direction of reducing the losses by increasing the voltage of the transmission lines. (*See* ELECTRICITY, TRANSMISSION OF.)

Automatic Generating Stations.—The automatic generating station is especially suited to systems where numerous small-power falls are available. In such a case the expense of an operating staff at each would be prohibitive, but if each station can be made automatic, and all are linked into a common distribution system, the labour cost is reduced to a minimum. The first of such stations was set in operation in 1917. This is on the system of the Iowa Railway and Light Co., where it operates in parallel with a steam plant situated about two miles away. The automatic station contains three 500-K. V. A. generators driven by Francis turbines operating under a head of 10 feet. Normally the starting and stopping of these sets is accomplished automatically through the medium of float switches actuated by the change in the level of water above the dam. Provision is also made for controlling these operations as well as the gate openings of the individual turbines by push buttons in the central power-house. Other plants of this type have since been installed, and this method of development promises to do much to render it economically possible to utilise many low head river falls which have hitherto been neglected.

Combined Operation of Hydraulic and Steam Plants.—Owing to the variability of river flow, it is impossible to utilise more than a fraction of the total available energy unless machinery is installed which will have to be idle during the greater portion of the year. Broadly speaking it is found that the most economical results are obtained when the capacity of the turbines is such as will enable them to be run at full load for about six months in the year.

By operating a steam plant in conjunction with the hydraulic installation, it becomes economically possible to increase the capacity of the hydraulic plant, the defect of its output at times of less than normal flow being made good by the steam installation. The latter also serves as a stand-by in case of a breakdown of the hydraulic plant. (*See* SUPER-POWER.) The best method of operation of such a combination depends upon the type of load, storage capacity, etc., and can only be determined by special reference to the special circumstances of each individual plant. Very often, however, the steam station is entrusted with the special duty of carrying the peak load. (A. H. GI.)

HYGIENE: *see* INDUSTRIAL WELFARE; PUBLIC HEALTH.

HYMANS, PAUL (1865–), Belgian politician, was born at Ixelles, Brussels, March 23 1865. He became a barrister in 1885, and from 1898 to 1914 was professor of comparative pa liamentary history at Brussels University. From 1900 he wa deputy for Brussels and soon became the Liberal leader. Aft a mission to President Wilson in Aug. 1914 he was plenipoten tiary in London, 1915–7, when he became head of the Ministr of Economic Affairs. From 1918–20 and 1924–5 he was Ministe for Foreign Affairs. In Nov. 1918 he attended the inter-Alli Council at Versailles; he also represented Belgium at the Pea Conference in 1919 and on her behalf signed the Peace Treat In the same capacity he attended the conferences at San Rem Boulogne, Brussels and Spa. He played a leading part in th settlement of the Ruhr question, the Dawes Plan, the Se curity Pact and the economic union of Luxembourg with Be gium. In Jan. 1920 he was appointed Belgian representati on the League of Nations, and in the same year was made pres dent of the first Assembly at Geneva. A member of the Académi Royale de Belgique, M. Hymans wrote *L'histoire parlementai de la Belgique* and *Frère Orban.*

HYNDMAN, HENRY MAYERS (1842–1921), British politicia was born March 7 1842 in London. His father was a barrist and founder of the Hyndman Trust for building churches. Aft leaving Trinity College, Cambridge, he travelled extensively a became war correspondent for *The Pall Mall Gazette* during th Austro-Prussian War of 1866. In 1881 he founded the Soci Democratic Federation and from this time on was the chi exponent of Marxism in Great Britain. As such, he came int conflict with William Morris and later with J. Ramsay MacDo ald. Hyndman opposed the South African War; took an activ part in the Second International; but, in spite of his sympathi with India's demand for self-government he took a strongl Imperialistic line at the outbreak of the World War in 1914. H died in London Nov. 22 1921. One of his latest books, *Th Evolution of Revolution* (1920), clearly sets out his general view in addition to numerous other propagandist works he also wro *Records of an Adventurous Life* (1911); *Further Reminiscen* (1912); and *The Future of Democracy* (1915). See Rosalind Hyndman, *The Last Years of H. M. Hyndman* (1923).

HYTHE, CONFERENCE OF (May 15 to 17 1920), a meeti between the British and French Prime Ministers, togeth with the Chancellor of the Exchequer and the French Minist of Finance, in preparation for the Conference of Spa (*see* S CONFERENCE OF). A French proposal that France should granted priority in reparation payments seems to have bee put forward but not pressed, and the linking up of the reparati problem with the question of inter-Allied debts was propose publicly for the first time in the official communiqué.

BÁÑEZ, VICENTE BLASCO (1867–), Spanish novelist and politician, was born at Valencia Jan. 29 1867. He became an impassioned political agitator and suffered exile, hard labour and frequent imprisonment for his opinions, although was returned to Parliament on eight occasions by his native y. His early novels, of which *Canas y Barro* is considered the t, deal with life in Valencia and are in some respects superior to later productions. Although a republican, Ibáñez held strong i-feminist opinions. He travelled extensively and achieved rld-wide success as a writer for the cinematograph. Among best-known novels are *La Catedral* (1903, English translation, *e Shadow of the Cathedral*, 1909); *Sangre y Arena* (1908, Eng- translation, *Blood and Sand*, 1913); *Los cuatro Jinetes del ocalipsis* (1916, English translation, *The Four Horsemen of Apocalypse*, 1918) and *Mare Nostrum* (1918, English transla- n, *Our Sea*, 1920). He was unpopular in Spain, where his tings were ignored by the majority, and he eventually settled Paris, becoming the centre of a group of politicians with i-monarchical views.

CELAND (*see* 14.227), an independent State in personal union h Denmark. Its area is 40,437 sq. m. and its population is out 100,000. In 1918 Iceland was recognised as a separate gdom, with unlimited sovereignty, in personal union with nmark. According to the Act of Union there are no real nt affairs; Denmark, however, provisionally till 1940, takes rge of the foreign affairs of Iceland as its mandatory. For same period Danish and Icelandic citizens, residing in either te, enjoy in every respect equal rights. Since 1915 Iceland had its own merchant flag; since 1918 its own national arms. road Danish legations act on behalf of both Denmark and land. Iceland has a legation in Denmark, and Denmark gation in Iceland; other states are represented in Iceland by nsulates.

onstitution.—According to Iceland's new constitution (1920) King shares the legislative power with the Parliament, the hing, an assembly of 42 members, sitting in two divisions, Upper House (14) and the Lower House (28), but in cases of sension it can assemble as a joint parliament. The Cabinet nsists of three ministers, but there is no governor-general, and ry legislative Act passed by the Althing and many admin- rative measures must be sent to the King in Copenhagen for nature. Since 1920 Iceland has had its own supreme court, l (since 1911) its own university. Other improvements in ucation are the establishment of a teachers' seminary and a stem of public schools. In almost every other respect Ice- d in this period has made constant and rapid progress.

Population.—The total population in 1925 was 100,000 01, 78,000), about 50% living in towns and trading-stations. ere are seven towns with chartered privileges, the greatest of ich is the capital *Reykjavik*, which has about 22,000 inhabi- nts (1901, 6,700).

Industry.—The fishing trade has been considerably improved the introduction of new methods, especially steam trawlers d motor cutters, and the export of fish products, chiefly cured lit cod, herring and fish oils increased from a value of 11,000,000 in 1911 to 68,000,000 kr. in 1924. The cultivation of the l is also constantly improving, though in a smaller degree, and iry farming after the Danish method has been introduced, by ich the production of butter has been greatly improved. With exception of several handicrafts in the towns there is almost industry. Some woollen factories have been established, and eld a good return, but capital is lacking to provide as many are needed.

Water Power.—In its innumerable waterfalls (the greatest d most accessible estimated to represent about 4,000,000 horse wer). Iceland is in possession of almost inexhaustible motive wer, and it is very likely that considerable industries may ow up in Iceland in the near future; both Danish and Norwegian companies during the War petitioned the Althing for concessions to utilise some of the greater falls. The realisation of this plan was, however, hindered partly by the Icelanders' reluctance owing to their fear of invasion of foreigners and partly by the common European economic crisis. Thus far the water power has only been used to produce electric light in most of the towns and on some few farms.

Minerals.—The only mining industry is that of the precious calcareous spar, only found in Iceland, as the many rich sulphur mines and the lignite mines, worked during the War cannot pay on account of difficult transport to the coast. Both iron and copper and even gold have been found, and English as well as German experts have declared that the working of the gold mines near Reykjavik would be remunerative; here a German-Dutch Company was still engaged in preparatory investigations in 1925.

Communications.—Communications are constantly developing, and driving roads have been made in almost every district; bridges have also been constructed over most of the rivers, and a scheme for construction of a railway was in 1925 fully prepared by the Government. A telegraph cable to Shetland was opened in 1906, and telegraph and telephone lines inland have been extended practically throughout the whole country. In 1917 a wireless telegraph station was erected in Reykjavik and broadcasting (radio) introduced in 1925. The lighthouse system is yearly improving, and at Reykjavik a modern harbour with quays and cranes has been built. In 1914 Iceland acquired its own steamship company, which in 1925 controlled six mail steamers.

Public Health.—The birth-rate in 1923 was 26·5 per 1,000 and the death-rate 12·5 per 1,000, the latter showing a marked improvement on pre-war figures. A mental hospital and a sanatorium for tuberculosis, together with some other minor infirmaries, have been established and the building of a great state hospital in Reykjavik was commenced in 1925.

Liquor Control.—From 1912 onwards there came into force a system of complete prohibition of import and making of any liquor containing more than 2¼ % of alcohol, with the exception of medical requirements and denaturalised spirits for industrial use. But in 1923 Spain (the chief market for Iceland's fish products) forced Iceland to allow import and sale of Spanish wines, while the prohibition for the rest has been maintained.

(V. G.)

ICELANDIC LITERATURE (*see* 14.240).—As in the previous period poetry takes the foremost place; although great progress was made in novel writing, and the drama also gained in significance. Among the many lyrical poets Einar Benediktsson and St. G. Stephanson, resident in Canada, were the most important, both rather heavy in style, but rich in ideas and weighty in thought. Lighter and more elegant in style are Davíd Stefánsson, Stefán frá Hvítadal and Hulda (pseudonym Unnur Bjarklind), while the best novelists are Einar H. Kvaran and Gunnar Gunnarsson. Gudmundur Fridjónsson, Jón Trausti (pseudonym Gudmundur Magnússon) and Gudm. G. Hagalínre portray folk life with considerable skill; so do J. M. Bjarnason and Laura Salverson; both reside in Canada and portray the life of the Icelandic colonists there, the latter writing in English, *e.g.*, *The Viking Heart*. The best dramatists are Jóhann Sigurjónsson and Gudm. Kamban, whose dramas achieved a great success at the Royal Theatre in Copenhagen. The drama, *The Mother-in Law*, by an Icelandic countrywoman, Kristín Sigfúsdottir, was produced at Reykjavík and Winnipeg, and was much admired.

Among the more notable writers on other subjects were, Tón Adlis, Páll E. Olason and Jon Helgason on history, J. Th. Thoroddsen on geography, and Sigfus Sigfússon on folklore. Sigfús Blöndal published an Icelandic-Danish Dictionary, the first complete dictionary of modern Icelandic.

BIBLIOGRAPHY.—Halldór Hermannsson, *Islandica*, vol. 6, 16 vol. (1908–24); *Icelandic Authors of To-day* (1913); Sigurdur Nordal, *Islenzk Lestrarbok* (1924); Edmund Gosse and W. A. Craigie, *The Oxford Book of Scandinavian Verse*, p. 331–423 (1925).

IDAHO (*see* 14.276).—The population in 1920 was 431,866, of which the rural population, 312,829 constituted 72·4%. The total population in 1926 was estimated by the Bureau of the Census at 522,175. The average number of inhabitants per sq. m. increased from 3·9 in 1910 to 5·2 in 1920. Boise, the capital and largest city, had in 1920 a population of 21,393 (17,358 in 1910).

Agriculture.—Agriculture continues to be the principal source of wealth. In 1925 the number of farms was 40,582 as compared with 42,106 in 1920 and 30,807 in 1910. Nearly two-fifths of all the farms were between 100 and 174 acres. The average value of land and buildings per farm in 1925 was $9,213 as compared with $313,811 in 1920 and $7,955 in 1910. The number of mortgaged farms nearly doubled in the 10 years 1910–20. The farm value of all crops in 1923 was $81,308,000 as compared with an average value for the period 1917–21 of $106,209,000. The following table indicates the statistical position of several of the more important crops for the year 1924:—

Crop	Acreage	Production	Farm value
Oats . . .	184,000	6,624,000 bu.	$ 3,842,000
Barley . . .	162,000	2,958,000 bu.	2,426,000
Wheat . . .	933,000	17,828,000 bu.	23,355,000
Hay . . .	1,018,000	2,059,000 tons	25,120,000
Potatoes . . .	67,000	10,725,000 bu.	5,792,000

Specialised cash-crop agriculture is replacing the older type of farming. Because of transportation costs on bulky products, more attention is being given to seed production, beans, peas, head lettuce and the like. Dairying is of increasing importance, much of the output being marketed in the form of cheese. As a sheep-producing state, Idaho ranked fourth in 1924 with nearly 2·05 million head having an estimated farm value of 22 million dollars. The total value of all livestock on Idaho farms was estimated at $49,000,000, in 1924. Poultry production for the Pacific Coast market is rapidly becoming a leading agricultural enterprise. About half the farms in the state were under irrigation in 1920. The enlarged American Falls Dam, which was in 1925 the largest Federal reclamation project, was undertaken to provide additional storage capacity for the existing irrigated areas of southern Idaho.

Mining.—Mining continues to rank second in economic importance. The following table shows the value of mineral production since 1920:—

	Gold	Silver	Lead	Copper	Zinc
1920	$459,000	$8,379,000	$22,292,000	$ 491,000	$1,785,000
1921	552,000	6,184,000	9,559,000	172,000	94,000
1922	458,000	6,149,000	11,762,000	394,000	431,000
1923	733,000	6,158,000	18,550,000	2,292,000	603,000

Lead is first in importance, the principal mines being in the Coeur d'Alene district. Successful developments of lead-silver and lead-zinc ores have been made in the east central part of the state, largely stimulated by the mining activities of the Ford Motor Co. The extraction of silver is in most sections incidental to lead mining. In recent years there has been a renewed exploitation of zinc ores. The Interstate-Callahan Mine is probably the third largest producer of zinc ore in the United States. The largest copper-producing area is in Custer county. The Seven Devils range in Adams county is one of the most extensively mineralised copper belts in the west. Tungsten mines are being developed in Lemhi county. In southwestern Idaho are great quantities of phosphate rock which are being gradually exploited.

Manufactures.—There has been a marked growth since 1910 both in the number of manufacturing establishments and in the value of their products. The following are the chief industries, in order of importance: lumber, flour and grist mills, car and railway shops, printing and publishing. About half of the value of all manufactured goods is represented by lumber products. Idaho ranks first among the states in the area of state and national forests, aggregating approximately 19 million acres. In addition there are large stretches of privately owned timber land.

Transport.—In 1923 the state had 2,877 m. of steam railway and 89 m. of electric track. In 1915 the Celilo Canal, on the Oregon side of the Columbia river, was opened and vessels c
now pass from the Pacific to Lewiston, a distance of 480 mil

Government.—The legislature of 1919 completely re-organis
the state civil administration in so far as the limitations impos
by the state constitution permitted. The Administrative Co
solidation Act abolished some 46 boards, commissions and
fices and gave Idaho a consolidated form of state government,
as it is locally called, a cabinet or commission form of gover
ment, with the governor at the head, assisted by nine depa
mental commissioners. These nine departments are: Agricultu
Commerce and Industry; Finance; Immigration; Law Enforc
ment; Public Investment; Public Welfare; Public Work
Reclamation. Each commissioner is appointed by the govern
and, except "those under the constitution who are appointed
specific terms," may be removed by him at his discretion.
certain departments a small number of designated officers a
appointed by the governor, but on the whole the organisati
within each department is under the control of the commission
This consolidated form of government concentrates authority
the hands of the governor to a marked degree. The law provid
an executive budget system for the state. The Eighteenth (Pr
hibition) Federal Amendment was ratified Jan. 8 1919.

Education.—In 1924–5 there were 137,256 pupils enrolled
the state schools, of whom 19,759 were in the high schools a
117,497 in the elementary schools. The state university co
prises colleges of Letters and Sciences, Agriculture, Engineeri
and Law; schools of Forestry, Mines, Education, Business A
ministration and Graduate Study. The total enrolment in 19
was over 2,000. Idaho has attracted much attention because
its scientific and economical administration of higher educati
A Board of Education of five members appointed by the gove
nor for terms of five years, has general supervision over the n
mal schools and the Technical Institute, and, as a Board of R
gents, over the university as well. The result is a unified syst
of higher education with little duplication, low cost and exc
lent standard.

The governors during the period 1910–25 were: James
Brady, Rep., 1909–11; James H. Hawley, Dem., 1911–3; Jo
M. Haines, Rep., 1913–5; Moses Alexander, Dem., 1915–9; D.
Davis, Rep., 1919–23; C. C. Moore, Rep., 1923–

Administration; and the *Forestry Bulletin* issued by the School
Forestry at the State university. (H. C. D.

ILLEGITIMACY (*see* 14.301).—Illegitimacy may be measur
in different ways. One way is to state the number of illegitima
births in every 1,000 births as in Table I. The range of variati
there shown between different countries is much more striki
than the variation between different times in the same countr
Where the figures are small they may be incomplete. Statisti
are not given for the United States as a whole; in New York t
rate is in the neighbourhood of 12, and in Pennsylvania,
In countries affected by the War the rates were generally highe
during the War period; thus, in Germany, the rates in the perio
1911–4, 1915–8, 1919–22 were 94, 115, 109; in Hungary, th
were 90, 104, 76; in France, 87, 132, 132 (the last for 1919 onl
Taking the rates as recorded, two causes might account for this:
might be due to a rise in the number of illegitimate births, or,
in this country, chiefly to a fall in the total number of birt
the second movement sometimes disguises the other. But
must be borne in mind that the figures for successive periods a
not really comparable for countries with altered territories.

A better method of measurement is to refer illegitimate bir
to the total of unmarried women at fertile ages. Thus, from t
date when the decline of the birth-rate in England began, ab
1876–80, to 1919–23, the number of legitimate births, per 1,
married women between the ages of 15 and 45, had fallen 44
the number of illegitimate births, per 1,000 single and widow
women between the same ages, had fallen 46%; while the num
of illegitimate births per 1,000 of all births had only fallen ab

o per cent. Table II. shows the illegitimate rates, calculated by is better method, in a few countries for which data are avail-le in a pre-war and a post-war period. The trend, though some cases slight, is downward, and we know that the same nd was apparent in earlier years. This does not necessarily ply a rise in the standard of morality: it may denote an in-easing use of means to prevent conception.

In Table III. the number of illegitimate births in England and ales in 1921, expressed per 1,000 of the total census population, is alysed according to locality and according to extent of urbanisa-n. The third column shows these rates as percentages of the rate the country as a whole. The last column represents an attempt the registrar-general to allow for the number of potential mothers nong the unmarried at different ages between 15 and 45 in each ality or class of area; for this purpose certain standard fertility es applicable to different age-groups are used, and the actual ths are compared with the "expected" births. The rates are her in Wales and the northern counties than in the southern and dland counties. The more accurate index also emphasises the hness of the rate in rural districts. These differences are in part e probably to differing degrees of familiarity with the use of con-ceptive measures. (*See* POPULATION.)

TABLE I. *Mean Number of Illegitimate Births per 1,000 of all Births, excluding Stillborn*

Country	1911–4	1915–8	1919–22	1923	1924

(D. C. J.)

ILLINOIS (*see* 14.304).—The population of Illinois according to the U.S. Census of 1920 was 6,485,280, as compared with 5,638,591 in 1910 and 4,821,550 in 1900. The rate of increase 1910–20 was 15% as against 14·9% for the whole United States and as against 16·9% for the state in the preceding decade. The population as of July 1 1926 was estimated to be 7,202,983. The increase of 1910–20 was urban, the rural population continuing to decline. In 1920 the percentage of urban population in towns and cities of 2,500 or over was 67·9% and 41·7% of the total population lived in the city of Chicago. In 1920, 52·5% of the state's population was in cities greater than 25,000. Population in villages of less than 2,500 declined from 12% in 1910 to 10·5% in 1920. Purely rural population fell from 26·4% in 1910 to 21·6% in 1920.

Population of Cities of over 40,000

City	Population 1910	Population 1920	Increase %	Estimate 1925
Chicago	2,185,283	2,701,705	23·6	2,995,239
Cicero	14,557	44,995	209·1	62,238
Decatur	31,140	43,818	40·7	50,359
East St. Louis	58,547	66,767	14·0	71,423
Peoria	66,950	76,121	13·7	81,564
Rockford	45,401	65,651	44·6	76,462
Springfield	51,678	59,183	14·5	63,923

Agriculture.—While the census of manufactures shows Illinois to be an industrial rather than an agricultural state, there has been no absolute decline in her agriculture. According to the census of 1920 Illinois was second only to Iowa among the states in agricultural importance. Based on crop values, in 1923, Texas was first, Iowa second, and Illinois third, with farm crops amounting to $459,509,000. Cereals are still the main crop and maize is the leading cereal. The largest crop was that of 1917 when 418,000,000 bu. were produced from 11,000,000 acres. In 1923 the crop of 337,000,000 bu. was a slight increase over the years immediately preceding. In 1923, 62,506,000 bu. of wheat were produced, grown on 3,479,000 acres. The production of oats has declined, but in 1923 with a harvest of 135,100,000 bu. from 3,860,000 ac. she took third place in the United States. In 1923 Illinois ranked seventh in the production of barley and rye, producing 3·33% of the barley and 5·56% of the rye grown in the United States. In livestock, Illinois, Jan. 1 1923, with 1,125,000 milch cows, ranked fourth among the States; and in other cattle, numbering 1,477,000, ranked sixth. In number of swine, 4,460,000 and the number of horses, 1,277,000, Illinois ranked second only to Iowa.

Manufactures.—In the value of manufactures, Illinois, in 1923, ranked fourth among the States. In 1919 the total value of her manufactured products was $3,366,452,969. In 1923 the total value had risen to $5,041,519,455. Manufactures employed 645,433 wage-earners, working in 14,348 establishments. The ten most important industries with the values of their respective products in that year are as follows:—

Manufactured Products, Illinois, 1923

Slaughtering and meat packing (wholesale)	$606,320,553
Foundry and machine shops	275,955,047
Iron and steel, steel works and rolling mills	213,671,552
Electrical machinery and supplies	211,366,206
Clothing, men's	186,683,333
Cars, steam road (not back in repair shop)	159,364,227
Printing and publishing, book and job	138,227,215
Printing, publishing, newpaper, etc.	132,288,355
Cars, and general construction, steam	113,604,362
Bread, and other bakery products	105,289,516

The tendency in manufacturing was toward large-scale production and corporate ownership Of the 18,593 establishments in the state in 1919, the 799 producing $1,000,000 or over turned out some 75% of the products. In these industries 389,686 wage-earners were employed. Chicago, with its tributary manufacturing suburbs of Maywood, Harvey, Cicero, Blue Island, Chicago Heights, and, in Indiana, Hammond and Gary, is the greatest manufacturing centre of the state. A lesser manufacturing centre has grown up in the net of railways that centre at St. Louis, Collinsville, Granite City and Edwardsville. The third centre is formed by Moline and Rock Island with Davenport, Iowa. Joliet and East St. Louis were second and third respectively to Chicago in the value of products in 1919. Manufactures in Chicago, are generally diversified. The same is usually true in the smaller centres, although a few cities are noted for their special products. Thus, Rockford is best known for its furniture manufactures, Kewanee for boilers, Elgin for watches, Moline for farm implements and automobiles.

Minerals.—In mining and allied interests Illinois occupies an important position. Coal constitutes her leading production. During 1924 67,880,000 short tons were mined, a total exceeded only by Pennsylvania and by West Virginia. The value of her petroleum production in that year was$14,200,000. Limestone, sandstone, fluorspar, lead and zinc are the other leading products.

Communications.—For transportation, Illinois relies chiefly on its steam railways. With 12,046 m. of main line she was in 1924 second only to Texas. For over 30 years little new main-line road has been built. The important extension has been in double-tracking and improvement of the right-of-way and terminals. The field of passenger and light freight and coal transport, since 1900, has been invaded by the electric lines, which by 1924 operated 3,555 m. of track. The Illinois Traction System operates a ramification of electric lines across the state from Danville to East St. Louis and radiating throughout central Illinois; on certain runs it operates sleeping and parlour cars. Illinois' most important water transportation system is that of the Great Lakes. Receipts of grain at Chicago by lake have steadily declined of late years, although the lakes are still the usual route for shipment of wheat to eastern points. Flour shipments by lake are comparatively insignificant, an important fact in view of the increasing quantity of grain milled at Chicago. Iron ore is still shipped to Chicago and South Chicago by way of the Great Lakes. In 1900 the Sanitary District Channel was opened, providing a waterway with a depth of 20 ft. for navigation between Chicago and Lockport. But from Lockport to Utica, on the Illinois river, a distance of 62 m., there was no adequate means of water transportation. A legislative Act of 1919 actively supported by Gov. Frank O. Lowden provided for the issue of bonds to the amount of $20,000,000 for the construction of an eight-foot channel, "The Illinois Waterway," connecting the points mentioned. Little actual progress had up to 1925 been made towards carrying out this project for the Lakes-to-the-Gulf water route.

The improvement of the roads in the state of Illinois has in recent years been given marked attention. A state highway commission was created in 1905, various laws facilitating local road improvement were passed, and in 1914 state appropriations for hard roads were made from the proceeds of automobile licence fees. Actual construction was begun in 1914. Acts of Congress of 1916 and 1919, apportioning Federal aid in behalf of roads, allotted to Illinois $3,300,000 and $8,700,000 respectively. The question of issuing $60,000,000 in bonds based on automobile license fees for the construction of 4,800 m. of hard roads was submitted to the voters of the state in Nov. 1918 and was approved by them. Construction of roads under Federal aid and by means of this bond issue has been going forward. In 1922 722 m. were completed and over 1,000 m. in 1923. The state Legislature in 1923 authorised a bond issue of $100,000,000, providing for the continuance of a state-wide system of hard-surface roads, and this legislation was approved by the people at the General Election of 1924.

Banking.—The northern part of Illinois lies in the 7th Federal Reserve District and the southern part in the 8th, with headquarters respectively in Chicago and St. Louis. In 1925 there were 501 National banks in Illinois with aggregate capital stock of $94,480,000, aggregate surplus of $63,265,000 and total resources of $1,701,448,000. Of these banks 32 are located in Chicago, having resources amounting to $1,103,339,000. Side by side with the National banks is the system of state banks created by the Act of 1887, and operating under the supervision of the Auditor of Public Accounts. In 1925 there were 1,396
state banks with a total capital of $160,240,000, and aggreg
resources of $2,682,196,000. Of the state banks 176 are in C
cago, having resources amounting to $1,926,594,000.

Government.—Despite the difficulty of changing the orga
law, in the period 1910–25 there were far-reaching changes in
organisation of the machinery for government. Under the co
stitution of 1870 an amendment must be initiated by two-thi
of both Houses in the General Assembly and approved by
majority of all persons voting at the next election. Further, in
session an amendment to but one article can be proposed, and
two amendments to any article can be offered within four yea
Revision of the constitution by amendment, therefore, prov
too difficult, and in 1917 the General Assembly voted to subm
to the people the question of a constitutional convention, whi
was approved at the election of Nov. 1918. Accordingly, in 19
an Act was passed for a convention to meet Jan. 6 1920. D
ficulties arose over Chicago's representation in the Gene
Assembly, and in Dec. 1920 the convention adjourned with
work unfinished to meet in Sept. 1921. Sessions were held
intervals until June 28 1922 when the constitution was adopt
for submission to the people for ratification at a special electi
to be held Sept. 12. The new constitution, in this election, w
defeated by a decisive majority.

Changes in the state's system of appointments have be
effected. First, in time, was the extension, by the Act of 1911,
the civil-service system, to the greater part of the state's e
ployees. Civil service now covers all state appointees, exc
those appointed by the governor and confirmed by the Senat
the scientific and academic staff of the University of Illinois a
the normal schools, and a few others. All examinations are co
petitive, although for some scientific posts "unassembled e
aminations" are given which consist of questions as to traini
and experience. By an amendment of 1917 all appointees m
be removed by the appointing authority, but are allowed
appeal to the state Civil Service Commission on allegation th
the removal is due to race, politics or religion. Reorganisat
of governmental machinery was begun in 1909 with the aboliti
of separate boards for the various state charitable instituti
and the establishment of one central board of control possessi
also certain powers over private charitable institutions. In ad
tion to this board a supervisory state charities commission w
created. There remained, however, over one hundred st
boards, bureaus and offices, paid and unpaid, created to execu
various acts and to supervise various state institutions. Th
result was disorder and waste. A reorganisation recommend
by a committee in 1914 was in great part adopted in the Sta
Consolidation Act of 1917. This Act necessarily left untouch
the constitutional offices, secretary of state, auditor of pub
accounts, treasurer, attorney-general and superintendent
public instruction, but set up in addition to them nine depar
ments—Finance, Agriculture, Labor, Mines and Miner
Public Works and Buildings, Public Welfare, Public Heal
Trade and Commerce, Registration and Education. The he
of these various departments, who are appointed by the govern
and Senate, have acted as a Cabinet for the governor. Illino
ratified the Eighteenth (Prohibition) Federal constitution
amendment Jan. 14 1910.

Public Finance.—Expenditures authorised by the Legislatu
for the biennium 1925–7 amounted to nearly $300,000,000.
the appropriations for 1925–7, $131,000,000 was for the co
tinuance of the hard-roads plan. It was anticipated that $
000,000 of this amount would be supplied from money receiv
by the state for automobile licences, while the remainder wou
come from the sale of $100,000,000 in bonds, the issue of whi
was approved by the people at the Nov. election of 1924. Amo
other more important items of appropriation were: Pub
Welfare Dept. including state charitable, penal and reformato
institutions, $28,979,000; omnibus bill, $23,718,000; sta
treasurer, retirement of and interest on bonds, $23,575,00
public schools, $16,223,000; University of Illinois, $10,620,0
state normal schools, five in number, $3,150,000; Agricultur
Dept. $2,691,000; Health Department, $1,041,000.

lucation.—In 1924 there were enrolled in the elementary ols of Illinois 563,614 boys and 534,684 girls. In the state schools there were 106,735 boys and 111,005 girls. This esents an increase of 113·76% in the number of high school ls during a period of ten years. In addition to the public ols there were, in 1924, 960 private schools with 195,552 ls. The total number of teachers in the elementary schools)24 was 42,865. In that year there were 9,117 high school hers. The net expenditure, including new grounds and lings and payments of bonded indebtedness with interest 922 was $103,375,359. Of this amount, $79,126,323 was t on current expenses, $20,386,043 for new grounds, build- and equipment, $2,224,466 for cancellation of bonded btedness, and $1,638,627 for interest on bonds. The salaries to teachers were comparatively low. The average salary nen was $1,679; for women, $1,449. A notable development ie public educational system was the growth in the number ownship high schools, and the number of community high ols following the legislation of 1917. Under the township -school law some 200 high schools were organised. Acts of ; and 1915 directed the payment by local school authorities uition for children who wished to attend high school elsere when there was none in their district. During one year,), 167 community high schools were organised, and at the of 1922 there were 465 such schools in the state. At the close he year 1924 the number had risen to 915. With the rapid vth in the numbers of high school graduates (24,507 in 1924) e was a corresponding increase in the enrolment in the uniities and colleges of the state. The attendance at the versity of Chicago, 1923–4, was 13,357; University of Illinois 83; and Northwestern University, 9,150. In addition, there in the state 29 colleges of recognised standing and 6 teachers' ges. Located in Chicago are four Class A medical schools, Class A law schools, three Class A dental schools and nine ools of theology.

ecent Political History.—In 1912, as a result of the Progres- secession, the Republican party for the first time in 16 years control of the state, the Democratic presidential elector ning by a vote of 405,038, as against 386,478 for the Pro- sives and 253,593 for the Republicans. The Democratic e ticket headed by Edward F. Dunne was elected by a somet larger plurality over Gov. Charles S. Deneen, Republican, Frank H. Funk, Progressive. The Democrats, however, did control the General Assembly on joint ballot, and had to promise with the Republicans on the election of one Demo- ic Senator, James Hamilton Lewis, and one Republican, vrence Y. Sherman, the latter to fill an unexpired term to 5. By 1914 the normal Republican majority in the state sserted itself, the popular vote for Senator in that year being Y. Sherman, Republican, 390,661; Roger Sullivan, Democrat, ,403; Raymond Robins, Progressive, 203,027. President odrow Wilson lost the state in the presidential election of 6 by 160,000 votes. Frank O. Lowden, Republican, was ted governor over Edward F. Dunne.

n spite of the appeal for the support of the administration of odrow Wilson which was made on patriotic grounds, only five mocratic Congressmen were elected by the state in 1918, and dill McCormick, Republican, defeated J. H. Lewis, Demo- t, for Senator by 53,024 votes. In 1920, after an extremely ter primary fight in the Republican party, Len Small was minated for the governorship over John J. Oglesby. In the ction, Republican state and national tickets swept the state overwhelming majorities. In the primary election for gover- , April 8 1924, Gov. Len Small received a plurality of 920 votes over Thurlow G. Essington, and Norman L. Jones s nominated by the Democratic party. Charles S. Deneen eated Senator Medill McCormick for nomination for the S. Senate on the Republican ticket. Governor Small made his npaign chiefly on his record for the promotion of the construc- n of hard roads. The road-bond issue of $100,000,000 for s purpose was voted on at the same time. Gov. Small was elected with a plurality of 345,028 votes over the Democratic nominee. Deneen was elected to the U.S. Senate. The governors of Illinois after 1905 were: Charles S. Deneen, Rep., 1905–13; Edward F. Dunne, Dem., 1913–7; Frank O. Lowden, Rep., 1917–21; Len Small, Rep., 1921–5, and 1925– .

See, in addition to the books listed in 14.311, *Centennial History of Illinois* (5 vol., published by the state, 1918–20) and later volumes of the *Illinois Historical Collections.* (J. A. J.)

ILLUMINATING ENGINEERING, term now used to denote all applications of natural and artificial light in the service of mankind. Progress in Great Britain since 1910 is largely the result of the formation (in 1909) of the Illuminating Engineering Society, in which makers of lamps and lighting appliances and users of light co-operate; all illuminants are represented and all aspects of the subject, economic, hygienic and artistic are considered. A similar body, the pioneer in this field, has been in existence in the United States since 1906, and corresponding bodies have been formed in Germany (1913), Austria and Hungary (1925) and Japan (1915). In Germany two additional societies operating in Karlsruhe and in the Rhine-Westphalia district have also been created.

Attention has been paid to illumination at many international congresses, thus promoting the exchange of views between experts in different countries. The re-organisation of the international photometric commission, founded in 1900, as the international illumination commission, was stopped by the World War, but a fresh start was made in 1921, and the leading countries are now represented with national committees for the respective countries.[1]

Much has been done towards standardisation and agreement on common principles. Definitions of the main photometric quantities have been adopted, and a more extended series of definitions, symbols, etc., framed, while sub-committees to deal with lighting legislation, automobile headlights, etc., have been formed. At the session held in Geneva in 1924 further activities were initiated and the Commission is now extending its work to deal with various practical problems.

The International Candle.—A noteworthy step, dating from 1909, has been the agreement between France, the United States and Great Britain and, recently, also Russia, on an international candle so that the same unit of light is now in use in all four countries; but in Germany and some other countries the Hefner candle (equal to 0·9 international candle) is still in use. Preservation of the unit of light is now effected by the exchange of specially prepared electric lamp-standards between the official laboratories in the countries concerned. Meantime experiments are being made with a view to evolving an absolute standard of light, *e.g.*, one based on the maintenance of a "black body" at a specified temperature. In the United States the standard is the *lumen* or the amount of light that would fall on a surface so placed that all its parts are at a distance of one foot from a light source of one candle power.

Technical Progress.—Progress in illuminants has kept pace with this advance on the scientific side. Electric lamps, filament and arc, have been developed (*see* ELECTRIC LIGHTING). In the field of gas lighting there has been steady progress in design, one instance being the smaller and more compact forms of high-pressure gas lamps, now rated to give 60 candles per cu. ft. of gas consumed. In low-pressure gas lighting the use of superheated clusters of inverted mantles has made possible a gain in efficiency estimated at 30%. The distribution of the light from a number of smaller mantles is considered an advantage, and the smaller types of mantles are the most durable. Cluster-lamps giving up to 2,000 c.p. are now available.

Theory of Radiation.—Researches into the theory of radiation and the principles underlying illuminants provide a clearer understanding of the luminous efficiency theoretically obtainable. Thus a light source yielding visible white light and no non-luminous vibrations would operate at approximately 26 c.p. per watt, whilst if the light were confined to the most efficient yellow-green section of the spectrum as much as 60 c.p. per watt might be obtained. But in the case of new illuminants efficiency is not the only consideration; such special qualities as the colour of the light (as in the neon lamps) or the nature of the supplementary invisible radiation (as in the quartz tube mercury vapour lamps) may be of even greater importance.

---

[1] See J. W. T. Walsh, "International Co-ordination in Illumination," *Trans. First World Power Congress,* vol. 3 (Wembley, 1924).

Reflectors, etc.—The design of shades, globes and reflectors for use with lamps has assumed great importance. By suitable design of a reflector the distribution of light from a source may be altered with wide limits. Thus extensive, intensive and focusing forms of reflectors yielding standard curves of light distribution have been designed, and corresponding rules for height and spacing, designed to give even illumination on the working plane have been derived. In most cases a shade or reflector is designed to direct most of the light downwards, where it is chiefly needed. But other cases occur, for example in shop window lighting and the illumination of large posters, etc., where reflectors are so designed and spaced as to yield an illumination over an extensive vertical area.

Glare Prevention.—Another function of shades and reflectors is to screen the actual source of light from the eye. Even when only vacuum metal filament electric lamps were available the glare from exposed filaments irritated the eye and prevented it from registering the full effect of the illumination provided. In the case of the gas-filled lamps, with their very much brighter filaments, the need for scientific screening is yet more evident. Hence in the leading stores concealed lighting of show-windows, with the light thrown on the goods but the sources concealed from the eyes of observers, is coming to be regarded as the correct method; and it is only in the smaller shops that exposed sources of light are still too frequent.

A special instance of a concentrating reflector is to be found in the " floodlighting " units, consisting of an incandescent lamp with a special " bunched " filament at the focus of a parabolic mirror. Such units are miniature searchlights and are now being used to illuminate the façades of buildings. It is possible to limit the angle of dispersion to about 15° and with a 500 watt lamp a beam with a candle power exceeding 300,000 has been obtained. With the searchlight proper, using an arc, the dimensions of the source of light can be reduced to much smaller dimensions, and a beam of many millions of candle power attained.

Searchlights.—A notable advance during the War was the design of searchlights using specially cooled electrodes leading to a yet smaller and more brilliant source and corresponding greater concentration. The cooling has been effected by two distinct methods, a blast of air and a spray of alcohol; in both cases a very substantial increase in beam-candle power for a given current consumption was obtained.[1] The brightness of the crater in such cases has been estimated at 200,000–300,000 candles per sq. in., as compared with 85,000 c.p. per sq. in., in the case of the ordinary searchlight. In Germany, Lummer, working with an arc operating in a chamber under an air-pressure of 22 atmospheres, is said to have attained the enormous brightness of 1,500,000 candles per sq. in. But this method has apparently not yet reached a practical stage.[2]

Coloured Light.—An apparatus capable of projecting pure spectrum colours on the stage, which is in effect a giant spectroscope, has been designed. By the Mutochrome projector,[3] a series of superimposed patterns can be projected on the screen and the colour of each varied at will. This is likely to prove of considerable value to designers of wallpapers and coloured fabrics, as well as having a possible application for the projection of luminous scenery on the stage.

Artificial Daylight.—Efforts have also been made to provide " artificial daylight," *i.e.*, to correct the light from artificial illuminants and render it equivalent to normal daylight for the matching of colours. Two methods of effecting this correction have been applied. In the Sheringham unit the light from a gas-filled lamp is reflected from an upper surface coated with a pattern of
green, blue and a small amount of yellow in suitable proporti
In the system usually associated with the name of Mr. F.
Lamplough, the light is filtered through a combination of tin
glass. In either case the efficiency of the apparatus is necessa
low, 60% or more of the original light being lost in making
correction. But the advantage to firms in the dyeing indus
and others concerned with delicate colour-matching of hav
an invariable artificial light, independent of the wide variati
of natural daylight, is very considerable.

Industrial Applications.—The problems of the lighting
streets, schools, factories, shops, etc., of the avoidance of
strain in cinema theatres and the importance assigned to pro
lighting in factories, the interests of health, safety and efficie
of work, have been investigated by the Illuminating Engineer
Society and Home Office Committees.[4] Evidence on light
requirements in factories has been collected from many differ
sources, and records of over 4,000 tests of illumination in dif
ent factories have been presented. The minimum values
illumination in the interests of safety (0·25—0·4 ft.c.) are
tablished. Recommendations on the subject of avoidance
glare, flickers and inconvenient shadows have been made,
the illumination required for carrying out work done is shown t
not less than three foot-candles for fine work and five foot-c
dles for very fine work. Consultations with various joint indust
councils are now proceeding with a view to determining w
constitutes suitable and adequate lighting for processes in th
respective industries.

Progress in the United States.—In the United States detai
codes of industrial lighting have been adopted in seven differ
states. In principle these follow closely the recommendations
the British Committee. Methods of grading various light
units according to the degree of " glare " are outlined, and
positions which may safely be assigned to such units in a wo
shop are tabulated. The codes also contain standards of
illumination requisite for various processes, a distinction be
drawn in the most recent codes between the minimum va
desirable and higher values recommended in the interests
economic production. A considerable amount of research
been devoted to the relation between conditions of illuminati
and efficiency of work. Thus it has been shown by Dr. Ives
the United States Public Health Service that the dispatchi
service in post offices was expedited and rendered more accura
by better conditions of illumination;[5] tests in laboratories
Germany have likewise revealed a close connection betwe
illumination and many processes involving exact vision a
manual dexterity.[6] The subject of industrial lighting has lik
wise been studied by the International Labour Bureau of t
League of Nations in Geneva.

Particularly difficult cases of industrial lighting also form t
subject of study by the committee on illumination, worki
under the department for scientific and industrial research.
which eminent architects and medical men, besides lighti
experts, are represented. This committee also deals with
inquiries bearing on illumination received from the various go
ernment departments. In connection with this and other aspe
of lighting, increased attention is now being devoted to the h
gienic side, and at the international congress for the study
industrial hygiene held in Geneva in 1924 a special resoluti
was passed accepting good illumination as of equal importan
with heating, ventilation and sanitary conditions, in the interes
of health and safety.

Standardisation.—Standardisation in various fields is bei
dealt with by various sub-committees, working under the Briti
Engineering Standards Association, which have prepared spe
fications on the performance and dimensions of electric lam
and have also recently issued standard specifications for porta

nation photometers[1] and reflectors used for industrial light-)ther subjects now being dealt with include lighting glass- . and the illumination of schools, offices and streets.

ffic and Lighting.—Experience during recent years has ı that the questions of lighting and transport are closely d. With the progressive increase in the volume of fast- ı motor-traffic the necessity for good public lighting has ıe even more urgent than in the past; and the increase in umber of street accidents year by year has drawn public tion to the importance of the question. A new problem sented by the lighting of arterial roads connecting cities. routes are primarily intended for fast motor traffic and utility will not be fully realised unless adequate artificial ng is provided, enabling them to be used with safety by as well as by day. Special methods of illuminating such s are now the subject of consideration.

ny devices eliminating glare from powerful automobile ights have been suggested, some of the most promising on the limitation of the main portion of the beam below a n horizontal plane so as to avoid the direction of rays into yes of approaching drivers or pedestrians. But the most ul solution lies in the provision of better public lighting, ı would render very powerful headlights unnecessary.

ɔgress in these various directions has been aided very greatly e introduction of simple forms of instruments for measuring ination, of which quite a variety of types are now available. information acquired in this way has been very helpful in ng recommendations for the degree of illumination neces- for various purposes.

Walsh, *Elementary Principles of Lighting and metry* (1923); see also *The Illuminating Engineer* (The al of Good Lighting), official organ of the Illuminating Engi- ıg Society; *The Transactions of the Illuminating Engineering y in the United States;* and *Licht und Lampe* (Official organof the inating Engineering Society in Germany). (L. G.*)

USTRATION (*see* 14.321).—By 1910 the rapid advance in arious methods of process reproduction had resulted in the lete liberation of the draughtsman from any of those con- ıtions which had limited him in the days of the reproductive -engravers. This new freedom was in some ways a misfor- especially as photography made it possible to reduce a n to any convenient size, so that the artist too often forgot ether that his object was to decorate a book. The perfect rator is rare, and the most admirable drawings, when are merely attached to an author's text, may not be illus- ons at all.

e new interest in typography, stimulated by the work of am Morris, but in reaction against the heaviness of his , has resulted during the decade 1915–25 in an enormous ase in the number of beautifully printed books issued from ress. Many of the English editors content themselves with ypography, embellished perhaps with occasional head pieces *uls-de-lampe*, but most of these decorative details are well- ived, and pleasantly arranged with reference to the size of age and the area of the type.

e possibilities of the woodcut have been most fully appre- d and exploited on the European continent. Its advantage the intaglio methods, such as etching or copper-engraving, is the wood block can be printed with the type by a single tion. Technically, however, it is a reaction, and the small- of its field makes it unsuitable for use in illustrating popular zines. The efficiency of modern reproduction makes it pos- for an artist to design in almost any medium, with the nable hope that his intentions shall not be travestied on rinted page.

Some Notable Work.—Some of the best examples of the use of the half-tone and line-block processes in England are still to be found in *Punch*, and range from the graceful, elegant manner of Lewis Baumer and (until recently) of Claude A. Shepperson, to a sympathetic treatment of proletarian types in George Belcher's reproduced pencil drawings. The "sequence picture," influenced by the cinema, but drawing its first inspiration perhaps from Caran d'Ache, receives competent treatment at the hands of H. M. Bateman and "Fougasse." W. Heath Robinson in known not only as a comic artist of fantastic invention, but as a delicate illustrator of fairy tales. More purely decorative is the work of Edmund Dulac, who relies, as does also Arthur Rackham, on the three-colour process. The last three artists named have done much to raise the standard of the illustration of children's coloured books. The nursery picture-books of about 1900, in spite of the previous example of Kate Greenaway and Randolph Caldecott, were often crude in colour and ugly in design.

The influence of Beardsley is seen in the work of John Austen, Harry Clarke and "Alastair," while artists like H. M. Brock continued the Hugh Thomson tradition. F. Cayley Robinson and Russell Flint are perhaps best known for their painting, outside the sphere of illustration, but they have both done good work within it. Ethel Gabain (Mrs. John Copley) may be included in the English school, although her most important lithograph illustrations have been issued by French publishers. Two able architectural draughtsmen are E. H. New and F. L. Griggs, while Frank Brangwyn brings to the illustrations of books, such as Southey's *Life of Nelson* and Kinglake's *Eothen*, the same power of emphatic statement and grandiose conception as distinguishes his larger work. The early death of Lovat Fraser cut short a career of great promise which, in spite of its brevity, has exercised a far-reaching influence on various British arts. His method of working in flat tones and simple outline was peculiarly suited to modern colour-reproduction, and his example has been widely followed. Of the more "advanced" artists, many of whom have exploited the possibilities of the original woodcut, may be mentioned V. Gribble, R. Gibbings, Paul Nash, Albert Rutherston, Ethelbert White, A. Buckels and S. Gooden. The last-named has done much to revive the use of line-engraving on copper.

French Workers.—Enthusiasm for the original wood-engraving is greater perhaps in France than in any other country, and so much excellent work has been done by this method alone that the chief difficulty lies in the selection of representative names. A more or less homogeneous group is formed by Maxime Dethomas, with his dignified line, Hermann-Paul, with his broad handling and strong dramatic feeling; and Carlègle. The well-known *éditions Crès* are decorated admirably by Gus Bofa, by Siméon, by Sylvain Sauvage, by Contel and by Daragnès. The last-mentioned artist has used etching as well as wood-engraving, and indeed—now that the chief aim of the woodcut, to harmonise with the printed page, has been generally accepted—there is no reason why artists should not avail themselves of lithography, as does L. A. Moreau, or of line-engraving, like Laboureur, or of etching, like C. Laborde. Mention should be made of the colour woodcuts of Falké, the work of Brissaud, of Deslignères, of Galanis, whose curious use of white hachures is well known to English amateurs; of Raoul Dufy, better known in England as a painter; of Paul Vera, of Laboureur, with his curiously effective deformations; of Jean Marchand, and of Raphaël Drouart, all of whose work goes to make this present epoch of book production in France a very notable one.

Germany.—Germany perhaps more than any other country has felt the influence of the most extreme aesthetic theories. The disorder following the War and the sense of humiliation in defeat tended to anarchy and disillusionment in the arts also. An amazing number of fine books has been produced, but the illustrations to some of these are conceived in a slap-dash, sketchy fashion, impossible to harmonise with the necessary orderliness of a printed page. Even artists of the standing of Lovis Corinth and Max Slevogt sometimes scribble over, rather than illustrate, the works entrusted to them. The mass of modern German

ritish Standard Specification for Portable Photometers, No. 1925).

ritish Standard Specification for Industrial Reflector Fittings lectric Lighting, No. 232 (1926).

work, however, is impressive. A few names may be singled out:—Max Pechstein, Alfred Kubin, Willy Geiger, Fritz Heubner, Julius Diez, Oskar Oestreicher, Wilhelm Wagner, Richard Seewald and George Grosz, the last-named being an able artist who exemplifies that curious obsession with sex which characterises too much modern German art. The general standard of book production in Germany is higher than it has ever been, and it is from Germany that the smaller countries of Europe, with the possible exception of a francophil Poland, draw most of their inspiration.

United States.—The comprehensive word "illustration" covers two main branches of the art—the self-contained picture and the picture which forms the amplification of a literary theme. In the former, the illustrator is called upon to supply a picture of some situation of life or some theme or fantasy, complete and self-explanatory. In the latter, the illustrator has to embellish sympathetically the meaning of his accompanying text.

The subdivisions in both these classes are numerous. The self-contained illustration can be anything from a comic strip drawing to a poetic fantasy, but it essentially has to rest on its own individual merits. The illustration which has a literary partner can be anything from an advertising design to the pictorial embellishment of the finest periodical, book or treatise. These are the extremes covered by the word Illustration.

Perhaps the most prevalent and important branch of the art today is the illustration of magazines, books and newspapers. In recent years this art has reached a very high degree of proficiency, both in artistic technique and in the process of reproduction. Indeed it is probable that the vast improvements in reproductive methods and the refinement of paper have acted as incentives to illustrative artists. Illustrations for books, magazines and papers should be wedded to the text, and at the same time should extend the meaning of the text by their realistic, artistic or imaginative quality.

Most illustrations of to-day have realism as a predominating feature; it therefore might be argued that the great advances in artistic photography might supersede the hand-made illustration, but it is not so. The art of the illustrator cannot be dispensed with, for in its best form all the necessary realism is there, plus the almost indefinable pleasure which technique produces on the observer, whether he be an artist or not.

The best fiction illustration of the period is perhaps to be found in America. There are several very powerful illustrators in Europe, but on the whole the American illustrator excels. Amongst the many exponents of the art, selection is difficult, but it is not easy to imagine better or more applicable illustration than the work of Dean Cornwell in half tone and Dana Gibson in line—both men being leaders of schools of illustrative thought. The mere mention of these two names makes it hard to refrain from enumerating a host of other most capable illustrators, but space will not permit. The English counterparts to the above two artists are difficult to select, but the work of Frank Craig in half tone and of Frank Reynolds in line have provided some exquisite illustration. The work of all four has allowed artistic technique to help the story and yet not engulf it. They have all been great "stylists" and have many followers.

This analysis of illustration as an art holds good throughout the world, and in theory has been approximately the same since man became capable of illustration in even the primitive forms. There have naturally been modifications and peculiarities in ability and style due to elementary conditions; and there have been differences of technique, due in the main to racial causes. (B. B.)

IMMIGRATION: *see* MIGRATION.

IMMINGHAM, England, a seaport situated on the Lincolnshire shore of the Humber estuary, 9 m. S.S.E. of Hull and 5 m. N.N.W. of Grimsby, England. Constructed (1906–12) by the Great Central Railway Co. (now part of the London and N Eastern), the dock comprises a square basin and two long a (including a graving dock) running parallel to each other on western side, of a total area of 45 ac., with 5,400 ft. of quay the depth (30–35 ft.) is sufficient for practically any vessel af The dock is specially designed and equipped for dealing with coal, timber, grain and wool trades, and was officially ope by the King on July 22 1912. The area of the dock prope 2½ m. in length and 1 m. in greatest depth, is just over 1,000 with a river frontage of 1½ miles. The site was chosen beca the deep-water channel of the Humber, which lower down midway between the shores, here makes an inward sweep leads right to the dock gates, thus obviating much initial dr ing, providing ingress and egress at any state of the tide, rendering the towage of vessels unnecessary.

The original village of Immingham lies a little inland, b new town is growing up near the docks. The Grimsby ele tramways have been extended to Immingham and, in addi a light railway runs between the two places.

IMMUNITY (*see* BACTERIOLOGY, 3.175).—The term "im nity" is used in science in the technical sense. An ani is described as *naturally immune* against the microbe of dis if the microbe in question cannot establish itself in the orga and as *artificially immune* if it was naturally susceptible and been rendered insusceptible. Similarly, an animal is descri as *naturally immune* against a poison if its organism is natur proof, and as *artificially immune* if its organism has been dered proof against the poison.

Natural Immunity.—A few words may be said first respect to natural immunity against infection. We may tribute the fact that the body normally remains free from crobic infection to a conjunction of causes:—*First*, to the that its external and internal coatings furnish mecha protections against infection (this point need not be furt considered here); *secondly*, to the fact that the body is equi with special machinery for the destruction of microbes nature of this machinery will be discussed below in connect with acquired immunity); and, *thirdly*, to the fact that cert of the conditions which normally prevail in the animal orga are inimical to the growth of microbes as a whole or at any to the growth of certain classes of microbes. Of the conditi here in question two which are of quite dominant importance discovered in the course of researches on wounds carried in the World War.

Antitrypsin.—The first and more generally importan the antitryptic power of the blood fluids. Such antitry power will in every case hamper, and in the ordinary case pletely inhibit, bacterial growth. It will achieve this by tralising, in part or completely, the digestive ferments of microbes which would otherwise convert the unassimil native albumens of the blood-fluids and serous discharges assimilable nutrient materials. Antitrypsin in the bl fluids will therefore mean for the microbes therein implant either, a restriction of their food supply, or complete starvati The facts, as far as known, all comport with this inference.

To begin with, only a few species of microbes (the stap lococcus, streptococcus, pneumococcus and perhaps the crobes of all genuinely septicaemic diseases) can proliferate antitryptic blood fluids. Further, these microbes (we conveniently call them *serophytic* microbes) produce w grown in plasma (we are here generalising from observati made with staphylococcus and streptococcus) trypsin wh quenches the antitryptic power of the surrounding blood flu and then digests vacuoles in the surrounding clot. Again, serophytic microbes grow very much more vigorously (t streptococcus for example very many thousand times m vigorously) in the blood fluids when these microbes have, by artificial addition of trypsin, been relieved from the task themselves producing enough trypsin to quench the an tryptic power of the surrounding medium. And finally, all the kinds of microbes which are unable to grow in antitryptic blo fluids begin to pullulate there the moment trypsin is added

et it be noted here that a spontaneous addition of trypsin
s regularly in wounds as soon as the emigrated leucocytes
roken down under the influence of bacterial growth and
ourable external influences.

ect of Alkaline Reaction.—Again,—and here the second of
estraints on microbic growth spoken of above comes into
ion—in the course of research work on wound infections
icted in the course of the War, it was established, in con-
on with the microbe of gas gangrene, that the prolifera-
of this bacillus in the blood fluids and serous effusions is
ited not only by the antitryptic power but also by the
al alkaline reaction of these media. Proof of this is fur-
d by the fact that as soon as the alkaline reaction in ques-
is blunted off by the ante- or post-mortem formation of
acid in muscles deprived of their blood supply, or more
tly by an infusion of any acid into the blood, the bacillus of
ene multiplies without restraint.

tural Susceptibility.—The problem as to why a particular
al is naturally susceptible to particular poisons is likewise a
ical problem, but a chemical problem of a different order.
ulated in the technical terms which were introduced by
ch the problem is that as to why the tissues of the insus-
ble animal contain no *receptors* for the poison, that is to
no organic substratum upon which that poison can anchor
. This is a question of the aboriginal chemical consti-
n of the body—a question as to why a particular species of
al was constructed of one kind of elements rather than of
her.

quired Immunity.—The problem presented by acquired
unity to infections or poisons differs in important respects
that presented by natural immunity. With respect to such
orcement of the natural resistance it will be well to note at
outset (*a*) that it can be achieved apart from any violent
iological commotion; (*b*) that acquired immunity does not
y itself in any altered habit of body; and (*c*) that the con-
n may in many cases be present to-day and gone to-morrow.
these facts indicate that the acquired immunity cannot
lve anything in the nature of a revolutionary physiological
aval such, for example, as a fundamental alteration in the
l elements, or a cutting out of receptor elements from cells.
ticipating here, we may say that later it will be shown with
rd to acquired immunity to infections that this depends
the development of (*a*) increased antibacterial substances
e blood fluid; (*b*) increased efficiency in the leucocytes and
ncreased capacity for producing antibacterial substances in
onse to infection. Similarly it will be shown with regard to
ired immunity to poisons that this depends upon the ap-
ance of neutralising elements (so-called antitoxins) in the
d coupled with the acquirement of increased capacity for
orating these elements in response to an incorporation of
corresponding poisons.

arly Doctrines.—Confining ourselves to the problem as to
the bacterial infections are combated in the organism, we
begin by considering the two chief opposing doctrines which
promulgated, when, under the prompting of Pasteur's prac-
achievements in the field of prophylaxis, problems of im-
ity began to be first seriously considered. These theories
ded natural as well as acquired immunity.

umoral Theory.—In the theory which goes by the name of
humoral theory, natural immunity is attributed to the
ericidal substances contained in the normal blood fluids,
acquired resistance to the acquisition or increase of such
ericidal power. The general thesis, at any rate, of this
ry stands secure. Where microbes are killed otherwise
by physical agencies or by inanition, their destruction must
itably result from some form of chemical action. So, too,
acquisition of greater power of destruction must of necessity
nputed to the achievement of more potent chemical powers.
he other hand, it cannot of course be *a priori* certain that
antibacterial elements concerned in the destruction of
obes will be found in the blood fluids and only in these.
t the blood fluids do, in point of fact, possess bactericidal
power was demonstrated by Fodor and Nuttall, and it was at first thought, though a careful study of Nuttall's results should have prevented this, that such bactericidal action was exercised upon microbes without distinction of kind. Later research has, however, shown that the blood fluids are directly poisonous only for certain species of microbes such, for example, as the typhoid bacillus and the cholera vibrio. Certain other species of microbes, and in particular the microbes of specifically septicaemic diseases are, as we have seen, serophytic—the number that grow out in serum being as great as the number which grow out in the best artificial nutrient medium. Thus, the so-called *humoral theory*, though it would account for the organism possessing considerable resistance to typhoid and cholera, leaves unexplained the fact of the normal organism offering very considerable resistance to serophytic microbes.

What applies to natural, applies also to acquired immunity. There is nothing to show that increased resistance to serophytic microbes and septic infections generally is accompanied by the development of any bactericidal power in the blood fluids.

Phagocytic Theory.—An entirely different conception of immunity is that familiarly known as Mechnikov's *theory of phagocytosis.* In the humoral theory the problem of immunity is envisaged from the point of view of the bacteriological specialist and to some extent also from the standpoint of the chemist. Mechnikov for his part approached the problem from that of the morphologist who takes the whole field of animal life as his province. His theory of immunity therefore starts with the generalisation that the protozoa feed upon the lower forms of life such as microbes. It further regards the fact that the higher animals have been evolved out of colonial aggregations of protozoa. In every such colonial aggregation certain of the associated cells instead of becoming specialised persist in the condition of wandering cells.

With regard to these free-living members of the protozoal colony Mechnikov divined that they function as defensive cells. And he showed in connection with sponges and other invertebrates that these wandering cells collect round invading microbes and other foreign intrusions and that they thereafter proceed to ingest and digest them or, to aid otherwise in their elimination. Lastly Mechnikov pointed out that the leucocytes of the vertebrate were homologous to those wandering cells and performed exactly the same defensive offices. In particular when leucocytes emigrate from the capillaries into a focus of bacterial infection, in the normal case, they follow this up by ingesting the intruding micro-organisms, and killing them intracellularly. *Natural* or *native immunity* was thus, in the conception of Mechnikov, due to efficient leucocytic functioning; and *acquired immunity* to the leucocytes having by a *process of training* (as he called it) acquired a power of more effectively confronting, ingesting and destroying microbes.

Eclectic Theory.—The central tenet of the Mechnikov theory—the tenet that the leucocytes play a very important rôle in the defence of the body against infection—has now found universal acceptance, but at the same time the doctrine that resistance to infection depends in every case on the action of the leucocytes has proved untenable. In connection with the defence of the organism we must distinguish between (1) defence against infection by serophytic microbes, that is against microbes which like the streptococcus and staphylococcus proliferate in the normal serum, (2) defense against infection by microbes which are incapable of multiplying in the antitryptic normal serum but are not directly killed by it, and (3) defence against microbes which are directly killed by the serum.

(*a*) In connection with the first kind of microbe the fact that although they grow freely in the serum and plasma, these are killed in large numbers in the blood and in the serum, when living leucocytes are added, shows that the cellular elements of the blood here do the work of destruction.

(*b*) In connection with the successful killing of these microbes, the leucocytes must, however, in all cases have free mechanical access to the microbes. There would for example be default in this respect if, as would happen in dealing with infected defibrinated or infected centrifuged blood *in vitro*, the leucocytes settled to the bottom and the microbes were buoyed up out of their reach in the serum. The same would of course happen *in vivo* in all serous effusions.

(*c*) In connection with those microbes which are not directly poisoned but fail to proliferate in the serum, the most important restraining influence is the native antitryptic power of the blood, but once the antitryptic inhibitory action of the blood fluids and serous effusions has been neutralised the leucocytes, even when everything else favours them, will be impotent to inhibit microbic growth. On the contrary as soon as the leucocytes degenerate they will furnish a further quantum of trypsin and in this way directly conduce to the pullulation of all manner of microbes.

Lastly, the leucocytes do not seem to contribute to the defence of the organism against those microbes which, like the typhoid bacillus and the cholera vibrio, are directly poisoned by the serum. When we implant such microbes into defibrinated blood and then incubate and make microscopic preparations those microbes which are quickly ingested are found intact within the phagocytes while those which are left exposed to the action of the serum are distorted and dissolved. And again, when living emigrated leucocytes are brought to bear upon typhoid bacilli it would seem that few of the microbes are killed. Precisely similar results are obtained with extracts made from leucocytes. It was shown by Schattenfroh that such extracts exert bactericidal action upon the staphylococcus and streptococcus while they exert no such action upon the typhoid bacillus and the cholera vibrio. And again it was shown by Colebrook that the products of inflammation derived from foci of inflammation set up by incorporating into rabbits lint soaked in typhoid vaccine are powerfully bactericidal for the staphylococcus and streptococcus while for the microbes of typhoid and cholera they are not more bactericidal than ordinary serum.

This review of the facts shows that only in the case of serophytic microbes does the defence of the body depend upon the leucocytes and that when it is a question of defence against the other two classes of microbes (those whose growth is entirely inhibited and those which are directly poisoned by the serum) the leucocytes are either impotent or directly harmful.

Properties of the Leucocytes Concerned in Immunisation.—Mechnikov originally taught that the leucocytes were attracted to microbes and induced to phagocytose them by the toxin secreted by the microbes; and that there was here only an interaction between leucocytes and microbes and that the blood fluids could be left entirely out of the story. That that doctrine cannot be sustained can be demonstrated by a very simple experiment.

We begin by receiving a sample of blood taken direct from the vessels into normal salt solution. We then centrifuge and recentrifuge in further volumes of this normal salt solution so as to wash the cellular elements free from all traces of the blood fluids. We then make two so-called *phagocytic mixtures* combining in the one case (*a*) one volume of a bacterial suspension with (*b*) one volume of washed leucocytes and (*c*) one volume of 0·85% *salt solution*; and in the other case (*a*) one volume of washed leucocytes, (*b*) one volume of the same bacterial suspension and (*c*) one volume of *normal serum*. These mixtures are then placed in the incubator and after a suitable lapse of time a sample of each is examined under the microscope. In the first phagocytic mixture—that in which no serum was employed—the leucocytes have failed to ingest any microbes. In the specimen in which serum has been employed, the microbes have been plentifully ingested. This result depends not upon any stimulating effect exerted upon the leucocytes, but upon the fact that the serum has effected a chemical change—a so-called *opsonic change*—in the microbes. That this *opsonic change* does not in any sense affect the vitality of the microbe is shown in the case of serophytic microbes by the fact that the serum that exerts an opsonic effect furnished culture medium in which the affected microbes will all grow out into colonies. The blood fluids intervene further in the destruction of microbes in the interior of the phagocyte by combining with them in such a way as to favour their intracellular digestion. This action, which first described by Douglas, is known as the protryptic actio the blood fluids.

The living leucocyte can also kill microbes apart from ph cytosis. The following experiment is instructive. A shal receptacle is filled with a solid nutrient medium whose sur has been uniformly implanted with staphylococcus or stre coccus. The centre portions of the three cover glasses are thi carpeted with living leucocytes obtained direct from the bl We now, after different treatment, impose these cover gla side by side upon the implanted nutrient surface. In the cas the *first* cover glass the adhering leucocytes are brought application in conjunction with the adhering serum; in the of the *second* they have been washed free from every trac serum; and in the case of the *third* cover glass the adher leucocytes, instead of being employed living, have been ki by drying.

The whole preparation is now incubated at blood heat 12 hours or more. The microbes will then be found to have gro out forming an uninterrupted sheet of colonies over the wh surface of the nutrient medium except under those areas cover glasses 1 and 2 which are carpeted with living leucocy Here the implanted microbes have not proliferated, and mic scopic examination of the cover glasses shows that where leucocytes came into action in conjunction with serum microbes are all lying intracellularly; while where the leucocy were washed free from serum— the microbes are all lying ext cellularly. The experiment thus shows that microbes can killed by leucocytes both intra- and extra-cellularly, *i.e.*, both phagocytosis and also apart from phagocytosis. This holds t both under the conditions obtaining in this particular experime and also in numerous other conditions. That destruction microbes by leucocytes without the intervention of phagocyt occurs also very frequently *in vivo* is practically certain.

Results of Experiments.—Research has thus shown that destruction of microbes in the body does not proceed only al the lines laid down in the humoral and phagocytic theor Instead of there being, as was assumed in those theories, o one physiological device by which microbes without distinct are killed in the organism, nature would appear to prov different distinctive devices for different microbes. Some pa ogenetic microbes are combated by the bactericidal action the serum unassisted by the leucocytes, others again are p vented from proliferating by special agencies, such for example the antitryptic power of the blood; and again a third descripti of microbe, the serophytic microbes, are destroyed intra lularly and extracellularly by the leucocytes aided, or as the c may be, unaided, by the blood fluids.

The above deals only with the normal protective machine of the body as distinguished from that which comes into p in artificial immunity. In connection with the latter Me nikov, as will be remembered, taught that acquired resi ance was due not to any changes in the blood fluids, but to t leucocytes having been subjected to a process of training whi gave to them a greater capacity for confronting and ingesti microbes. This doctrine had to go by the board when it was sho in numberless cases that increased phagocytosis goes hand hand with increasing opsonic power in the blood fluids.

From this it was incautiously assumed—though this te was never definitely formulated—that the leucocytes co stitute in artificial immunity an invariable, and the blood flui the only variable, factor. That the phagocytic efficiency of t leucocytes was also a variable factor was first shown by Shatto and Dudgeon, who observed that the phagocytic efficien of the patient's leucocytes is in many cases of pyrexial infecti greater than that of the normal man. The phagocytic efficien of a patient's leucocytes may also, as was further shown Shattock and Dudgeon, be less than normal.

These observations have a direct bearing upon Mechniko doctrine with respect to acquired immunity, since, in all infe tions which are associated with constitutional disturbance antigens from the foci of infection are being brought in tion—in other words the organism is experiencing and is ng to *auto-inoculations*. It follows that, conformably with loctrine of Metchnikov, the leucocytes should in every of pyrexial infection be conducted by successive degrees to ndition of continually increased phagocytic efficiency. ad of that these cellular elements are, sometimes in localised ions, and practically always in streptococcus septicaemia, ed to a condition of diminished efficiency.

tificial Immunisation.—We have to consider next how to ase the effectiveness of the anti-bacterial machinery, *i.e.*, how oduce artificial immunisation against infection. The origi- oint of departure was the observation that those patients had contracted and recovered from an infectious disease thereby rendered proof against reinfection. That obser- n led, in connection with smallpox, to the adoption of a dure for the warding off of the disease. The procedure ted in various parts of the world and introduced to Europe Turkey, consisted in the implantation into the susceptible idual of material obtained from a patient suffering from pox. This procedure, which was denoted inoculation be- it resembled the grafting of an *eye* or *bud* into a new stock, reality the parent from which all other procedures of cial immunisation are derived. What required still to be was to purge inoculation of its dangers and to regulate the nising stimulus. This was successfully done in Jennerian nation. But the achievement of Jenner was in point of purely empirical.

steur's Work.—After Jenner came Pasteur and with Pasteur tific methods are for the first time brought into appli- n in connection with prophylactic inoculation. His initial vement was to recognise that the essential in Jennerian nation was that for a virulent infective organism obtained actual cases of smallpox there has been substituted an tive organism which by the operations of nature—to wit ransfer to the cow—had been attenuated in such a manner render it non-lethal for man. By the exploitation of that ral principle, by the employment of pure culture and by a ique of artificial attenuation adapted with infinite resource ch separate case, the whole series of Pasteurian successes in field of artificial immunisation were one after another ved. Artificial immunisation was not, however, purged all its risks by the procedures of Pasteur.

had not yet been transformed into a scientifically regulated dure. The Pasteurian vaccines were in point of fact standard- only thus far that recourse to attenuation placed in each a certain limit upon the proliferation of the vaccinating rial in the organism of a normally resistant man or animal.

ndardisation.—A great step in advance was taken when it established in connection with anti-typhoid inoculation the antigen required for the setting in motion of the machin- of immunisation can be furnished by the incorporation of lised microbic cultures. And further, important steps to achievement of a standardisation of bacterial vaccines made when a technique for the enumeration of the microbes cterial suspensions was devised, and when it was recognised weighed quanta of desiccated and powdered bacterial sub- ce could be employed in cases where, owing to the felting ther of the microbes, enumeration of the microbial suspension impracticable. The counting of the microbes or the weigh- of the bacterial substance is, however, only a means to an —the standardisation of a vaccine, *i.e.*, the determination of doses which will give the best "curve of immunisation."

he Curve of Immunisation.—The expression *curve of immunisa-* calls attention to certain fundamentally important points in ection with the reaction of the body to the incorporation of ines. In the pre-Pasteurian and Pasteurian periods, when s about the nature of immunising response were still vague, as assumed with regard to vaccines that they produced effects only after a certain incubation period (ordinarily after 10 days). And it was further taken for granted that curve of immunisation would from the beginning move ys in the upward direction. When, however, immunisation curves came to be constructed (and this was done first in connection with anti-typhoid inoculation) unanticipated features revealed themselves and in connection with these also time-relations which did not conform with expectation.

Negative and Positive Phases and Practical Importance of These.—In what may be called the normal case—*i.e.*, in the case where the dose of vaccine inoculated is sufficient to produce an appreciable constitutional disturbance, a bi-phasic curve of immunisation is obtained. For 24 or more hours after the inoculation the antibacterial power of the blood is reduced. This—the so-called *negative phase*—is followed by a phase of increased antibacterial power—the so-called *positive phase*—which may last for one or two or a number of days as the case may be. After this the antibacterial power falls away gradually to a level only slightly higher than the original normal. But despite this there would seem to persist in the organism (and this would seem to be the chief profit from inoculation) a power of making more rapid and more ample immunising response to any subsequent incorporation of antigen whether in the form of a subsequent inoculation of a similar vaccine, or actual infection.

When, instead of a quantum of vaccine which produces a constitutional disturbance, a smaller dose is inoculated, the negative phase is elided and a positive phase is well developed already 24 hours after the incorporation of the vaccine. And, finally, when excessive doses of vaccine, such as produce very severe constitutional disturbances, are incorporated, the negative phase may be correspondingly intense and may persist for many weeks. These facts have an important bearing upon prophylactic operations; they must also, as reflection will show, have an importance in connection with the immunisation procedure to which horses are subjected with a view to their producing antibacterial and antitoxic sera. Again substantially the same relations as between the quantum of vaccine inoculated and the type of response elicited, obtain in the case where vaccines are inoculated into patients who are the subjects of infection. But in that case the conditions are so far different that we have to consider in each case two quanta of antigen: that administered in the vaccine, and that already contained in the patient's organism. Where a patient is the subject of only a minimal infection, we may employ doses of vaccine nearly as great as those employed for the prophylaxis of healthy men. Where a patient is heavily infected, we are restricted to the employment of minimal doses, and finally, when the patient is already labouring under an excessive infection, the injection of vaccines can only do harm.

The principle that the kind of response, and the amplitude of the reaction, and the time-relations of the phases are in each case a function of the quantum of antigen brought into application is found to apply also to the case where the vaccine is added to the extravascular blood. We obtain *in vitro* every variety of effect according to the dose of vaccine brought into application and the time for which it operates upon the blood—the effects varying from an instantaneous increase of bactericidal power to a loss of most of that destructive power. And further different effects are obtained according as we select now one and now another method of testing. We obtain for example one result when we measure the bactericidal power of the whole blood; another when we measure the opsonic power of the serum; a third when we measure the phagocytic efficiency of the leucocytes. It must remain for the future to unravel these complications. For the moment the essential point to note is that the machinery of immunisation which was supposed to be constructed upon a very simple—and one may add foolproof—plan is in reality built up of very delicate and complicated elements.

The lessons which can be drawn from immunisation curves may now be summarised. The first of these is that excessive doses of vaccine may delay and possibly interfere with the prophylactic response, and further that such excessive doses of vaccine administered to patients suffering from an infection may definitely aggravate their condition. Other important lessons are that when appropriate doses of vaccine (*i.e.*, doses which are not followed by a negative phase) are administered, prophylactic effects may be obtained almost immediately after inoculation. And further it should be possible to arrest a general infection by inoculating in the incubation period and then employing a reduced dose of vaccine.

In connection with this attention may be directed to the statistical records of Haffkine's anti-plague inoculations in the Byculla Jail in the City of Bombay, and to the cases put on record by Miss Corthorn. The records of the Byculla inoculations make it probable that a prophylactic effect was here exerted already 24 hours after the vaccine had been given. And the cases recorded by Miss Corthorn seem to make good that attacks of the plague were not unfrequently aborted by the inoculation of the vaccine (*see* PLAGUE).

Further evidence showing that immunisation develops very rapidly after the inoculation of an antigen is furnished in the work of von Pirquet. If a first implantation of vaccinia is followed by similar implantations on successive days, the response to these latter differs from the response made to the first. This altered clinical response—which would appear to indicate a more rapid destruction of the later implanted infective material—was described under the name of *allergy*. It was further shown by Von Pirquet in connection with the inoculation of foreign serum that the supervening clinical reaction—which appears to indicate the throwing out of that foreign serum from the blood—is accelerated when the injection of serum is made into an organism which has been before subjected to that procedure. The interval between the injection of the foreign serum and the clinical manifestations associated with its elimination from the blood (normally 10–14 days) may be reduced to a very few minutes.

Further Questions in Connection with Artificial Immunisation.—A series of further questions in relation to artificial immunity have to be considered (1) Are there agencies other than vaccines proper—in other words, other than living or dead microbes or substances derived from the bodies of microbes—which will affect the bactericidal power of the blood and leucocytes? (2) Again are the antibacterial substances in the serum specific in the sense of operating only upon one particular variety of microbe or are they non-specific? (3) Further, will leucocytes which have acquired increased phagocytic efficiency, ingest more actively only one particular species of microbe, or all microbes without distinction? (4) Finally, what are the cells in the body which elaborate the anti-bacterial substances? All these questions are intimately linked up.

Non-bacterial Vaccine.—In connection with the question as to whether there are agencies other than vaccines proper which can increase or, as the case may be, diminish the bactericidal power of the blood, it has been shown that the infliction of burns increases the bactericidal power of the serum for the anthrax bacillus. This increased bactericidal power is no doubt referable to an absorption into the blood of disintegration products derived from the burnt tissues. Again, it has recently been ascertained that increased bactericidal power can be developed in the blood *in vitro* by adding to it foreign sera and also non-foreign sera which have been artificially altered by heating to 60° C. Lastly, it has been shown in connection with the irradiation of the skin with ultra-violet light, the light of the electric arc and sunlight, that by these agencies also the bactericidal power of the blood is increased, such increased bactericidal power depending upon an increased phagocytic power of the leucocytes and also an increased antibacterial power in the serum (*see* HELIOTHERAPY and PUBLIC HEALTH). It is not yet known how irradiation produces these results, but the consideration that radiations such as are here in question are much more likely to act by breaking down than by building up albuminous substances, taken together with the fact that increased bactericidal power is achieved only with a certain quantum of irradiation and that the blood suffers deterioration when larger doses are employed, would seem to point to the conclusion that we are here, in each case, dealing with effects produced by the absorption into the blood of an antigen in the form of disintegration products generated by the irradiation.

Specificity.—The non-bacterial antigens which have
under discussion above occupy at present a position apa
the respect that it would generally be held with regard to
that they might quite likely evoke a non-specific immun
response; whereas it would be generally held that bacterial
cines would produce only specific immunising response.
against this there is conclusive evidence to show that bac
vaccines also evoke non-specific immunising response in the
of increased bactericidal power in the blood, increased ph
cytic efficiency in the leucocytes and sometimes also incre
antibacterial power in the serum. Thus, for example, by
incorporation of staphylococcus the blood can be rendered
bactericidal for streptococcus. This can be achieved als
the addition of staphylococcus vaccine to the blood *in*
Similarly an addition of tuberculin to the extravascular b
will increase the bactericidal power of the blood to staph
coccus, increasing at the same time the phagocytic efficienc
the leucocytes.

These laboratory experiments are in consonance with the
tistical results obtained in connection with anti-pneumo
coccus inoculations at the Premier Mine in the Transv
Here, in 1912, in addition to a striking reduction in the incid
and death-rate of pneumonia, there was achieved a stri
reduction in the incidence and death-rate from "other diseas

Derivation of Product of Immunisation.—The discussion
the deeper problems as to where anti-bacterial substances
elaborated in the body, and as to how their production is t
explained, may be deferred for a moment. For the facts re
ing to immunisation against bacterial toxins must first
taken into consideration, by bringing out the following poi
(1) The machinery of immunisation is in reality a machiner
neutralising or otherwise disposing of poisonous substanc
poisonous substances being by definition those which enter
crippling or lethal chemical combination with the blood fluids
tissues. (2) The machinery of immunisation achieves its
by furnishing substances which enter, as the case may be,
neutralising or precipitating or destructive union with
poisonous substances above spoken of. (3) The machiner
immunisation is brought into operation only by a partic
class of poisons—to wit, by those which enter into crippling
not immediately lethal chemical combination with the cell
protoplasm—those which, to use the expressions of Ehrl
intrude themselves into the "side-chains" and not into
"vital ring" of that protoplasm. Of such poisons four ki
specially invite attention. These are: (*a*) the poiso
constituents of the bacterial protoplasm, (*b*) the albumi
substances contained in foreign sera and certain other foreig
buminous substances, (*c*) bacterial toxins such as those which
be filtered off from cultures of diphtheria and tetanus an
vegetable and animal toxalbumens such as abrin, ricin and
various snake venoms. With respect to the first the b
responds to their inoculation by a production of *bacterio-tr*
substances, *i.e.*, substances which enter into detrimental or le
chemical combination with bacteria. The inoculation of ser
followed by the elaboration and delivery into the blood of
tropic substances which neutralise and precipitate these s
The inoculation of bacterial toxins in like manner—and t
sovereign discovery was made by Behring—leads to the p
duction and delivery into the blood of toxitropic substan
These, known as bacterial *antitoxins*, neutralise and precipit
the corresponding toxins. And, finally, the inoculation of to
bumens is followed by an elaboration and delivery into the bl
of the appropriate neutralising substances.

Practical Results.—The discovery of bacterial antitoxins
led to important practical applications in connection with
treatment and prophylaxis of, in particular, diphtheria (
INFECTIOUS FEVERS) and tetanus (*q.v.*) By virtue of the
that toxins and antitoxins lend themselves to accurate qua
tative study, it has contributed much to our knowledge of
machinery of immunisation. It was through the study of
curves of immunising response made to the inoculation
tetanus toxin that the negative phase first became kno

it was by the study of antitoxin production that it was for
st time unequivocally established that the organism which
ade previous response to even a minimal quantum of a
s thereafter capable of responding to any further quantum
it poison with a prompter and ampler elaboration of
xins.

ther, by the study of the antitoxin content of the blood in
ation to diphtheria toxin, it has been shown that the pres-
f even a small quantum of antitoxin in the blood protects
st infection, and further that the insusceptibility of the
ity of adults to diphtheritic infection is correlated with the
sion of a minute quantum of antitoxin derived, as it would
from repeated minimal diphtheritic infections contracted
ir earlier life. The same would appear to hold also of the
t fever streptococcus. We have here, as reflection will show,
which illuminate the epidemiology of diphtheria and scar-
and show that it is possible and may under circumstances
visable to substitute for a prophylactic inoculation of a
rial vaccine, an injection of antitoxin, or alternatively an
ion of such quantum of toxin as will evoke an antitoxic
ise.

o further points about antitoxins have important bearings
the problem as to where and how products of immunisa-
re produced in the organism. (1) Antitoxins are quite rigidly
ic—each antitoxin neutralising only the particular kind
in in response to which it was engendered. (2) After a first
lation of toxins antitoxins are only very slowly produced.
arily an interval of 10 to 20 days elapses before they make
appearance in the blood.

ese properties are not, let it be noted, differential properties
titoxins; they characterise also certain kinds of bacterio-
substances. Specificity and comparatively tardy appear-
in the blood characterise for example agglutinins, and the
led "thermostable immune bodies."

ce there are two kinds of products of immunisation:
ind that are eminently non-specific and which are produced
diately (and can, as we have seen, be produced in the blood
ro); and another kind which are rigidly specific and are
rated only after a considerable lapse of time and are so
appears produced only *in vivo*; we may now seek for an
er to the problem as to how and where these various prod-
of immunisation are engendered. Since it may be taken as
n that these two kinds cannot well originate in the same
nd be engendered by the same kind of metabolic operation,
ay divide up the problem and consider first by what cells
y what kind of metabolic operation the non-specific anti-
rial substances are produced and then take up the question
where and how antitoxins and such antibacterial substances
specific are generated.

oduction of Non-specific Antibacterial Substances.—The former
ion presents no difficulty. The facts set forth above make
ar that non-specific antibacterial substances are elaborated
e leucocytes. And further the facts suggest that the leuco-
produce these substances as ordinary secretion incited
e chemical products derived from bacterial and cellular
egration products applied in suitable concentration.

rther the facts comport with the idea that leucocytes which
elaborated antibacterial secretions but have not as yet ex-
l these into the environing blood fluids will, by virtue of
increased content in antibacterial substances, possess in-
ed antibacterial efficiency, while the blood fluids will not
gained anything in antibacterial power.

nversely leucocytes that have excreted their antibacterial
ances will exhibit diminished antibacterial power and the
fluids which have received these secretions will have
ed an accretion of antibacterial power.

*oduction of Specific Products of Immunisation: Ehrlich's
hain Theory.*—The problem as to how these products of
nisation which indenture chemically with only one counter-
substance are engendered in the body, is of quite another
of difficulty, and it is one of the memorable achievements
rlich to have conceived how the furnishing of such specific products of immunisation could be accounted for. The problem presented itself to Ehrlich's mind in the following vivid manner: "If," it was thus that Ehrlich communed with himself, "If I take a guinea-pig—that is to say, a creature whose country of origin is Southern America—and administer to it abrin—a poison derived exclusively from Africa (and thus one which neither the tame guinea-pig nor its ancestry can ever have encountered) and if I now find that my guinea-pig furnishes me with an antidotal substance which indentures with the abrin as does a key with the wards of the lock for which it is made, is there then for me any way of escape from the conclusion that the organism of my guinea-pig has specially constructed an antidotal substance to fit the particular kind of poison I have administered—performing in this a feat of chemical analysis and synthesis which would balk the ablest chemist?" From the intellectual *impasse* into which this interrogatory seemed to conduct there was, Ehrlich discerned, a possible way of escape. He reflected that there must of necessity exist in the organism of any animal which is affected by a given poison a counterpart substance (or to use his technical term) a *receptor* which enters into chemical combination with that poison. In other words there must exist already preformed in the organism of susceptible animals, substances which have a chemical constitution such as would admit of their functioning as antitoxins.

At the same time these counterpart substances differ fundamentally from the non-specific antibacterial substances which were considered above. First of all they are not, as are the substances last mentioned, available in the form of secretory products produced only with a view to their being ejected from the cell. Instead of that, specific counterpart substances are integral elements of the cellular protoplasm, and elements of which it may be assumed with certainty that they subserve special functions in the internal economy of the cells of which they are constituents. Further the specific counterpart substances we are here considering differ from the non-specific antibacterial substances in the respect that while these latter are elaborated only in one particular variety of cell (to wit, in the leucocyte) the former are widely distributed in the organism, being located in each case in a different assortment of cells. Thus, for example, the counterpart substances to which the diphtheritic toxin would anchor itself would be located in a different assortment of cells than the counterpart substances with which the tetanus toxin would combine. And again the counterpart substances which would combine with abrin would be different. This would hold true also of the counterpart substances which would unite with the poisons derived from each particular variety of bacterial protoplasm.

So far it has been shown only that susceptible animals must by the very nature of things contain in their cell-protoplasm constituent elements which are the exact chemical counterparts of poisons. We are still very far from the solution of the mystery (*a*) of the organism furnishing antitoxins in the circulating blood; (*b*) of its furnishing antitoxins only to special classes of poisons; and (*c*) of its furnishing these in quantities far in excess of the quantum of counterpart substances originally contained in the organism. Ehrlich, in exploring for some way of exit from the labyrinth constituted by these questions oriented himself by the aid of a ground-plan, in which there was set out his general conception of the stereo-chemistry of protoplasm. In the plan in question the protoplasm is a structure made up of side-chains assembled round a central ring—the continued life of the protoplasm depending upon the integrity of the central (or as we may call it *vital*) ring; while the side-chains consist of elements which are integrated into the protoplasm for its nourishing and vital functioning. To this original ground plan there was now added by Ehrlich a new feature. The conception which he now added was that the side-chains of the protoplasm would, as soon as they became redundant, be cast forth from the cell into the circulating blood, forming there what he called *free receptors.*

Interpreted in the light of this so-called *side-chain* theory, the incorporation of poisons which make a chemical attack upon the vital ring of the cell protoplasm would abrogate the life of the cell and would therefore be incompatible with an elaboration of antitoxins. The situation is entirely different when the poison, instead of directing its attack to the vital ring, anchors itself on to one of the side-chains. After a temporary putting out of action of those functions which are discharged by the particular side-chains in question, this would lead to the replacement of the crippled side-chains, and thereafter to a hyper-replacement and to such redundancy of these in the protoplasm as would involve casting forth these side-chain receptors into the circulating blood. This theory, which is quite as applicable to the production of specific antibacterial substances as to the production of antitoxins—would seem to lie open to critical assault in that the hyper-replacement of side-chains does not necessarily conduct to an excretion of these into the circulating blood. In point of fact in the case of muscle, on which Ehrlich here relies, it leads to something very different, to a hypertrophy of this tissue.

Finally, the side-chain theory has met with hostile criticism more especially on the ground that it would compel us to believe that the noble tissues, such as those of the central nervous tissue which are poisoned by the toxins of diphtheria and tetanus, can be converted into secretory organs so prolific as to furnish in the blood tens and hundreds of thousands of units of the corresponding antitoxins. In point of fact the side-chain theory does not in any way require us to believe this. It would do so only if it had been established that poisons such as diphtheria and tetanus toxins attack only the central nervous system. But in point of fact Ehrlich assumed that the poisons which are responded to by a production of antitoxins are all *polytropic*—in other words they turn towards and combine chemically with a number of different tissues. So far therefore as the side-chain theory is concerned, we are thus authorised to assume that, not the cells of the central nervous system, but all or any of the other and less noble tissues which are affected by the toxins, are those which produce the harvest of antitoxins.

See E. Mechnikov, *Immunity in Infective Diseases*, trans. by F. G. Binnie (1907); Sir A. E. Wright, *Technique of the Test and Capillary Glass Tube* (1921). (A. Wr.)

IMPERIAL PREFERENCE.—This consists in the charging, by states belonging to the British Empire, of lower import duties on goods coming from another state of the Empire than on like goods coming from countries outside the Empire, or in exempting Empire goods from duty altogether.

History of the Movement.—Until after the middle of the 19th century, colonial products enjoyed a preference in the customs tariff of Great Britain, and British goods in the tariffs of the colonies. Preferences in both directions disappeared about the same time. But while Great Britain removed tariff restrictions equally from all imports, from whatever source, the Colonies—now obtaining responsible government, and looking upon customs as the only available source of public revenue—proceeded to impose equal duties on all imports, from whatever source. The British Govt. in vain protested in 1859 against the imposition of duties by Canada on British goods. The Govt. of Canada insisted on "the right of the people of Canada to decide for themselves both as to the mode and extent to which taxation shall be imposed." The principle of tariff autonomy was henceforward acquiesced in by the British Govt. and acted upon by the self-governing colonies.

This was the situation for almost 40 years, in the course of which colonial tariffs became distinctly heavier. So great, however, was the reliance in Great Britain on the most favoured nation clause in her commercial treaties with European countries, that by her treaty with Belgium in 1862 and with the German Zollverein in 1865 she actually bound her colonies, without consulting them, to grant as favourable treatment to the products of the treaty country as to those of the mother country, *i.e.*, to grant no preference to Britain.

Changed Sentiment.—A new stage in intra-imperial trade relations was opened in 1897. In that year Canada granted tariff concessions to all countries treating her on equally favourable terms. In effect this was a preference to British goods; and in 1898 the Canadian Tariff Act was converted from or general reciprocity to one avowedly of British preference. Imperial Govt. had already in 1897 given notice to termi the treaties with Belgium and the Zollverein.

In 1902 the policy of Canada became the policy of the Do ions. At the Colonial Conference of that year in London following resolution was passed:—

> That . . . it is desirable that those colonies which have n ready adopted such a policy should, as far as their circumsta permit, give substantial preferential treatment to the pro and manufactures of the United Kingdom. That the prime isters of the colonies respectfully urge on H.M.'s Govt. th pediency of granting in the United Kingdom preferential t ment to the products and manufactures of the colonies, eith exemption from or reduction of duties now or hereafter imp

Effect was given to this resolution by New Zealand South Africa in 1903 and by Australia in 1906.

Tariff Reform.—Meanwhile in England the re-impositio revenue purposes in 1902 of the old registration duty of 1 shill quarter on imported wheat had raised hopes of preferen Canada which were defeated by the abolition of the duty year. The episode completed the conversion of Joseph Ch berlain to the principle of preference; and imperial prefer was a prominent element in the policy of Tariff Reform w he laid before the country in 1903. The movement, how failed at the time to receive sufficient popular support in G Britain. At the next Colonial Conference in 1907, though resolutions of 1902 were reaffirmed by the colonial represe tives, the British Govt. put in a definite reservation that could not assent in so far as the resolutions implied that it necessary or expedient that the fiscal system of the United K dom should be altered.

Progress during the War.—The World War and the gene support which the Dominions gave the mother country considerable effect on public sentiment in Great Britain. E in 1917 the important committee appointed by the Govt consider commercial policy after the War (presided over Lord Balfour of Burleigh) recommended:—

> That H.M'.s Govt. should now declare their adherence to principle that preference should be accorded to the products manufactures of the British overseas dominions in respect of customs duties now or hereafter to be imposed on imports the United Kingdom.

A few weeks later the Imperial War Conference expressed i in favour of "the principle that each part of the Empire, ha due regard to the interests of our Allies, shall give spec favourable treatment and facilities to the produce and manu tures of other parts of the Empire": a resolution now pa unanimously by the representatives no longer of the Domin alone but also of Great Britain. In April 1917 Mr. Lloyd Ge and Mr. Bonar Law, on behalf of the Coalition Govt., annou their acceptance of the principle of preference, making it c that this did not involve the taxation of food. In Sept. 1 the British Govt. withdrew from the Brussels Sugar Conven on the express ground that they had "now approved the prin of giving preference to Empire sugar." And, finally, in Finance Act, introduced by Mr. Austen Chamberlain as Ch cellor of the Exchequer in April 1919, preferential rebates imports from the colonies or exemption from surtax were gran on practically all articles dutiable under the existing tariff.

The range of dutiable articles had been increased under st of war. For many years before 1915 the only duties imposed Britain were either purely for revenue purposes—those on cocoa, coffee, sugar and tobacco; or for revenue with a cert mixture of ethical motive—those on wines and spirits. the Finance Act of 1915 had introduced duties also on cert manufactured goods (the "McKenna duties")—cinema fil clocks and watches, motor-cars and musical instruments. Th were intended as luxury taxes, but had some protective eff On these the measure of 1919 was now able to give preferen

Post-War Changes.—The area of preference was still furt enlarged by the Safeguarding of Industries Act in 1921. I. of this Act provided for the imposition of duties on cert es produced by "key industries." The list included cameras ptical lenses and a large number of scientific instruments pparatus, chemicals and special appliances, deemed essen- r the safety of the Empire; and from these duties Empire were entirely exempted.

e growth of manufactures in Canada had affected the sit- n by enlarging the possibility of advantageous preference eat Britain beyond the primary foodstuffs: motor-cars are ample. A similar extension of possibilities from Australia brought about by the growth of fruit farming, largely as esult of the settlement on the land of ex-soldiers. The h Govt. took the opportunity of the Imperial Conference 23 to announce its readiness to enlarge the existing pref- e on dried fruits, to increase the rebate on Empire tobacco n certain wines, and to take other action of a similar char- Before these promises could be fulfilled, the Baldwin fell from power. The MacDonald Ministry which followed ed to carry out the intentions of its predecessors; abolished IcKenna duties; and, though it did not entirely throw over ence in revenue duties, so reduced the tax on sugar, tea ried fruits as to make the preference of less value.

ferences Granted by Britain.—On the return to office of Mr. vin at the end of 1924, the McKenna duties were restored the accompanying preferences; and the preference on dried , tobacco, wines and sugar was increased. The range of ence was further widened in two directions. The new uarding of Industries (Customs Duties) Act, 1925, imposed s on imported cutlery, gloves and incandescent mantles; the budget of that year introduced duties on silk, natural rtificial. To each of these new duties, Empire preference ttached.

ce the first grant of preference to the mother country by reat Dominions, changes have from time to time taken both in the general rates of duty and in the extent of the ence. In 1923 Canada, having in mind the removal of n restrictions on the importation of cattle into the British et, undertook to give a discount of 10% on existing duties ritish goods coming through Canadian ports. Australia sed its preference to British goods in 1920, and gave assis- to British trade both by anti-dumping legislation and by ures with respect to dyes. And during the last two decades le complex of preferences has grown up between the several nions and Colonies, many of them the result of definite es. And thus Preference within the British Commonwealth tions has already become a considerable factor in the eco- and political world situation. (*See* also TARIFFS.)

LIOGRAPHY.—The least partisan and most complete history of hole movement down to 1921 will be found in a *Report* on ial Tariff Policies (1922), prepared for the U.S. Tariff Com- on. Much information as to the views of the Dominions and as volume of trade affected is given in the *Record of Proceedings* e Imperial Economic Conference of 1923 (Cmd. 2009, 1924). ature and extent of the preferences accorded to Great Britain, to March 1925, together with the conditions governing the ssions, will be found in the *Survey of Overseas Markets* (1925) e Committee on Industry and Trade appointed by the British in 1924. That committee reported that "while it is difficult to n any exact statistical measure of the benefit to British trade of eferential treatment, the surveys of British Dominion markets he statistics of distribution of British trade leave no room for that the advantage has been substantial." (WM. A.)

PRESSIONISM: *see* PAINTING.

CHCAPE, JAMES LYLE MACKAY, 1ST VISCOUNT (1852– , British shipowner, was born at Arbroath, Forfarshire, 11 1852, and educated there and at Elgin. In 1874 he to India to join the firm of Messrs. Mackinnon, Mackenzie mpany, Calcutta, of which he ultimately became senior er; he became a member of the legislative council of the oy in 1891 and a member of the Council of India in 1897. as created K.C.I.E. in 1894. In 1902, consequent upon the r rebellion, Sir James Mackay negotiated a commercial y with China (*see* 6.204); he was then created G.C.M.G. 11 he was raised to the peerage as Baron Inchcape of Strath- Before the World War broke out, Lord Inchcape was already one of the most prominent figures in the British business world. As a representative of the shipping industry he took a leading part in all its affairs both during the World War and after. He served on most of the Government commissions of inquiry both in India and England. He was a member of the Geddes committee on national expenditure (1921), and chairman of the Indian retrenchment committee (1922). In 1924 he was created viscount and G.C.S.I. The positions of chairman of the P. and O. Steam Navigation Company and director of the National Provincial Bank and Suez Canal Company made him a leading figure in business circles.

INCOME TAX (*see* 14.356).—War provides a fertile soil for taxation, and a tax on income has been adopted during and since the World War in some countries which had hitherto rejected this form of direct taxation, long the sheet anchor of British finance.

I. THE UNITED KINGDOM

The British tax has been developed gradually in detail, reflecting at various stages in its history the growth of opinion, equality and justice, until to-day it is a financial instrument of great intricacy, subtlety and power. None the less the broad scheme of the law has remained unchanged in many essential characteristics for nearly a century. Flexibility is provided by the annual re-enactment of the whole income tax code through the medium of the continuation clauses in the yearly Finance Act, which serves also as the medium for amendments, extensions and declarations of the construction of the law.

The salient characteristics of the tax may be grouped under eight heads.

Scope.—The tax extends, broadly speaking, to all income arising in the United Kingdom by whomsoever it may be enjoyed, and to all income accruing to persons residing in the United Kingdom without regard to the place where it may arise. The tax walks, so to speak, upon the two legs of origin and residence. It therefore leads to the problems of double taxation. Provisions for relief against this defect, resting upon the principle of division of the total tax between the two taxing jurisdictions, exist as respects income liable both to United Kingdom tax and tax in any of the British Dominions overseas, except in the case of the Irish Free State, where the relief is based upon the principle of charging tax only in the country of residence. Further provisions for double taxation relief also exist as respects profits on shipping. One code of laws applies, generally speaking, to individuals, partnerships, companies and other bodies of persons. In the main the tax is a tax on the incomes of individuals, nearly 90% of the total actual income brought into charge being distributed among individuals who are actually resident in the United Kingdom.

Administratively, the tax is levied under five separate categories or schedules of income. But this is a matter of machinery only, and the tax borne by individuals is in reality only one tax on the total income of the individual, and not, as is often thought, a series of taxes on the separate sources of his income.

Definition of Income.—In respect of the ownership of lands, houses, etc., in the United Kingdom, the measure of income is the annual value, which means broadly the rent at which the property is let, or is worth to be let by the year (the tenant bearing his usual rates and taxes), less certain statutory deductions for repairs, and an average cost of additional expenditure on repairs, maintenance, insurance and management.

In respect of the profits on occupation of land in the United Kingdom, the measure of profit is made on a conventional basis, which assumes profits bearing a fixed relation to the annual value of the land occupied. To-day that relation in the case of land used mainly for the purposes of husbandry is one of equality, and in other cases it is a relation of one-third of the annual value.

No definition is necessary in the case of interest on public funds. Income from dominion and foreign securities (other than public debts) or from foreign and dominion stocks, shares and rents is normally liable on the full amount of the income, less charges which must necessarily be met abroad.

There remain the two main classes: income from trades or professions and income from employments. Here the broad rule is that the income to be charged is the excess of the gross receipts over the expenses incurred wholly, necessarily and exclusively in earning the profits or income in question.

The British income tax, in the words of one of the judges, “ is a tax on income,” and this is strictly construed by the exclusion from the scope of the tax of profits which are in the nature of capital gains; and in this respect the British system is strikingly different from that in force in the United States of America. In consequence, the law prohibits, in arriving at profits for income tax purposes, any deductions in respect of capital charges, lost capital or losses unconnected with the business. Provision is, however, made for a deduction from the statutory profits liable to tax of an allowance in respect of the depreciation of machinery or plant.

Computation of the Statutory Income.—The amount of income liable to be taxed *for* any year of assessment (a year running from April 6 to the subsequent April 5) may be, but frequently is not, equal to the amount of income earned or received by the taxpayer *in* the year. This arises from the great variety of rules which govern the computation on various bases of the statutory income of different classes. For instance, income from trades and professions or from dominion and foreign stocks, shares and rents was charged on an average of the three preceding years. Employments and income from interest on public debts or from dominion and foreign securities are charged on the basis of the year of assessment. In other cases an average of five years is used. Proposals were, however, made to Parliament in 1926 for sweeping away some of this medley of different bases, and for substituting in the case of profits from trades and manufactures, mines, railways, iron works, gas works and water works, etc., and of income from dominion and foreign securities and possessions, a uniform base of the profits of the year preceding the year of assessment.

Differentiation.—More than a century of agitation passed before this feature of the income tax was established in 1907. At first it was effected by a reduction of the normal rate of tax in favour of earned income. To-day the differentiation is granted by deducting from the earned income an allowance of one-sixth of that income subject to a maximum deduction of £250.

Graduation.—This is the principle of levying a heavier percentage upon large incomes than upon small. From the inception of the tax graduation in some form or other has figured among its characteristics. During the last half of the 19th century graduation was effected on small incomes by a scale of abatements which from 1909 to 1918 was continuously developed and widened. To-day graduation is effected as follows:—

The total of the statutory income from various sources having been ascertained, the amount of any earned income allowance is deducted therefrom. From the balance, called assessable income, there is then deducted an aggregate of various personal allowances and deductions (*e.g.*, for self or self and wife, children, housekeeper, dependent relatives, etc.), leaving a balance constituting the taxable income. Tax is calculated upon this taxable income by charging the first £225 thereof at half the standard rate and the remainder thereof at the standard rate. From the amount of tax so arrived at there is deducted any relief, expressed in terms of tax, due in respect of life insurance premiums or dominion tax.

If the system of graduation stopped at this point, the relevant curve would rise steeply until incomes in the neighbourhood of £2,000 were reached, but after that point it would flatten rapidly. In order to continue graduation an additional duty of income tax called super-tax is charged on any individual whose total income from all sources for the preceding year, as computed for income tax, exceeds a fixed sum which stands at £2,000. For administrative reasons this additional tax is assessed and collected separately from income tax, but it is only a part of the scheme of graduation for the direct taxation of incomes exceeding a fixed amount. The super-tax therefore continues the process of graduation by imposing an additional rate of tax on successive sections of the total income above £2,000. The effect of this system as a whole is to levy an effective rate of tax on each £ of the total income of an individual, rising gradually from a fraction of a penny in the £ until the rate closely approaches a maximum rate represented by the sum of the standard rate of income tax and the highest rate of super-tax.

The following table of the amount of income tax and super-tax and the effective rate of tax per £ of income on specimen incomes clearly illustrates the graduation of the tax in the case of married couples without children for the year 1926–7. It shows how the effective rate rises in the case of earned income from 2d. in the £ for a total income of £300 by gradual stages up to 9s. 7½d. in the £ on an earned income of £150,000. The rate for unearned income rises from 2½ for an income of £250 to 9·7½ to one of £150,000. Plotted on a graph, these effective rates fall upon a very smooth line unbroken by any abrupt jumps.

Income Tax and Super-Tax

Married Couples without Children, 1926–7

Total income	If income all “ earned ” income					If income all “ inves ment ” income

Collection of the Tax.—Perhaps the most famous characte of the British tax is the principle of collection at the source. Seli has called it, “ perhaps the chief cause of the success of income It dates from as early as 1803. Under this principle the t obtained, whenever it is possible to do so, by deducting it befor income reaches the person to whom it belongs. The formal a ment is accordingly laid, wherever this course is possible, on source of income by itself and on persons who are debtors in re of income belonging to other persons. Power is given to the pa income to deduct the appropriate tax from the payments to the ultimate proprietors of that income. For instance, a li liability company is assessed to tax at the standard rate on the of its profits, without reference to their ultimate destination. paying interest to its debenture holders, or dividends to its s holders, the company is entitled to deduct and retain the amou tax appropriate to the interest paid or dividend distributed, an investor thus receives his interest or dividend subject to this de tion of tax. It is estimated that approximately two-thirds of the yield of the tax is collected at the source.

Whether the tax charged in respect of any income brought assessment is collected by deduction at the source or not thus pends upon the ultimate proprietorship of the income assesse far as the person charged is not the ultimate proprietor, the t collected by deduction at the source; so far as he is, the tax lected directly. The chief classes of income in respect of which tax is collected directly are the profits from trade of indivi whether sole or partnership traders; the like profits of limited ity companies so far as they are not distributed to shareho debenture holders, etc.; profits from the occupation of land; in from professions and most employments; income from dominio foreign securities and possessions not paid through agents i United Kingdom; income from certain interest, discounts, etc.

The income of individuals upon which tax is collected direc charged in the assessments, as far as possible, at the respectiv standard and full standard rates on the taxable income, that is the balance of the assessable income remaining after deduction personal allowances and deductions due. As the total income o individual taxpayer may be made up of a number of separate i on some of which tax is borne by deduction at the source at th standard rate, and on others of which tax is collectible dir adjustments are in numerous cases necessary in order to restri total tax payable to the amount proper to the actual circumsta of the individual concerned under the scheme of graduation differentiation already described. These adjustments are mad far as possible when dealing with tax collected directly, any bal being dealt with by repayment of tax. They are greatly facili by the fact that personal statements of total income are rend

ally by almost every individual taxpayer, for purposes of either
ne tax or super-tax.

th the exception of tax collected at the source on interest on
c debts and on income from foreign dividends, etc., which is
at or shortly after the time of payment of the income from
n the tax is deducted, income tax contained in the main assess-
s for the year is due and payable on or before Jan. 1 in the year
sessment; tax contained in additional assessments signed after
date is payable on the day after the date of signature. To this
al rule there are, however, some other important exceptions.
bulk of the tax charged on income from the ownership of prop-
tax charged on any individual or firm in respect of lands occu-
for husbandry, or tax charged on any individual or firm in re-
of a trade, profession or vocation, and of most employments, is
ble in two equal instalments, the first on or before Jan. 1 in the
of assessment, and the second on or before the following July 1.
vay companies in England and Ireland pay tax on their profits
ur quarterly instalments, on or before the 20th June, Sept.,
and March. Manual wage earners assessed half-yearly pay
n respect of each half-year. Tax in respect of employments
r the Crown is deducted (usually quarterly) at the source.

ministration.—In this sphere there is a striking division of
ority. The original basis of income tax administration is
elled to a certain extent on provisions in the Land Tax Acts of
8th century. The main conception in 1806, as well as in 1842,
that of a temporary impost to be assessed and collected locally
a minimum of interference by the Exchequer. The responsi-
for assessment and collection of a very large part of the tax was
upon the local bodies of Commissioners possessing certain prop-
or other qualifications. Benches of these local or district com-
oners were and are still appointed for certain cities and bor-
s and for parts or all of a geographical county. The individual
nissioners are entirely unconnected with and independent of
al control. Each body has its own clerk. The Commissioners
also empowered to appoint assessors of taxes and collectors of
s. Except as respects profits from commercial, financial and pro-
onal activities, the assessor was charged with making the assess-
of tax; in the case of the income arising from the activities
tioned this duty was laid upon a body of commissioners known
e additional commissioners. On the main body of the local or
ict commissioners distinguished by being known as the general
nissioners, fell the statutory duty of signing and allowing
sments made either by the assessor or the additional commis-
rs and of hearing and determining appeals against such assess-
s. Fitted into this scheme was the officer of the Crown, known
nally as the Surveyor of Taxes, and to-day as H.M. Inspector
axes. In law his part was primarily to safeguard the interests of
evenue with strictly defined rights of intervention and objection
rious stages of the formal procedure laid down by the statues.

en in the early years this broad scheme was honeycombed with
otions which have grown rather than diminished with the pas-
of years. Certain assessments for instance are hived off under
ingle jurisdiction of a body known as the Special Commissioners
come Tax, each of whom, still independent of the revenue
ority, is appointed by H.M. Treasury. This body performs all
luties of district commissioners in Northern Ireland; it makes all
assessments on railway companies and on their officials; the
sment of foreign and dominion dividends paid through agents
e United Kingdom is under its care; it is also solely charged with
whole of the administration of the super-tax. Then there are
nissioners for the various public departments of State who are
ged with making all assessments on official salaries, etc. The
k of England and the National Debt Commissioners also act as
missioners for assessment of individual salaries, etc., paid by
e bodies and those of the Bank of England are also responsible
he assessment of the profits of the bank. Again all assessments
nanual weekly wage earners which are for a half year only are
e by H.M. Inspector of Taxes. The taxpayer normally charged
he District Commissioners may, if he wishes, elect to be dealt
by the Special Commissioners and even if he allows his assess-
t to be made by the District Commissioners, he may take an
eal against that assessment to the Special Commissioners.

uring the past 50 years income tax grew so much in importance
complexity that its efficient administration compelled a con-
able development of the methods of administration. The high
uation of the tax rests very largely upon the factor of the total
me from all sources of the taxpayer. As business and finance
grown in complexity, the sources of individual incomes have
fied accordingly, necessitating close and continuous inter-
munication between various parts of the country. The scheme
dministration originally laid down having made no adequate
ision for inter-communication between the various bodies of
missioners, this defect has been almost of necessity filled by the
lopment of the official organisation of the Inspectorate of Taxes,
tioning under the direction of the Board of Inland Revenue. In
tice, therefore, to-day the Inspector of Taxes carries out, with
full concurrence of the various bodies of commissioners, most of
duties that are vitally essential to the smooth-working efficiency
e machinery of administration. Nevertheless, the key functions
e district commissioners have been preserved throughout. In the absence of any detailed accounts or other evidence, it is the additional commissioners who determine the amount of the assessment upon business profits; even more important, the general commissioners still retain their appellate functions and so stand in an independent and impartial position between the taxpayer and the representative of the revenue.

Rates and Yield of Tax.—During the three years preceding the War, 1911–3, the normal rate of tax was 1s. 2d. in the £ and the net produce of each penny of the rate was round about £3,000,000. At that time the exemption limit stood at £160 and out of some 19,000,000 of occupied persons only 1,200,000 were within this scope of the tax. In 1915–6, the exemption limit was reduced to £130. Notwithstanding the depreciation in the value of money it remained at that level until 1920. In 1920–1, when the system of differentiation and graduation was radically altered in accordance with the recommendations of the Royal Commission on the Income Tax of 1920, the effective exemption limit was raised to £135 of assessable income, or £150 in terms of earned income. Under the influence of the change in the price level and the consequential movement of wages the total number of individuals within the scope of the tax rose in 1919 to 7,800,000, but it had fallen in 1925–6 to 4,200,000.

The standard rate of tax was changed on six occasions between 1914 and 1925. The peak rate of 6s. in the £ stood for the four years from 1918–9 to 1921–2 inclusive. It was reduced to 5s. in 1922, to 4s. 6d. in 1923 and to 4s. in 1925. The statutory income of persons liable to tax amounted in 1913–4 to £951,000,000 and the net tax collected in that year amounted to £43,500,000. These figures relate to the whole of the United Kingdom of Great Britain and all Ireland. For 1924–5, the total statutory income of persons liable to the tax for the new United Kingdom of Great Britain and Northern Ireland was estimated at £2,300,000,000. In 1924–5 the Exchequer receipt was nearly £274,000,000; in 1925–6 the Exchequer receipt was £259,000,000 and it was estimated that the collection in 1926–7 would amount to £255,000,000.

The preceding figures relate to income tax alone and do not include the yield of the super-tax. Prior to the War the point at which liability to this tax commenced was £5,000. Incomes below that figure were exempt from this impost. In 1914 the exemption level was reduced from £5,000 to £3,000. In 1918–9 the scope of the tax was altered to include all incomes exceeding £2,500 and in 1920–1 further extension was made by the alteration of this limit to £2,000. Before the War the rate of super-tax was 6d. for every £ of the amount by which the total income exceeded £3,000, although, as noted, no liability arose unless the total income exceeded £5,000. A graduated scale was introduced in 1914–5, increased in weight in 1915 and 1918, until it reached the peak rates in 1920, when it ranged from 1s. 6d. in the £ for every £ of the first £500 of the excess over £2,000, to 6s. in the £ on every £ of income above £30,000. A reduced scale[1] of rates of tax came into force in 1925–6. In the year before the War only 14,000 persons were liable to this tax. In 1924–5, the number of individuals charged had risen to 90,000. A similar and even greater increase marks, of course, the annual yield of the tax. From £3,250,000 in 1913–4 the year's collection had grown to £68,500,000 in 1925–6. These figures may be completed by noting that during the 10 years from 1916–7 to 1925–6 inclusive, the British taxpayer paid £2,768,000,000 in income tax and £493,000,000 in super-tax, making a total of £3,261,000,000. This burden was borne in addition to £1,280,000,000 in the form of Excess Profits Duty and Corporation Profits Tax, each of which was levied upon business profits before the income tax and super-tax were due to be computed.

II. THE BRITISH DOMINIONS

Taxation according to faculty, that is, direct taxation based upon the principle of ability to pay, so early established in Great Britain, was naturally carried overseas to the various British possessions. It is not therefore surprising to find income taxes firmly established to-day in South Africa, in the provinces and protectorates there as well as in the Union, in Canada, where also there are provincial income taxes as well as the Dominion tax, Australia, where a similar widespread use of the tax is made, New Zealand, India and in most of the West

Indian islands. Naturally also there is a strong family resemblance between the various income tax systems, most of them having been strongly influenced by British law. Income is usually defined broadly but comprehensively, but there is a general absence of the schedular arrangement of the British tax. Broadly speaking, the year preceding the year of assessment is favoured as the basis of computation of the income to be charged. The minimum amount of income exempted from tax varies, but personal allowances to the taxpayer, his wife and children are general. Graduation of the tax is a common feature, and the device of an additional tax, or super-tax, is freely adopted. In some Dominions, graduation is extended also to companies. The methods of graduation range from simplicity to formulae of great complexity. Differentiation in favour of earned income is found, but is not widely favoured. Taxation at the source is a frequent feature, especially in respect of dividends paid by companies. The rates of tax vary widely, as may be expected from the range of budget requirements of communities of different populations and varying degrees of wealth. As a rule, the income tax in the British Dominions overseas is one tax levied upon the base of the total income, irrespective of the nature of the components of that income. In this respect, the British tradition is followed.

III. SOME EUROPEAN COUNTRIES

Latin Countries.—In Latin communities, a more complex system of income taxation is commonly found. There the development of the income tax as a fiscal instrument has been slower, and has met with much greater opposition. The influence of the ancient taxes in France of the real estate tax (*contribution foncière*), the door and window tax (*contribution des portes et fenêtres*), the business tax (*patentes*) and the personal property tax (*contribution personelle et mobilière*) led to the introduction by Caillaux, shortly before the World War, of an income tax, in the form of seven schedular taxes on income, combined with a general income tax on total income. Under this system, the schedular income taxes (*impôts cédulaires or impôts sur les revenus*) are but lightly linked together. Different rates may be, and often are, imposed under the several schedules; each schedule may have its own scale of personal abatements or reliefs; each may have its own rules for the computation of income. In France, the seven schedules cover buildings and land, agriculture, dividends, interest, etc. (again divided into four subgroups), industrial and commercial profits, salaries and pensions, professional earnings and mining. Each of the seven schedules has its own method of assessment, usually its own particular allowances, and its own special rate of tax. The general income tax (*l'impôt général sur le revenu*) is steeply graduated.

Belgium, on introducing an income tax into her fiscal system in 1919, followed the same method of schedular taxes combined with a general income tax. Here, there are three schedular taxes, on income from real property, income from investment of personal property and, lastly, income from trade business or profession or employment. Agricultural profits are included under the third schedule. For the first two schedules there is the same flat rate, but for the third, the rate of tax is graduated according to the amount of income. The general income tax is also graduated. In Spain and Italy similar systems prevail.

An income tax, designed to measure and to tax the almost infinite variations of methods by which men seek the means to satisfy their wants can never be simple, but the schedular system adds complexity to complexity. Moreover, so far as the rates of tax are differential, they tend to affect the ordinary incidence of an income tax, and so to set up reactions upon economic effort which defy measurement. There is also a strong tendency to regard the schedular income taxes, not as personal taxes but as real income taxes, a contradiction in terms which is at present proving a grave obstacle to the development of a satisfactory solution of the problem of double taxation.

IV. THE UNITED STATES

Although taxes on gains and profits derived from personal abi
as distinguished from property—so-called "faculty" taxes—w
employed in the American colonies before the middle of the
century, no successful use of the general income tax was made in
United States until the Civil War; and the income taxes then adop
were soon thereafter repealed, or fell into practical disuse.
demand for effective income taxation, however, showed great vi
ity. It kept moribund income tax laws on the statute books in
eral states; led to abortive experiments with the tax, particularl
the 'forties and 'nineties; and finally in 1909 resulted in the adopt
of a Federal excise tax "with respect to the carrying on or do
business" by corporations, equivalent to 1% of the annual net
come over and above $5,000. This proved to be in substance
effective income tax.

State Income Taxes.—In 1911 the State of Wisconsin adopte
general income-tax law applicable to individuals, partnerships
corporations. The practical success of this tax encouraged ot
states to adopt similar laws or to vitalise the administration of
successful income-tax laws already on the statute books; and
though a few states either repealed or rejected the tax, about
third of the states in 1925 had income taxes. The adoption of inco
taxes by the states has been largely for the purpose of replac
the unsatisfactory personal-property tax (particularly on intangi
personal property) and the so-called corporation franchise tax.
newer state income taxes are generally administered by state or c
tral authority, but provide for the return of a substantial portion
the tax to the county or local governments. There is an increas
tendency to assess the tax on the basis of the Federal income-
return and an effort is made by apportionment devices to exempt
whole or in part business or corporation income derived from pr
erty located and business transacted outside the state. Jurisdictio
questions and multiple taxation thus constitute fundamental p
lems. The various state income taxes differ considerably in th
exemptions and rates, but in general the rates are much lower th
in the Federal tax, the highest rates—in S. Carolina—being
third of the Federal rates. However, the combined Federal
State taxes represent a serious burden on the larger incomes.

Federal Income Tax.—The foundation for the Federal syst
of income taxation was laid by the ratification on Feb. 25 19
of the Sixteenth Amendment to the Constitution, which p
vides:—

> That Congress shall have power to lay and collect taxes on
> comes, from whatever source derived, without apportionme
> among the several states, and without regard to any census
> enumeration.

The development of the Federal income tax is suggested
the accompanying tabular statement. Under the Revenue
of 1926 the income tax carries exemptions of $1,500 for sin
individuals, $3,500 for heads of families and $2,000 for
porations. Under the personal income tax there is a furth
specific exemption of $400 for each child under 18 years and
every dependent incapable of self-support. Individuals
subject to a split normal tax of $1\frac{1}{2}\%$ on the first $4,000 of ta
able income, 3% on the next $4,000 and 5% on the remaind
and to a surtax ranging from 1% of the net income betwe
$10,000 and $14,000, to 20% on the net income in excess
$100,000. Corporations are subject to a flat rate of $13\frac{1}{2}$
(since Jan. 1 1926). Earned income (to the extent of $20,000)
taxed 25% less than unearned income, all incomes of $5,000
less being considered as earned. Net income is defined as
income and gains "from whatever source derived," excluding ce
tain specified classes of income and less certain specific deduction

The most important characteristic of the Federal income ta
is its striking productivity, the elasticity of which is illustrate
in the table. The present exemptions are high compared wit
similar exemptions allowed in other countries, and only a sma
proportion of the population is directly affected by the tax.
large proportion of the tax is collected in the industrial or urba
states and is thus marked by some unfortunate class and se
tional characteristics. Compared with similar taxes of othe
countries the rates on small and moderate incomes are low, whi
the rates on the larger incomes were until the year 1925 unusual

Returns reporting net income in excess of personal exemptions.

or net income of $5,000 and over, this exemption was reduced to $2,000.

. From the technical standpoint, the striking characteristics ie Federal tax are: The high ratio of surtax to normal tax; marked difference in the normal tax applicable to individ- and corporations respectively; the taxation of gains from occasional sale of capital assets, at a flat rate of 12½%; its re, largely because of constitutional limitations, to reach est on municipal bonds and other tax-free securities; the l use of "stoppage-at-source" (whereby the normal tax is held and paid direct to the government by payers out of nents due to corresponding payees); and the credit accorded ncome and profits taxes paid to foreign countries on income ved from sources therein.

he tax law is extremely complex, largely owing to the taxa- of capital gains and to certain "cushions" or relief pro- ons designed to protect the tax-payer against hardship; but law has been simplified in a measure by the repeal of the ss-profits tax and of many of the special war provisions such llowances for amortisation, inventory losses and the like. has been accompanied by a movement away from cen- sed administration of the tax, and by a steady reduction in rates. Nevertheless, complexity, centralisation and high ax rates still cause excessive delay in the audit of the larger rns. The interpretation of the law has been much improved he creation in 1924 of a Board of Tax Appeals (an extra- inistrative tribunal whose decision is final unless modified he courts), and by giving local revenue agents the power to t and settle the smaller cases. The American tax reveals a ual approach to the British position on capital gains and s, which are taken into account at a special rate of 12½%.

INDEX NUMBERS.—The phrase index number is sometimes applied to any series in which a chosen term is written as 100 and the other terms expressed as percentages of it. The earlier and more general use is, however, consonant with the following definitions:—"An index number [is] a number adapted by its variations to indicate the increase or decrease of a magnitude not susceptible of accurate measurement" (Edgeworth, *Economic Journal*, 1925, p. 379); "index numbers are used to measure the change in some quantity which we cannot observe directly, which we know to have a definite influence on many other quantities which we can so observe, tending to increase all or diminish all, while this influence is concealed by the action of many causes affecting the separate quantities in different ways" (Bowley, *Elements of Statistics*, 1920, p. 196). Thus index numbers are applied to the measurement of the *general* movement of prices, cost of living, wages, production, consumption, employment, etc.

The data from which index numbers are formed consist of records of particular quantities at two or more dates or places and information about the relative importance of these quantities in a general measurement. In constructing an index number to measure the movement of any defined magnitude it is necessary to decide on the choice of the separate quantities, on their relative importance, on the period or place to be taken as base, and on the formula of compilation. Thus, in the *Statist* index number the objective is the measurement of the change of wholesale prices in the United Kingdom, 45 commodities are selected and regarded as of equal importance, the period 1867–77 is taken as base and the average price in that period of each commodity is equated to 100, the terms in each series of prices are expressed as percentages of that average (" price-relatives "), and the simple average of the 45 relatives in any year form the index number for that year.

A distinction is drawn, but not by all writers, between two classes of index numbers: (*a*) where, as in the definitions quoted above, the object is to measure the movements of a magnitude without specific reference to any pre-determined application, *e.g.*, the purchasing power of money in general (" indice monétaire ") as conceived by Jevons, *The Variation of Prices and the Value of Currency since 1782* (1865); (*b*) where the measurement is to be applied to a defined group, *e.g.*, the changes in the cost of a quantitative standard, such as is used in a Cost of Living index (" indice budgétaire "). Many index numbers, however, are intermediate between these classes, and much of the analysis of the form and content of the numbers is appropriate to both. Thus, in all cases of price measurement, only those commodities can be included which are measurable in a defined and unchanged unit, and for which the price can be ascertained, and (unless the geometric mean is used) a base period in which each price is equated to 100 must always be selected.

(*a*) In the measurement of the purchasing power of money in general it is argued that the prices of all commodities, not subject to regulation or monopoly, are equally significant. Theoretically the problem is one of pure sampling, and the precision of the result in any year is directly proportional to the square root of the number of independent terms included and inversely proportional to the mean dispersion of these terms from their average in that year. In practice, the terms are not completely independent, for the prices of related commodities influence one another, and the precision is thus reduced. Also, the greater the interval from the base year, the greater tends to be the dispersion and the smaller the precision. In periods when prices are changing rapidly, as in the years 1914 to 1923, the dispersion is usually considerable and the measurement loses accuracy.

There are three types of averages applicable to price-relatives: their arithmetic mean as described above for the *Statist* index number; the geometric mean of the same numbers, that is the nth root of their product if there are n commodities; and the harmonic mean, which is the reciprocal of the arithmetic mean of the reciprocals. Thus, for two commodities whose prices were 6d. and 10d. in the base year, and 1s. and 2s. 1d. in any other year, the price-relatives are 200 and 250, their A.M. is 225, their G.M. is $\sqrt{(200 \times 250)} = 223{\cdot}6$, their H.M. is $1 \div \frac{1}{2}(\frac{1}{200} + \frac{1}{250}) = 222.2$ If the latter year is taken as 100, the relatives in the original base year are 50 and 40, the A.M. is 45, and 45:100 = 100:222·2. The H.M. of the " forward " relatives gives the same measurement as the A.M. of the " backward " relatives; or, if the comparison is between two places the H.M. of the relatives when the first is taken as base gives the same measurement as the A.M. when the second is so taken.

These statements are more readily expressed algebraically. Write $P_1, P_2 \ldots$ for the prices in the first year (or place), and $p_1, p_2 \ldots$ for the second. Write $100\frac{p_1}{P_1} = r_1 = A(1+d_1) \ldots$ where $A = \frac{1}{n}\Sigma v$ is the A.M. of the price-relatives.[1] Then $\Sigma d = 0$, the Geometric Mean, $G = \sqrt[n]{(r_1 . r_2 \ldots)}$ and

$\therefore n \log G = \Sigma \log A(1+d_1) = n \log A + \Sigma d - \frac{1}{2}\Sigma d^2 \ldots = n \log A - \frac{1}{2}ns^2$, approx. where s is the standard deviation of the dispersion of the relatives each divided by A, and mean d^3, etc., are neglected. Hence $A = Ge^{\frac{1}{2}s^2} = G(1+\frac{1}{2}s^2)$, approx. if s is small. Also the Harmonic Mean, $H = 1 \div \frac{1}{n}\Sigma\frac{1}{v} = nA \div \Sigma(1+d)^{-1}$

$\therefore A = H \times \frac{1}{n}\Sigma(1-d+d^2 - \ldots) = H(1+s^2)$, approx.

$\therefore H = G(1-\frac{1}{2}s^2)$, and $\sqrt{AH} = G$, approx.

Thus, if s is small A, H, G differ little from each other, b
$A > G > H$. If G is the correct measurement A exaggerates a r
and underestimates a fall (since $100 - A < 100 - G$), while H h
the opposite effect. The G.M. of A and H is very nearly
For the *Statist* index number in 1913 (1869–79 base perio
$A = 85{\cdot}0$, $G = 80{\cdot}9$, $H = 76{\cdot}5$, $s^2 = {\cdot}104$. As regards precision
sampling A may be written as $A\left(1 \pm \frac{s}{\sqrt{n}}\right) = A(1 \pm {\cdot}053) = 85 \pm 4$
if the 45 correlated entries are taken as equivalent to
independent (*Statistical Journal*, p. 316, Mar. 1926). In this ca
the standard error attributable to sampling is about the sa
as the difference between A and G.

A general change in the relation of currency to its use tends
affect all prices in the same proportion, and " if other disturbi
causes may be considered proportional to the ratio of change
price they produce in one or more commodities, then all t
individual variations of prices will be correctly balanced
against each other in the Geometric Mean " (Jevons, *Investi
tions in Currency and Finance*, 1884, pp. 121–2; see also Bowl
Economic Journal, 1921, p. 202). The Geometric Mean is the
fore considered appropriate to this problem. It has the a
vantage that it gives less importance to extreme measuremen
than does the Arithmetic Mean. It has the further advanta
that the comparison by its use of any two years is independe
of the choice of the base year (*see* below).

(*b*) The method generally used in the more objective proble
of measuring the change of cost of a fixed aggregate of goods is
follows: The quantities of defined commodities which are p
duced or consumed in a year, or exported or imported, or a
purchased in a week by a family, are estimated and the pric
per unit are ascertained in a base year or period and also in t
year to which the measurement is to refer. This budget
quantities is valued at the base year prices and again at the pr
of the year in question; the latter total expressed as a p
centage of the first gives the required index number. The co
putation is often effected by writing down the relative expe
ture (quantity × price) on each commodity in the base ye
applying to each the percentage that its price in the seco
year forms of that in the first, and adding the products. T
sum (divided by the total of the base year's relative expen
itures) gives the same index number as before. Cost of Livi
index numbers are computed by this method. In this form t
index number appears as a " weighted average," where t
weights are the relative expenditures and the things weighted a
the price-relatives. From the theory of weighted averages it
known that considerable roughness in the weights has litt
effect on the result. It may also be regarded as an averag
price-relatives which form a sample of a larger group than th
included, and therefore—as under (*a*)—its precision depen
on the square root of the number of independent relatives an
inversely, on their dispersion about their average.

Write $Q_1, Q_2 \ldots$ for the number of units of quantities, P_1
$\ldots$ for the prices in the base period, $p_1, p_2 \ldots$ for those in the ye
in question. Then $E_1 = Q_1P_1 + Q_2P_2 + \ldots$ is the total expenditu
in the first year, and $E_2 = Q_1p_1 + Q_2p_2 + \ldots$ is the total expen
ture in the second year. Then the index number is $I_1 = 100E_2 \div$ I

Now write $Q_1P_1 = l_1E_1$, $Q_2P_2 = l_2E_1 \ldots$, with $l_1 + l_2 + \ldots =$
Write $100p_1 = r_1P_1$, $100p_2 = r_2P_2 \ldots$, so that $r_1, r_2 \ldots$ are the pri
relatives. Then the new index number is $l_1r_1 + l_2r_2 + \ldots$
$(Q_1P_1r_1 + Q_2P_2r_2 + \ldots) \div E_1 = 100(Q_1p_1 + Q_2p_2 + \ldots) \div E_2 =$
The weighted Geometric Mean, $G_1 = \sqrt[n]{(r_1^{n_1} r_2^{n_2} \ldots)}$ whe
$n_1 + n_2 + \ldots = n$, so that $n \log G = n_1 \log r_1 + n_2 \log r_2 + \ldots$ T
English Board of Trade, for its index number of wholesale price
uses a similar form in which, if for example n_1 is the weig
assigned to cereals, $r_1^{n_1}$ is replaced by ${}_1r_1 \times {}_2r_1 \times \ldots$ to n facto
where ${}_1r_1, {}_2r_1 \ldots$ are price relatives of n_1 different quotations
cereal prices. When $n_1, n_2 \ldots$ are once chosen the compariso
between any two years A and B is independent of the base yea

---

[1] Such an expression as Σv is to be read $v_1 + v_2 + \ldots + v_n$ where n is the number of similar terms.

f the price ratios for the years are written ${}_{a}r_1$, ${}_{a}r_2$ . . . and ${}_{b}r_2$ . . . and G_a, G_b are the resultant means, then log $\frac{G_b}{G_a}=$ $G_b-\log\ G_a=n_1(\log {}_{b}r_1-\log {}_{a}r_1)+n_2(\log {}_{b}r_2-\log {}_{a}r_2)+$ . . . log ${}_{ab}r_1+n_2 \log {}_{ab}r_2+$ . . . , where ${}_{ab}r_1$, ${}_{ab}r_2$ . . . are the ratios ie prices of the year B to those of the year A, and the prices he base year do not enter. If with similar notation the ımetic average is used, we have $A_b \div A_a=(n_1\cdot{}_{b}r_1+n_1\cdot{}_{b}r_2+$ $\div(n_1\cdot{}_{a}r_1+n_2\cdot{}_{a}r_2+$ . . .), in which no corresponding elimination s place.

ıe weakness of this method is that, when we make a comıon between two years or two places, the relative expendis generally differ and each scheme appears to have an equal ı to be included. This difficulty may be met theoretically by ›uting the index twice, first with the expenditures in year or A and then with those in B and averaging the result. comparison between places this method is applied, but it ldom that the necessary "weights" can be obtained for than one year, and till there is a further census of proion or a new collection of working class budgets the double ›utation cannot be made. Further, if the weights are availfor three years or places, A, B and C, the index for B in ence to A multiplied by that for C in reference to B does not ny weighted average formula give that for C in reference to ·100), as it should. This so-called "condition transitive" is ıatisfied by any formula that is symmetrical with regard to hts.

rite ${}_{a}Q_1$, ${}_{a}Q_2$ . . . and ${}_{a}P_1$, ${}_{a}P_2$ . . . for quantities and prices and ${}_{b}Q_1$, ${}_{b}Q_2$ . . . , ${}_{b}P_1$, ${}_{b}P_2$ . . . in B. The "forward" index ber is $I_a=100\Sigma_a Q_1\cdot{}_{b}P_1\div\Sigma_a Q_1\cdot{}_{a}P_1$ and the "backward" number is $I_b=100\Sigma_b Q_1\cdot{}_{b}P_1\div\Sigma_b Q_1\cdot{}_{a}P_1$. The Geometric ı $\sqrt{I_a\times I_b}$ is Prof. Irving Fisher's "Ideal index number" *Making of Index Numbers*, 1922, p. 220). The arithmetic ıge, $\frac{1}{2}(I_a+I_b)$ and the form $I_2=100\Sigma\frac{1}{2}({}_{a}Q_1+{}_{b}Q_1)\cdot{}_{b}P_1\div$ $Q_1+{}_{b}Q_1)\cdot{}_{a}P_1$, may be conveniently used. The three forms ıerage may be expected to give nearly identical results. which the quantities at the two dates are averaged, is perthe simplest in idea. Each average lies between I_a and I_b, s greater than I_a if an increase of prices of a commodity the general increase from year A to a later year B is cored with a relative decrease of the quantity purchased, as may pected if there is a possibility of substitution of one comty for another without any general change of standard ley, *Statistical Journal*, 1919, pp. 343 *seq.*).

their measurement of the change of Import or Export index from year A to the consecutive year B, the Board of Trade the formula I_b and for comparison with the next year C ormula $100\times\frac{\Sigma\,{}_{b}Q_1\cdot{}_{b}P_1}{\Sigma_b\,Q_1\cdot{}_{a}P_1}\times\frac{\Sigma\,{}_{c}Q_1\cdot{}_{c}P_1}{\Sigma\,{}_{c}Q_1\cdot{}_{b}P_1}$ which does not equal $\frac{{}_{c}Q_1\cdot{}_{c}P_1}{{}_{c}Q_1\cdot{}_{a}P_1}$ obtained by direct re-valuation of the C quantiıy the A prices and, if there is a very rapid change of quanand prices, may differ considerably from it. This is an ple of the "step-by-step" or "chain" method of index ›ers. Note that from A to B, $100\frac{\Sigma\,{}_{b}Q_1\cdot{}_{a}P_1}{\Sigma\,{}_{a}Q_1\cdot{}_{a}P_1}$ is an index ›er of quantity of trade (prices constant), and $100\frac{\Sigma\,{}_{b}Q_1\cdot{}_{b}P_1}{\Sigma\,{}_{a}Q_1\cdot{}_{a}P_1}$ index number of value of trade. The product of these ırements of price and quantity is the index of value (× 100). ce no form of index number satisfies all the conditions can properly be laid down (see *e.g.*, Gini, in *Metron*, 1924, ı and 134), on the one hand we must select the form most l for a particular purpose, on the other we can only expect ion when different relevant forms give approximately ıme result, for which the conditions are that the dispersion ces from their average should be small and the number of tuent elements should be considerable. *See* COST OF G: PRICES. (A. L. Bo.)

EX SYSTEM: *see* OFFICE APPLIANCES.

INDIA (*see* 14.375).—The fifth regular census of the Indian Empire (March 1921) gave a total population of 318,942,480, of whom 247,003,293 dwell in British India, and 71,939,187 in the Indian States. The corresponding figures of area were 1,805,332 sq. m., of which 1,094,300 lie in British territory, and 711,032 in the Indian States. With an area rather more than half that of the United States, the country has a population about three times as large. But the increase in population, 1.2% during the decade 1911–21, was the lowest in any similar period since the decennial census was instituted:—the result of a widespread failure of the crops through drought in 1918, and an epidemic of influenza which is estimated to have carried off anything up to 10,000,000 victims.

Political Divisions.—British India consists of (*a*) nine major or "Governor's" provinces, viz.: Assam, Bengal, Bihar and Orissa, Bombay, Burma, Central Provinces and Berar, Madras, Punjab and United Provinces of Agra and Oudh; (*b*) two minor provinces, viz.: Baluchistan and the North-West Frontier Province; and (*c*) certain smaller administrative areas, viz.: Ajmer-Merwara, Andamans and Nicobars, Coorg and Delhi. The present article deals exclusively with British India, except where the contrary is stated.

The Indian states are governed by ruling princes and chiefs, and are in political relation with the British Government through the medium of political officers specially attached to the larger units or groups. The rulers of 119 states have a salute of guns, which forms a rough measure of their relative importance, as it varies from 21 guns to 9; the remaining 442 states and estates have no salute. Many of the smaller estates are divided up among several sharers. The more prominent individual states are Hyderabad, Mysore, Baroda, Kashmir and Gwalior; and apart from these units the main territorial groups of states are Rajputana, Central India, the Western India states, the Punjab states and the Madras states. Burma contains a number of Shan states, which technically form part of British India, though they are administered through their hereditary chiefs.

Religions, etc.—A classification by religions would divide every 1,000 of the people into 686 Hindus, 217 Moslems, 37 Buddhists, 31 Animists, 15 Christians, 10 Sikhs and 4 Jews, Parsees and followers of other faiths. The census recorded 22,600,000 as literate, in the sense of being able to write a letter in their own vernacular tongue; and 2,500,000 were returned as able to read and write English. Seventy-one per cent of the people are supported by agriculture, 1% only by organised industry, another 9% by the simple hand industries, 7% by trade and transport, 1½% by the professions and liberal arts, and 1½% by the administration and protection of the country.

I. GENERAL HISTORY

Lord Hardinge as Viceroy.—In the spring of 1910 the appointment of Lord Kitchener to succeed Lord Minto as Viceroy seemed probable. Fate reserved Lord Kitchener for other tasks, and the choice fell on Sir Charles Hardinge, permanent Under-Secretary for Foreign Affairs and formerly ambassador at St. Petersburg, who was raised to the peerage as Lord Hardinge of Penshurst. His long viceroyalty (Nov. 1910–March 1916) was strenuous and eventful. The earlier years were marked by the visit of King George V. and Queen Mary to India, the selection of Delhi as the site of the future capital of the Indian Empire, the revision of the "partition" of Bengal and the nefarious attemps of anarchists to compass the deaths of the Viceroy and his wife on the occasion of their state entry into Delhi. The closing years saw India in the throes of the World War.

Lord Hardinge, like his predecessor, had an hereditary connection with India, as his grandfather, the 1st Viscount Hardinge, was Governor-General (1844–8) in the stirring times of the first Sikh War. The goodwill of Indians towards the new Viceroy deepened as they saw his genuine liking for their country; his zeal to obtain redress of the grievances of Indians residing in other parts of the Empire; and his endeavours to associate their political leaders with the work of government under the reformed Councils scheme. His diplomatic and Foreign Office experience and knowledge of the politics and conditions of the East enabled him to handle dexterously and effectively the external affairs of India and to enter into the difficulties and apprehensions of Indian Mahommedans. He cordially pursued the policy of friendship and co-operation with the ruling chiefs of native States that Lord Minto had inaugurated. When the World War came in 1914, the popularity of his administration and the personal influence and friendship which he had acquired with the ruling princes had much to do with the magnificent response of India to the call of the Empire.

The Morley-Minto Reforms.—The scheme of administrative reform which had been worked out between Lord Minto and Lord Morley, then Secretary of State for India, was in full operation when the new Viceroy arrived. The main object of the India Councils Act, 1909, had been to enlarge the Legislative Councils and make them more fully representative, introduce the elective principle, give greater powers of discussion and of obtaining information from the executive. In each Council the nominated members comprised: (1) a substantial *bloc* of officials, the *bloc* in the Imperial Legislative Council being large enough to secure, together with the members of the Executive Council, an absolute majority; (2) non-officials nominated to represent classes or interests which would otherwise be unrepresented or inadequately represented.

In all the councils, with the exception of that of Bengal, the nominated members exceeded in number the elected members. The number of the latter in any province was too few to admit of any system of territorial constituencies and direct voting. Special constituencies therefore were formed, such as universities, chambers of commerce, groups of municipalities and district boards, and also for Mahommedans as a separate class or community. The councils were empowered to discuss and move resolutions on the annual budget and in like manner to raise discussions by resolution on matters of general public interest. But they did not vote the budget, and resolutions operated only as recommendations which were not binding on the Government. The councils had no direct control over the executive, though they could inform and influence it; Lord Morley had emphatically said that India was not ripe for parliamentary institutions and that he would be no party to creating them. The Act increased the number of members of the executive councils of Madras and Bombay from two to a maximum of four, thereby providing a seat for an Indian or two Indian members; it also authorised the creation of an executive council in any province having a lieutenant-governor. The policy of associating Indians with the executive government thus affirmed as regards to provinces, was given effect to in the Government of India by the appointment first of Mr. S. P. (afterwards Lord) Sinha, and then of Sir Ali Imam as Law Member of the Governor-General's executive council.

Working of the Reforms.—Lord Minto had predicted that the conciliatory measures embodied in and associated with these changes would clear the political atmosphere. He prophesied rightly. On Jan. 5 1911, a deputation from the Indian National Congress presented an address to the new Viceroy expressing deep and heartfelt loyalty to the Crown and appreciation of the reforms which " had done much to bring about a better understanding between the Govt. and the people. " As the enlarged Legislative Councils settled down to their work, even the advanced party found in the new powers a healthy outlet for their energies. As consultative and critical bodies the reformed councils exercised a real and growing influence and were an educative force. They formed, directed and developed public opinion in political matters. They acted as a restraint upon the autocratic tendencies of the Executive and made it more responsive to popular demands, and they strengthened its hands when it had to sustain Indian interests against the interests of Great Britain or of the self-governing Dominions.

The King's Visit.—The royal visit in the winter of 1911 was a complete success. The presence of the King-Emperor and his Consort in India touched the imagination of the people. Delhi ceremonies drew vast crowds eager to see and salute sovereign. When a visit to Calcutta followed, the welc given by the populace of that city was even more enthusia and unrestrained. On Dec. 12 1911, in a great arena out Delhi specially prepared for the occasion, the King held a c nation durbar at which he received in person the homage of great officers of state and the ruling princes and chiefs of Indian Empire. Largesse and “ boons ” of various kinds granted, and an announcement made of great political mom The seat of the Govt. of India was to be transferred from cutta to Delhi; Eastern Bengal was reunited to Bengal and enlarged province given a Governor in Council; Bihar, Or and Chota Nagpur, tracts which are loosely connected Bengal proper were made a Lieutenant-Governorship in Cou and Assam was reformed into a chief commissionership. secret had been well kept, and the surprise was complete. scheme, though open to obvious objections was ingenious cleverly balanced. A reasoned exposition of its object is tained in a despatch, dated Aug. 25 1911, from the Govt India to the Secretary of State, submitting the proposed cha for the home Govt's approval in advance of the King's visi

Time alone will test the wisdom of these changes, autoc cally conceived and dramatically carried out. The buildin the new capital was thrown back by the World War, and cost, which was originally estimated at £4,000,000, will gre exceed that amount. New Delhi, it is urged by opponents of scheme, will be merely cold-weather headquarters of an off hierarchy, an imposing mass of buildings untenanted for matic reasons during eight months of the year; while the G of India, rotating between it and Simla, will live perpetually bureaucratic atmosphere. On the other hand the drawback Calcutta were many, and constitutional changes have empha the desirability of removing the supreme Govt. from imme contact with the internal administration of Bengal. The p dential Government of reunited Bengal is an undoubted suc the bitterness of feeling engendered by the “ partition ” has appeared, and the interest of the Mahommedan populatio the Eastern districts receives a just measure of attention the local Government. The province of Bihar and Orissa is weak feature of the scheme. The artificial union of two bl of territory, geographically apart and without linguisti racial affinities, can never be a convenient administra unit.

Lord Hardinge's internal Administration.—The beginning sustained advance in popular education was made at the D coronation durbar, at which a recurring grant of 50 lakhs (£ 000) to local Govts. for the purpose was announced. This followed in succeeding years by larger grants. From 1911–5 recurring grants amounting to £3,250,000 and recurring gran £826,000 were made to the provinces. The total annual exp iture on education rose during the period by nearly £3,000 and the number of boys and girls at school or college by 1,500, This expansion was numerically greatest in the primary sch A wide educational policy was laid down, embracing the uni sities and secondary and technical schools and colleges. search and post-graduate instruction were promoted in universities. A well-equipped medical college was establi at Lucknow, raising the number of medical colleges in Indi five, schools of tropical medicine were founded in Calcutta Bombay, and an institute of science at Bangalore. Non-recu imperial grants for public health service, amounting to £2, 000, and recurring grants of £368,000 were made, rendering ticable the execution of sanitary measures which a few years fore seemed beyond the limits of financial possibility. appointment of a royal commission under the presidency of Islington, to inquire into and report on the public services of with a view to increasing the proportion of Indians in the hi offices was warmly approved. Another popular measure was establishment of a Legislative Council in the Central Provi

Indians in the Dominions and the Colonies.—Serious content was provoked by the position of indentured labo colonies to which it was permitted, and by the treatment ndian residents in South Africa and Canada. The first ble arose over the refusal of the Natal Govt. to accept n immigrants as permanent citizens of the Union after the ation of their indentures. As no redress was obtained the t. of India in 1911 prohibited for the future indentured ration to Natal. In the following year the grievances of ndian domiciled in the Union against the Union Govt. came head. The Indian settlers resorted to "passive resistance." situation was aggravated by strikes and riots among an labourers in Natal. Intense feeling was aroused in India ports of the treatment of passive resisters by the magistrates he rough handling of strikers and rioters by the police. In eech delivered in Madras (Nov. 24 1913), Lord Hardinge essed evident sympathy with the passive resisters in their gle against "invidious and unjust laws," and pressed for quiry in South Africa by a strong and independent com- e on which Indian interests should be fully represented. e Union Govt. resented the Viceroy's language, but the lated indiscretion served its purpose. A commission of iry was appointed, and a solution was at length reached and died by the Union Govt. in its Indian Relief Act, 1914. closed the passive resistance struggle. In the action took Lord Hardinge's Govt. had the warm approval of the ated classes. With regard to Canada the grievances of ns were less easy of settlement, and Lord Hardinge only advise a policy of reciprocity, which could be made tive without direct retaliation and would not raise questions e personal status of Indians in Canada.

volutionary Crime.—A new and sinister feature in Indian ad forced its way to the surface soon after Lord Minto ed in the country. The wide-spread unrest, which he found g the educated classes, and endeavoured to appease by ical reforms, had its echo among other classes which were eated by economic discontent and with whom crude ns of self-rule and political freedom easily "yoked them- s," as Lord Morley put it, "to deep invisible roots of race, creed and inviolable caste." Secret societies, com- chiefly of young men belonging to respectable families, g up in many districts of Bengal, having for their object eliverance of India from the foreign yoke. This they t to compass by assassination and terrorism. The art of -making was imported from Europe. Revolutionary liter- and the use of pistols and explosives were sedulously ed, and a series of anarchical crimes occurred from 1907–9. roup of measures were passed for dealing with seditious meet- publications and associations, and for establishing special dure and special tribunals for the trial of anarchical crime. was apparently restored; but in Bengal trouble broke out towards the close of 1912; and by the end of 1913 the ordi- forces of law and order in that province had been definitely n. On Dec. 23 1912, as the Viceroy was making his first entry into Delhi, a bomb was thrown and exploded in the *ah* of the elephant on which he and Lady Hardinge were g, severely wounding him and killing an attendant. The ants were never brought to justice, but there is little t that they were connected with the anarchical movement in al which had extended to the Punjab. In 1914 and 1915 rev- onary activities became more daring, with the assistance erman agents in America and the Dutch East Indies; but igorous use of the special powers provided by the Defence dia Act broke up the movement for the time being and ed order. The organisation of the revolutionary societies, inter-connection and propaganda methods, their success in pting the educated youth of the country, are minutely ibed in the report of the Sedition Committee (1918) over Mr. Justice Rowlatt presided.

THE WAR PERIOD

lia's Effort.—On the outbreak of the World War in Aug. the response made by India to the needs of the Empire was testimony of her pride in the British connection. The political leaders instinctively suspended their controversies with the Government, and gave her their support. The martial classes eagerly responded to the call to arms. From the rulers of native states lavish offers of help poured in. They were recounted in the Viceroy's telegram to the Secretary of State, dated Sept. 7 1914, which was read in both Houses of Parliament and circulated throughout the Empire. As a wonderful demonstration of loyalty and generosity, its effect on popular feeling was immense.

With this confidence and enthusiasm were mingled some alarm and bewilderment. Trade came to a standstill. There were runs on the banks, encashment of currency notes and hoarding of coin. In the remoter districts rumours of the Collapse of the British *raj* disturbed the countryside. The Mahommedan peasantry in parts of the Punjab raided and burned the houses of Hindus and moneylenders, and military force was required to restore order. In Bengal the revolutionary societies redoubled their criminal activities. In San Francisco and Vancouver an Indian revolution was openly preached to the Sikhs settled there, and numbers of them were incited to return to the Punjab to take part in a general rising. Their designs were detected, but for some months the Punjab was disturbed by murders, dacoities and robberies, and the reckless use of arms and explosives.

India as a whole however was so calm that the Govt. was able to denude itself freely of its military resources to meet the demands of the home Govt. for troops and war material. Most of the British troops, the flower of the Indian army, the best of the artillery, and large quantities of ammunition were despatched to France and other theatres of war. In Sept. 1914 a force of 70,000 men was sent to France. By the end of 1915 India's contribution amounted to nearly 80,000 British and 210,000 Indian officers and men. At one time the original British garrison was reduced to only 15,000 men. These were gradually supplemented by territorial and garrison troops from home, but throughout the War the British element in the army in India was far below the defensive needs of the country.

The entrance of Turkey into the War placed Indian Mahommedans in a difficult position; but they loyally rallied to the side of the Crown. Against a few prominent agitators only was it necessary to take action. The premier Mahommedan prince, the Nizam of Hyderabad, and the Begum of Bhopal, in addresses to their co-religionists, effectively stated the British case, and exposed the falsity of the pretexts by which Enver Bey and his associates sought to justify the entrance of Turkey into the War. These addresses and a declaration by the Govt. of India as to its attitude towards Islam in general and the Holy Places in particular served greatly to maintain tranquillity.

Retirement of Lord Hardinge.—In Nov. 1915 Lord Hardinge completed his fifth year as Viceroy, but at the request of the home Govt. remained in office until the following April. In a farewell speech to his Legislative Council he expressed his wish to see "the early realisation of the just and legitimate aspirations of India," but he besought his hearers not to be led astray by impracticable ideals, but to look facts squarely in the face and to realise that in the Dominions self-government had been the slow product of steady and patient evolution.

Lord Chelmsford's Administration.—Lord Chelmsford, the new Viceroy, assumed office on April 4 1916. Previously Governor of Queensland and of New South Wales, at the time of his appointment he had been serving as an officer with a territorial battalion in India; and he was cast at once into one of the most difficult periods of British-Indian history, momentous alike in the number and magnitude of the problems demanding solution and in the gravity of the issues they have raised. In the very first year of his administration the political peace enjoyed by his predecessor came to an end. In the early part of the year Mrs. Besant succeeded in getting her scheme of Home Rule considered by leading members of the National Congress and the Moslem League. She continued to advocate it with great energy among students and school-boys in Madras, established a Home Rule League, celebrated a "Home Rule" day, and declaimed in her paper *New India* against the Government. Mr. B. G. Tilak, who up to 1914 had been serving a sentence of six years' imprisonment for sedition, was equally active in Bombay. In Oct. 1916, a group of elected Indian members of the Imperial Legislative Council submitted a memorandum on proposed reforms to the Govt. of India. They described the Morley-Minto reforms as having created Legislative Councils which were mere advisory bodies without any effective control; they propounded a scheme which, while retaining irremovable executives responsible to Parliament and the Secretary of State, would have subjected them in legislation, finance and administration, to the orders of a legislative body in which elected members would be predominant.

At meetings held in Lucknow in Dec. 1916 the National Congress and the Moslem League agreed upon a scheme of reforms as the irreducible minimum with which the National party would be content. The Moslem League, originally founded for the protection of Moslem interests against Hindu ascendancy, had fallen under the influence of the "young" Mahommedans, who made Home Rule their objective and joined forces with the Congress on the condition that in certain provinces in which the Mahommedans were in a minority they were guaranteed a proportion of seats in the future Legislative Councils in excess of the number they could hope otherwise to win. Effect was given to this compact, henceforth known as the "Lucknow Compact," in the Congress-League scheme. Following the Lucknow conferences an energetic Home Rule campaign was opened in all provinces. The stir in the Nationalist camp was quickened by the knowledge that the views of Lord Chelmsford's Govt. on political reforms had for some time past been before the home authorities. A preliminary and informal examination of the changes possible and prudent had been made by Lord Hardinge. Lord Chelmsford immediately on assuming office took up the inquiry from the point where his predecessor had left it. At the close of 1916 his government submitted to the Secretary of State a considered scheme of reforms, and asked for an authoritative declaration of policy. Was the goal for the Indian peoples to be responsible government? If so, by what stages and steps should it be reached? The questions raised were large and delicate. The Cabinet was preoccupied by the War. In July 1917 the Secretary of State Mr. (Sir) Austen Chamberlain, resigned on the report of the Mesopotamian Commission.

Declaration of Aug. 20 1917.—It fell to his successor, Mr. E. S. Montagu, to announce on Aug. 20 1917, in the House of Commons, the Indian policy of the government.

> The policy of H.M. Govt. is that of increasing the association of Indians in every branch of the administration and the gradual development of self-governing institutions with a view to the progressive realisation of responsible government in India as an integral part of the British Empire . . . . Progress in this policy can only be achieved by successive stages. The British Govt. and the Govt. of India, on whom the responsibility lies for the welfare and advancement of the Indian peoples, must be the judges of the time and measure of each advance, and they must be guided by the co-operation received from those upon whom new opportunities of service will thus be conferred and by the extent to which it is found that confidence can be reposed on their sense of responsibility.

In the course of the winter Mr. Montagu visited India, and a joint report, dated April 22 1918, by himself and the Viceroy was drawn up before he left.

War Conference of 1918.—The Montagu-Chelmsford report was nearing completion when attention was recalled to the pressing realities of the War. In the Near East, German troops had penetrated the Caucasus and Turks were invading Persia. With the collapse of Russia, the opening up of a road to Afghanistan and thence to India seemed possible. In a telegram (April 2 1918), the Prime Minister made an appeal to the Govt. and people of India to redouble their efforts and prevent German tyranny from "spreading to the East and engulfing the world."

Lord Chelmsford's reponse was to convene a War conference at Delhi, to which many ruling princes and representatives of all provinces of every shade of opinion were invited. The conference heartily and loyally responded to the appeal, and agreed upon a programme of measures of no small value. In the five months preceding the Armistice 200,000 men were recruited, and
had the War gone on this number would have been great
creased. In the spring of 1917 the Legislative Council ha
cepted the Govt's. proposal to make a free gift of £100,00
to the home Govt. towards the expenses of the War. Thi
in addition to the obligation the Indian Govt. had under
of bearing the normal charges of all troops on the Indian
lishment sent overseas. The part borne by India in the Wa
the sacrifices made by her people for the common cause ar
resented by an addition of over 230 crores of rupees (£153
000) to her debt, the sending overseas of 800,000 combatant
400,000 non-combatants, and the furnishing of foodstuff
other supplies at the cost of much privation among the
classes. If the agriculturists as a body and some other se
of the community made money out of the War, the urban
and the multitude of persons on small salaries and fixed in
suffered greatly from the dearness and scarcity of foo
clothing.

India After the War

Reception of Montagu-Chelmsford Report.—The Armisti
Nov. 1918 was the signal for general rejoicings but ushere
season of political strife and agitation unfavourable for the
ful introduction of the new constitution. The Montagu-Ch
ford report had been published in the previous July. In the
session of the Legislative Council the report was re
for consideration to a committee of the non-official me
and was approved by them, with certain qualifications.
moderate party held a special conference in Nov. at Bo
and accepted the general principle of the Montagu-Chelm
scheme, while urging that it should be enlarged in certain
On the other hand the National Congress, which ha
become the organ of the extreme national party, wholly
demned the scheme at its Dec. meeting, demanded ful
vincial autonomy at once, and asserted India's right to
determination. Unhappily another controversy now
which was fated to overshadow and prejudice the con
tional question by the passions which it kindled an
bitterness which it imported into the relations of the
and the Government.

The Rowlatt Bill.—The report of the Sedition Com
over which Mr. Justice Rowlatt presided had discusse
outbreaks of seditious crime, particularly from 1907, an
provided impressive evidence of the existence of a revoluti
and anarchical conspiracy in Bengal and elsewhere and the
fectiveness of the ordinary criminal law to deal with it.
Committee proposed to strengthen in certain minor re
the existing law, and to endow the Governor-General in C
with emergency powers, to be used only in specified areas
only after a notification declaring the existence of a state of
in those areas which demanded emergency measures.
measures included: (*a*) the trial of seditious crime by three
of the highest status, without juries or assessors who were
to be affected by public discussion or deliberate terrorism
(*b*) the investing of a provincial Government with powe
internment similar to those conferred under the Defence of
Act, but modified by checks in the shape of local investig
and visiting Committees. In Jan. 1919 the publication o
draft bills embodying the Committee's proposals was foll
by a violent campaign by the Nationalist press and Natio
politicians. They were represented as an attack upon the
lar liberties, an attempt to invent crimes, a monstrous engi
tyranny and oppression, the forerunner of a policy of rea
and an unmerited slur upon the loyalty and law-abidingne
the Indian people. A whirlwind of excitement swept throug
cities of upper India, a strange medley of ignorance and
of political unrest and domestic discontents, of conscious
geration and mendacity.

While the bills were before the Legislative Assembly, M
K. Gandhi, a well-known social and religious reformer, re
in the Bombay Presidency as an ascetic and holy man, initi
a passive resistance movement. *Satyagraha*, as he terme
meant insistence on truth and a reliance on soul force. O

latt bills receiving the Viceroy's assent, Mr. Gandhi an-
nced a day of general mourning and cessation of business.
March 30 a *kartal*, or closure of shops, took place at Delhi,
mob came into collision with the police, and deaths occurred.
ave of excitement passed over the Punjab. Violent disturb-
s broke out in Lahore, Amritsar and other centres when
s came that Mr. Gandhi had been forbidden to enter the
vince and had been sent back to Bombay under arrest. Be-
n April 10 and 15 mobs were in possession of these and
r towns in the central Punjab. Disorder assumed the char-
r of open rebellion, definitely anti-government and anti-
ish, communications were cut, and the civil authority was
maintained by military force. Martial law was proclaimed
mritsar on April 14, was extended subsequently to other dis-
s and was not finally withdrawn from every part of the Prov-
until June, although order was generally restored by the
of April. But the situation remained critical owing to the
ian War, and it was thought prudent to run no risks.

Bombay the news of Mr. Gandhi's arrest at Delhi was the
sion of an immediate outbreak of disorder in Ahmadabad,
capital of Guzerat, and in neighbouring towns. The military
to be called in, but not before numerous acts of incendiarism
violence and some loss of life had occurred. The disturbances
inated on the arrival of Mr. Gandhi, who expressed great
ow at the excesses of his followers and was allowed to address
normous meeting at which he upbraided the people for their
ence.

mritsar.—On April 13 " the tragedy of Amritsar " occurred.
hat city banks and other buildings had been pillaged and
it and Europeans murdered. The civil officers, finding them-
es powerless to cope with the mobs in possession of the city,
d upon the military to restore order. Brigadier-General Dyer,
officer commanding, deemed it necessary in the course of his
ations to disperse forcibly an unlawful assembly held in the
inwala Bagh. Nearly 400 persons were killed by the fire of
roops, and probably thrice that number wounded. His ac-
aroused intense indignation among Indians of all shades of
ical opinion, and became the subject of most bitter contro-
y, which was in no wise allayed by the appointment towards
end of the year of the Hunter Committee to inquire into the
disturbances which had arisen in consequence of the Row-
legislation. General Dyer's action was condemned by this
mittee, and it was decided by the authorities that he should
ive no further employment in India. After a warm debate in
House of Commons (July 8 1920), this action was approved
30 votes to 129, but the House of Lords, on July 20, by 129
s to 86, passed a motion "deploring" the treatment of Gen-
Dyer as " unjust " and as "establishing a precedent dan-
us to the preservation of order in the face of rebellion." *The*
ning Post, taking this view, raised a considerable sum as a
monial to the censured officer. In June 1924, the case came
the law courts in London. Sir Michael O'Dwyer, who was
enant-governor of Bengal at the date of the Amritsar affair
ight an action against Sir Sankaran Nair, formerly member
he viceroy's council, whose book *Gandhi and Anarchy* had
ibuted to him a responsibility for the shooting. Sir Michael
wyer won the action, receiving £500 damages, and the judge,
Justice McCardie, expressed the view " that the time and
method of General Dyer's punishment, if he were wrong,
most unfortunate."

he Afghan War, 1919.—Relations with Afghanistan had been
ormly good ever since the Amir Habibullah's visit to Lord
to in 1908. He had been received in state at Agra on Jan. 9
iat year, and afterwards went to some of the principal cities
idia and made a prolonged stay in Calcutta. The Amir was
hted with his reception, and let it be known that his friend-
with the British Govt. had been immensely strength-
. During the World War he was staunch; but on Feb. 20
, he was murdered, and his son Amanullah ascended the
ne.

ie succession was disliked by powerful factions in the state;
in his difficulties the new Amir lent an eager ear to the distorted reports of the disturbed state of the Punjab and of the nature of the Rowlatt Acts which found their way to Afghanistan. He concluded that an invasion of India might prove a solution of his domestic differences, appealing as it would to the religious fanaticism of his Mahommedan subjects, deeply stirred by the humiliation and defeat of Turkey and by the British conquest of Mesopotamia. His plan was to incite the independent tribes to rise and to follow up their raiding parties with his Afghan regular forces. But the frontier tribes were slow to move. Aggressive movements of his troops in the Khyber were countered by the rapid mobilisation of the army in India early in May, the occupation of the Afghan advanced base at Dacca and the bombing by aeroplanes of Kabul and Jalālābād. By the middle of May the Afghans asked for a cessation of hostilities, and in June the Amir accepted an armistice. In July his representatives attended a conference at Rawalpindi and on Aug. 8 a treaty of peace was signed, under which the Amir lost his subsidy and the privilege of importing arms through India. A separate letter officially recognised the freedom of Afghanistan from foreign control. Doubts have been expressed as to the wisdom of this concession. But control over the foreign policy of Afghanistan has always been nominal rather than real, and the withdrawal of the subsidy in itself implied the rescission of the reciprocal obligation.

Waziristan Expedition.—The Rawalpindi Treaty did not end the troubles on the frontier. The independent tribes of Wazirs and Mahsuds, who occupy a large block of country south of the Khyber line between Afghanistan and the British districts to the east, had risen in May at the instigation of the Afghans and raided the adjoining British districts. The Indian Govt. determined to undertake the permanent pacification of the country, a serious undertaking, as the tribes could place some 30,000 well-armed men in the field. A strong force was assembled on the frontier in Oct. and an ultimatum given to the tribes. The Wazirs in the Tochi Valley were soon subdued, but the Mahsuds fought with dogged obstinacy and great skill. There were two considerable encounters (on Dec. 21 1919 and Jan. 14 1920) with heavy British casualties. In the end the Mahsuds accepted the terms imposed upon them, and the military operations closed on May 7 1920.

The Non-co-operation Movement.—In Dec. 1919 the Montagu-Chelmsford scheme of constitutional reform became law by the passing of the Govt. of India (Amendment) Act. The King's proclamation of Dec. 23 dwelt in eloquent and arresting language on the political advancement conferred upon the Indian peoples, authorised the Viceroy to extend the royal clemency to political offenders in the fullest measure compatible with the public safety, and announced that the Prince of Wales would visit India to inaugurate the new constitutions. The effect of these gracious words was unfortunately marred by the excitement which attended the inquiry of Lord Hunter's Committee then in progress into the Punjab disturbances of the preceding April. The National Congress met at Amritsar, and passed resolutions denouncing the Government's action in the Punjab, demanding the recall of Lord Chelmsford and condemning the reform scheme as disappointing and unsatisfactory. This hostility towards the administration and rejection of the reforms by the extreme section of the Nationalists developed in the ensuing months into a definite " non-co-operation " movement organised by Mr. Gandhi.

The publication in 1920 of the report of the committee presided over by Lord Hunter, and of the correspondence between the Govt. of India and the Secretary of State regarding its findings, and the subsequent debates in Parliament renewed the bitterness and indignation which the Amritsar proceedings had aroused in India. About the same time the terms of the Sèvres Treaty became known to Indian Mahommedans and added flame to the " Khilāfat " agitation, which the pro-Turk section of that community had been vigorously fomenting. In Aug. Mr. Gandhi proclaimed in a letter to the Viceroy his adoption of non-co-operation as a remedy against a Government for which he retained " neither respect nor affection " on account of its " unscrupulous, immoral and unjust" action in the matter of the Caliphate and its failure to punish adequately the officials responsible for "the wanton cruelty and inhumanity" with which the disorders in the Punjab were suppressed.

In Jan. 1921 the Duke of Connaught visited India in place of the Prince of Wales, and inaugurated the new constitutions. The speeches delivered by him in opening the Legislative Assembly, the Council of State and the Chamber of Princes at Delhi and the Legislative Councils of Madras, Bengal and Bombay made a deep impression. His earnest appeal, as an old friend of India, to all parties, British and Indian, "to bury along with the dead past the mistakes and misunderstandings of the past," struck a note which found response in the proceedings of the new legislatures and in the Indian Press.

On April 2 1921 Lord Chelmsford made over the office of viceroy to his successor Lord Reading. No viceroy had been more tried by circumstances beyond his control, and no viceroy had shown more steadfast courage, patience or devotion to the highest ideals of his great office. The era will be a landmark in the history of modern India. It saw India started on the road to self-government and admitted on equal terms to a partnership in the British Empire. (T. W. Ho.)

THE NEW CONSTITUTION

During Lord Chelmsford's viceroyalty an important change had taken place in the political machinery. The Morley-Minto reform had introduced the electoral principle into the Indian legislatures, and given them a wider sphere of influence over the executive government. But in effect they remained advisory bodies, and the absence of any administrative responsibility whetted their critical faculty without giving them any corresponding practice in the actual work of government. The executive authorities, imperial and provincial, remained governments of officials, responsible to the Secretary of State, and through him to the British Parliament, and not amenable in any direct sense to popular control in India.

From this arrangement to the announcement of Aug. 29 1917 was a wide step, involving organic change and not taken before time. The enthusiasm which had welcomed the Morley-Minto reform had long evaporated, and the demand by the Indian leaders for administrative power was insistent. The Montagu-Chelmsford report conceded the justice of the demand, and proposed that responsible government, in the sense of government by ministers primarily responsible to an elected assembly, should be conferred on India by progressive stages. It recognised that India was not yet ready for full responsible government, that an electorate had to be created and that its representatives must at first be inexperienced. Its authors proposed therefore to confine the first stage of advance to the major provinces, and in these provinces to set up a dual form of government, generally known as "diarchy." This device, accepted only after all possible alternatives had been found impracticable, was a division of the provincial field of government into two sections, one of which would be transferred to the control of ministers chosen by the Governor from the elected members of his legislative council.

In July 1919 a bill embodying this scheme, with certain modifications, was introduced into the House of Commons, read a second time and referred to a joint select committee of both Houses presided over by Lord Selborne. The committee, after an elaborate investigation and hearing nearly 70 witnesses, accepted the main principles of the scheme, and dealt at length with the political and administrative problems involved in the bill. Their report (H.C. 203) is a most valuable constitutional document, indispensable to a study of the new régime. The bill passed both Houses substantially as amended by the committee, and received the Royal Assent on Dec. 23 1919. It takes the form of amendments of the Government of India Act, and has been so drafted as to admit of its being textually incorporated into the principal Act. As is usual with statutes relating to India, it left a great deal of the new constitution to be worked out by rules drafted and applied by the Government to meet the needs of each particular case.

Demarcation of Spheres.—If its provisions were taken in l
sequence, the first feature of the new Constitution would
demarcation of the duties of the "central" or Imperial
from those of the provincial Governments. The former r
certain powers of supervision and control over the prov
administrations; but its direct functions are now specif
listed, and the departments which are under the prov
Govts. are similarly enumerated. These Governments
their revenue from the departments under their own
trol, *i.e.*, land revenue, stamps, excise, forest, etc. The Im
Govt. takes the yield of its own central departments—rail
post and telegraphs, customs, income tax, salt, opium, etc
present, however, these do not balance its budget, which c
the whole cost of the defence of India; and consequently i
to levy subsidies from the provinces, though it is pledged to
go them when the development of its own resources shall pe
As with the administrative and financial powers, so also ar
law-making powers of the central and the provincial autho
carefully delimited.

The Provincial Sphere.—Each of the major provinces is
placed under a Governor. The whole of the provincial de
ments are divided in each province into two groups, the
served" and the "transferred." The former (at present la
order, justice, police, the land, etc.) are administered b
Governor and his executive council (of whom at least one
ber is an Indian); the latter (education, public health, excise,
are administered by the Governor and two or more Mini
who are chosen by him from among the leaders of the prov
legislature. These two bodies work independently, each i
own field; and their responsibilities are clearly distingui
The Governor is the link of union, and has full discretion to
them together for joint consultation on matters of con
interest. The Executive Council in its control of reserved
jects, is responsible through the Govt. of India and the Secr
of State to the British Parliament; the Ministers in their co
of transferred subjects are responsible to the legislative co
on the spot. This, in the briefest terms, is the system which
been named or nicknamed "diarchy." Its purpose is to pr
a field of actual duty in which Indian leaders can be train
actual practice in the art of Government. On the one hand,
will have the assistance of the Governor, and opportunit
consulting their official colleagues in the executive council
the other hand, the field entrusted to them will be car
defined, so that their work can be seen and judged by the
torate, and so also that any consequences of their inexpe
may not affect the sphere of administration which remains i
hands of the executive council.

The legislative council in each province has a large el
majority, with an element (under 30%) of officials and nomi
members. The elections are direct and the constituencies
ly territorial. A property qualification, differing in diff
provinces, determines the franchise. The vote has been giv
about 5,000,000 of the adult male population in the wh
India, female suffrage being left to the local option of the p
cial councils. For whatever legislation and supply they req
both halves of the Government are dependent on the legisl
thus constituted. In the "transferred" sphere, Ministers
secure the support of the legislature. If they fail, their
fails; and the ordinary course is for them to resign or be dism
by the Governor, so that they may be replaced by Ministers
can carry the legislative council with them.

In the "reserved" sphere, it is the task of the Govern
his official colleagues to reconcile the legislature to their p
But if they fail, their responsibility for right policy to the B
Parliament is in no wise diminished; certain safeguards
accordingly provided against the event of the council refus
law or supply for which it has been asked by them. The Go
or has an exceptional power to pass such a law by his own d
if he certifies that it is essential for the discharge of his resp
bility; but a measure enacted in this way has to be rese
for His Majesty's pleasure. Similarly the Government m
store a grant for expenditure which has been refused or red

the council if the Governor certifies in the same sense; and ase of emergency he may authorise any expenditure which ay be in his opinion necessary for the safety or tranquillity he province or for the carrying on of any department." Fi- y, should the legislature take action in any department which Governor regards as dangerous, he has wide powers to stop a or to refuse assent to it, or to return it for reconsideration, or :eserve it for the consideration of the Governor-General. ensive safeguards thus exist against the possible misuse of its er by the provincial legislature.

he Imperial Sphere.—In the central Government there o diarchy. The Governor-General and his Executive Council whom there are now in practice not less than three Indian nbers) still remain in sole and undivided responsibility to iament for the supreme Govt. of India. The central legisla- , however, has been radically altered by the 1919 Act. Lower House, or Legislative Assembly, has 144 members, 103 whom are elected direct by constituencies similar to those ch elect to the provincial legislatures but larger in area and a higher property qualification. In the Upper House, or ncil of State, are 60 members, of whom 33 are elected on a more restricted franchise. In neither Chamber therefore is e an assured majority for the Government, to secure the s, the taxation measures or the expenditure grants which it iires for the administration of the country. The underlying ception of this unusual situation is that it should throw the ernment more upon the support of the elected representa- s of the people and weaken its reliance on the direction of the etary of State. It was anticipated that, where the Executive t. and its legislature are in accord on policy, there would be a vention of non-interference by the Secretary of State, subject ourse always to the overriding power of the British Parlia- t. It was not, however, unforeseen that the Central Govt. not always be able to carry the legislature with it, and ma- ery was provided for avoiding a deadlock in such an event. legislative business a difference between the two Chambers be referred to a joint sitting. If in either Chamber a bill is osed or amended so as to affect "the safety or tranquillity ritish India or any part thereof," the Governor-General may it. He may also, as under the previous constitution, veto a or refer it for His Majesty's pleasure. Should he recommend l which either Chamber accepts and the other rejects, he may t it as enacted; or if both Chambers reject it, he may make it an Act on his own responsibility. In both cases, however, the ernor-General must first have certified that the "passage of bill is essential for the safety, tranquillity or interests of ish India or any part thereof," and the measure must subse- ntly be laid before both Houses of Parliament; effect may be given to it, unless in a state of emergency, until His Maj- 's assent has been received. In financial business the supply nts have to be voted by the Legislative Assembly; but if a nt which the Governor-General declares to be essential to discharge of his responsibilities is refused or reduced, he may ore it. Expenditure on defence and in the political and ec- astical departments, charges prescribed by law, loan charges certain salaries and pensions need not be voted; and the ernor-General has power to sanction vital expenditure in s of emergency.

urther Development.—The above is an outline of the complex me that comprises the first stage in what the preamble of the Act describes as "the gradual development of self-govern- institutions." As "the time," to quote the Act again, "and manner of advance can be determined only by Parliament," provided that, 10 years after the passing of the Act, a Par- entary Commission will go to India, to inquire into the work- f the reforms, and to report on the desirability of establish- the principle of responsible government, or of extending, ifying or restricting the degree of responsible government ady existing. In other words, the retention or otherwise of electoral system and diarchy will be examined on the evi- e of the work actually achieved; and it will be decided, if chy is retained, whether further departments should be transferred from the official half of each provincial Government to the control of Ministers. It has been necessary to recite the main features of the new constitution because of the influence they exercised on the political history of Lord Reading's viceroyalty.

LORD READING'S VICEROYALTY 1921–6

Arriving in April 1921, the Earl of Reading brought to the office of Governor-General a prestige not exceeded by that of any of his forerunners. Having served as Law Officer of the Crown, Cabinet Minister, Lord Chief Justice of England and British High Commissioner in the United States, he enjoyed an eminence both as a lawyer and as a statesman which made his selection a particular compliment to India. The task which confronted him required all his courage and all his experience. Though the actual machinery of the new constitution had begun its work with relative smoothness, the country was seething with an excitement for which the political changes were merely a pretext. A moderate section of Indian leaders commanded the Councils and furnished ministers to the provincial Governments. But they owed their position to the boycott of the whole scheme by the extremist politicians, whether Hindus or Moslems, who had taken no part in the elections of the previous winter, and now held no place in the Councils or the Ministries. The real battle of India's future was being fought outside the domain of constitutional Government.

Hindu Extremism.—The more advanced Nationalist party were gaining strength and audacity under the magnetic leadership of Mr. Gandhi, who had been appointed virtual dictator of their forces at the National Congress of Christmas 1920. He was sweeping the country with his cry of non-violent non-co-operation. The yoke of foreign dominion was to be thrown off and the curse of western commercialism eradicated. India would then be worthy of complete Home Rule, and a date (at first Sept. 30 1921, but subsequently extended on several occasions) was actually prophesied for the disappearance of the British Government. In his campaign Mr. Gandhi was aided by bands of "national volunteers," pledged to deliberate lawlessness, and carrying the spirit of unrest from the towns into the rural areas. Outrage after outrage showed the inability of the masses to distinguish between non-co-operation and anarchy. The tide of disaffection was rapidly rising, and the jails could no longer contain the volunteers who courted a tolerable martyrdom. The condition of the country had not been worse since 1858.

Mahommedan Extremism.—Moslem feeling also had been growing in acerbity for several years. Long persuaded that it might rely on the special consideration of the British Govt., it had been rudely shocked by the reversal of the partition of Bengal in 1911, for the severance of Eastern Bengal into a separate province had been regarded as a measure for the protection of the large and impoverished Moslem community in that area. Genuine distress was felt at the misfortunes of Turkey in Tripoli (1911–2) and the Balkans (1912–3); and among the younger men a movement of active sympathy with the "Young Turk" party made considerable headway. When the Sherif of Mecca revolted against his Turkish overlords it was not only the young Indian Moslems who condemned his action, or resented the part which they were convinced that Great Britain had played in fomenting it. Though there was very little active disloyalty during the war, and although the cooler heads among the Indian Mahommedans disapproved the action of Constantinople in siding against Great Britain in the World War, an under-current of religious solidarity was stimulated by economic discontent and a lively sense of the waning of the power of Islam.

The Treaty of Sèvres was attacked as a device of England to humiliate her former friend and ally; and a movement of protest was headed by two brothers, Mahomed Ali and Shaukat Ali, whose liberty had been restrained for seditious agitation during the War. Their followers were known as the Khilāfat party from their claim that the temporalities of the Sultan, as Khalifa of Islam, should be restored. With them there was no pretence of non-violence; they attempted to seduce the Mahommedan troops, played on religious fanaticism and talked of proclaiming an Indian republic. Seeing in them a useful adjunct to his own campaign, Mr. Ghandhi took the Khilāfat movement under his wing. It was in a struggle against this combination of forces that the first three years of Lord Reading's Govt. were mainly spent.

The Moplah Rising.—In Aug. 1921 the most serious of many unpardonable deeds of violence broke out. The Malabar country in Madras is occupied by 2,000,000 Hindus and about 1,000,000 Moplahs, an ignorant Mahommedan peasantry of mixed Arab and Indian descent with an evil reputation for outbreaks of fanaticism. Among the latter the Khilāfat excitement spread like wildfire; and during July and Aug. 1921 meetings were held and arms collected to prepare for the coming of an Islamic millennium and the overthrow of British rule. When the magistrate of Calicut attempted to make some arrests, he was met by armed force, and rebellion immediately broke out. Railway and telegraph lines were cut, roads blocked, Government offices burned and a Moplah king proclaimed. The few Europeans who failed to escape from the district were brutally murdered, and then the Moplahs turned upon their inoffensive Hindu neighbours. They burned villages, sacked temples, outraged women, massacred and attempted wholesale the forcible conversion of the Hindus to Islam. The extraordinary difficulties of the country made the task of suppression particularly difficult; and the troops which were locally available had to be reinforced at the beginning of Oct. by four battalions, a pack battery and a section of armoured cars. A drive was then made through the affected area, and the rebellion gradually collapsed. It is estimated that during the campaign the Moplahs lost 3,000 in killed alone.

The whole tragedy was a definite fruit of the extremists' challenge to law and order. It was also the first shattering blow to the Hindu-Moslem unity which the extremists had hoped to establish for their own purposes; Mr. Gandhi and his lieutenants professed to belittle the outbreak, but it soon became apparent how gravely the Moplah atrocities rankled in the minds of the ordinary Hindus. Meanwhile the Ali brothers had got to the end of their tether. In Oct. 1921 they were arrested, tried at Karachi and sentenced to two years' imprisonment. But the Khilāfat agitation was not now to be checked, and it soon gained fresh momentum.

Visit of the Prince of Wales.—On Nov. 17 1921 H.R.H. the Prince of Wales landed at Bombay for the visit to India which had been postponed in the preceding year. Efforts, partly successful, but frequently defeated by the Prince's arresting popularity, were made to boycott the public ceremonials arranged in his honour; yet the tour was courageously carried through. He rapidly traversed British India, carried through a heavy tale of ceremonies and interviews, visited several of the leading Indian States, as well as Nepal, inspected the northwest frontier, attended the Kadir Cup (pig-sticking meet) near Meerut, and finally left for England from Karachi in March. The just comment on results of the tour is a quotation from the Viceroy's telegram to the Prince on his departure: "You leave India having won India's heart, for the road to the heart of the people lies through knowledge and sympathy. From the day you landed in India you set yourself to gain the one; Providence has endowed you with the other."

Decline of Non-co-operation.—The year 1921 marked the apogee of the extremist movement, and among moderate men of all classes it was felt that the Govt. of India was approaching the limits of permissible patience. Mr. Gandhi was preparing a scheme of mass civil disobedience, both aggressive and defensive, and was on the eve of launching it, when on Feb. 4 1922 another hideous outrage occurred. At the Chauri Chaura village, in the east of the United Provinces, 21 policemen and village watchmen were set upon by a mob of "volunteers" and excited peasants and battered to death or burned alive. Mr. Gandhi at once suspended his orders for civil disobedience, issued a new "constructive programme" which threw his followers into confusion, but he was at last arrested on March 10 1922. Put on trial at Ahmadābād on three charges of spreading disaffe and instigating the overthrow of the Government, he ple guilty and was sentenced to six years' simple imprisonn His trial produced no popular excitement. It was overshad by the resignation by Mr. E. S. Montagu of his office as S tary of State, as a sequel to his having published, without net approval, a dispatch from Lord Reading's Govt., in w His Majesty's Govt. was urged, in deference to Mahomm sentiment in India, to revise the Treaty of Sèvres.

The cause of non-co-operation now began to waver. The unteer movement was collapsing from want of funds. Mr. dhi's repeated prophecies of the millennium had been falsi The Nationalist schools which had been started to rival the ernment institutions had been failures, and masses of stud saw their careers imperilled. Nor was the boycott of the maintaining its popularity among the lawyers who abound Mr. Gandhi's camp. The unity of Hindu and Mahomm action was severely shaken by the numerous outbreaks of r violence. Above all, good harvests were steadying the ma and economic discontent was being allayed. By the end of a strong section of the Nationalist party wished to reverse policy of holding aloof from the councils.

The Akali Riots.—The unsettlement, however, which Nationalists had engendered, was no longer theirs to curb, took little heed of political manoeuvres. It had now penetr the slow-moving Punjab, and the doctrine of non-violent struction to authority was bearing strange fruit on unlikely For some years there had been a reforming movement among Sikhs, directed at recovering a number of scattered temple their religion from hereditary incumbents (Mahants) and ploying their revenues for the spiritual service of the people erally. The puritan reforming section (Akalis) had got into habit of taking the law into their own hands, and ejecting violence the Mahants of whom they disapproved. The appealed to the courts, or engaged armed retainers to de their property. In either case it was necessary for the Gov ment to intervene; and it suited the employers of the A bands, adherents of the non-co-operation movement, to dis this intervention into hostility against the Sikh religion. attempts by the Government to bring the Akali fervour orderly channels were frustrated, and in 1922 the Akalis es lished such a reign of terror that military assistance had t supplied to the police.

Then came the episode of the Guru-ka-Bagh, one of the extraordinary stories of recent Indian history. At a small te 10 miles from Amritsar the police had prevented some A from trespassing and cutting trees; whereupon from all ove Punjab bands of Sikhs assembled to assert their right over land. The method they employed was bewildering in its de ture from the usual martial spirit of the Sikh. A band of A volunteers started every morning from Amritsar, under a to employ no violence but to reach the temple or to return s less. The police who were deputed to protect the property w obliged to use their batons (in India, their *lathis* or iron- bamboo staves) sufficiently to stun the volunteers, who were t carried trimuphantly back to Amritsar in the ambulance which their sympathisers had in readiness. This demonstra went on day after day, until the whole Sikh community was i ferment and its traditional loyalty to the Government was but destroyed. In 1923 the animosity of the Sikhs was tu against the administration of the Nabha State, the Mahara which had abdicated rather than face an inquiry ordered b Govt. of India. Regrettable incidents occurred; but the fu of the whole business at last began to dawn upon the S mind, and by the end of 1924 common sense was reassert itself.

It was not only in the Punjab that 1924 and 1925 were diffi years. Moslem feeling was very bitter about Great Brita treatment of Turkey. Susceptibilities were set on edge by Greek invasion of Asia Minor, and subsequently elated by victories of Mustafa Kemal. Either emotion had a tenden bring the Moslems into conflict with their Hindu neighbou racial tension again became acute in the latter half of 1922. following two years were thus marked by an almost continu- succession of sporadic disturbances in Northern India.

cond Phase of Lord Reading's Viceroyalty.—At the end of came the second general election. A strong section of the gress Party, adopting the label of Swaraj (Home Rule), e away from Mr. Gandhi's programme of boycott and put up ass of candidates for the councils. The Liberal or Moderate y, which had predominated in the first triennium of the new latures, were attacked as having supported the Government lstering up an unpopular constitution. They had also lost sion and discipline, and a new party, describing itself as pendent, but standing on no common platform, made serious ads on their position. For the Swarajists the election was a tantial victory. They secured nearly half the elected seats e Central Assembly; and in at least two of the provinces they manded the provincial councils. Their discipline was good, they had entered the legislatures with the avowed object uniform, continuous and consistent obstruction with a view ake Government through the Assembly and the Councils ossible." It was only in the central provinces, however, that proceeded at once to extremes, rejecting the budget pro- n for the salary of Ministers, and ultimately compelling the ernment to resume the "transferred" subjects and suspend operations of diarchy. In the central legislature, which first after the elections on Jan. 31 1924, they concentrated on de- ding that the grant of full responsible government should be dited. When this was not endorsed by the Government, retaliated, in coalition with a sufficient number of members he other parties, by rejecting the Finance bill for the year, the result that the Viceroy had to use his emergency powers certify the necessary expenditure of the administration. episode, however, and the subsequent conduct of the Nation- Coalition during the remainder of the session, established n in the rôle of a constitutional opposition, thus marking w stage in the political development of the country, so that second phase of Lord Reading's viceroyalty may be taken as ng from Jan. of 1924.

he last prop of non-co-operation was knocked away when, special summer session of the legislature, the Swaraj party d with the Government on a tariff measure; and Mr. Gandhi, had now returned to politics, threatened to lead his followers of the National Congress into a campaign of social reform and du-Moslem unity. Of the latter the prospects were gloomy, the tale of racial conflicts and bloodshed was ever length- g. The culminating outbreak occurred at Kohat in Sept. 4, and ended in the whole of the Hindu population fleeing n the town. A unity conference, hurriedly got together at hi, though attended by representative members of all the ian communities, ended in little but good resolutions. Equally fective was an attempted coalition of all the political parties he councils; but Mr. Gandhi was won back to the Congress p, and the opening of 1925 found the Swaraj party temporari- n a position of considerably improved strength. In Bengal, oting their policy on opposition to an ordinance which the ernment published against a recrudescence of revolutionary ne, they refused for a second time to vote salaries for Minis- , with the only result that the Governor in Executive Council imed control of the transferred departments and diarchy for me was at an end. But in the Central Assembly the policy of cking took second place to a growing divergence between the Independent party and the Swarajists.

he Muddiman Inquiry.—In the autumn of 1924 an important uiry into the working of the new constitution was held by a mittee under the presidency of Sir Alexander Muddiman. appointment was in response to the demand by the National- politicians for the early abolition of diarchy in favour of some n of provincial autonomy. Its business was to advise on any ects in the working of the 1919 scheme and on any amend- ts compatible with the general purpose and structure of scheme. The report (published as cmd. 2,360 of 1925) was wofold one. A minority of the members found that the new system had broken down, that transitional measures were inappropriate, and that steps should at once be taken to establish a permanent constitution. The majority on the other hand recorded their opinion that, though the experiment had worked too short a time to justify a final verdict, they were not convinced that it had failed. They recommended several minor improvements in the machinery and procedure; but they concluded that, "except by some form of dualism, it was not possible to afford an equally valuable training towards responsible government in India and still to safeguard those conditions upon which government depends." The Swaraj claim that responsible government should be expedited was by implication rejected.

While the controversy which followed the publication of the Muddiman report was running its course, Lord Reading accepted an invitation from the Secretary of State for India (now the Earl of Birkenhead) to visit England for the purpose of personal discussion in the summer of 1925; the Governor of Bengal, Lord Lytton, officiating as Viceroy in his absence. This was the first exercise of a new Act enabling viceroys and provincial governors to obtain leave during their term of office. It was obviously desirable to announce a line of policy in answer to the protestations of the Nationalists that the 10-year period of experiment should be curtailed, and that the British Parliament ought not to impose its judgment as to the fitness of India for self-government.

On July 10 accordingly Lord Birkenhead made a careful statement in the House of Lords, reviewed the working of the Reform Act of 1919, and emphasised the lack of co-operation and the actual hostility displayed by a section of the Indian leaders. He expressed his willingness to consider any practical scheme of advance on which Indians could agree, and he did not close the door to an antedating of the statutory inquiry due in 1929, if Indian leaders gave evidence of a sincere and genuine desire to work the present machinery. On Aug. 20 a corresponding speech was made by Lord Reading in opening the autumn session of the Indian legislature, coupled with a plea for a closer co-operation. This did not avail to dissuade the Assembly from rejecting the advice of the Muddiman Commission; but when, in the same month, the Chamber had for the first time to elect its own president, its choice fell on Mr. V. J. Patel, who accepted the office and solemnly dissociated himself from all parties, although he had been formerly one of the most advanced non-co-operationists in the Swaraj camp.

Regrouping of parties was the keynote of the caucus meetings at Christmas 1925. The die-hard Swarajists flung an ultimatum at the Government, with threats of civil disobedience, obstruction and the refusal of office; and over this the Congress split. A new wing of the party, representative mainly of western India, broke off and declared for a policy of "responsive co-operation." At a separate conference the Liberals prepared a separate platform; so did the Independents; and a powerful gathering of Moslems at Aligarh assented to a definite anti-Hindu propaganda. The united front which political India had seemed to present in 1921 was seriously disintegrated by 1926; but the processes of schism and reunion are never at an end.

Administrative Progress.—Although political excitement during Lord Reading's viceroyalty seriously hampered the daily routine of administration and often went near to paralysing the legislatures, yet the administrative system was too firmly rooted to be rendered fruitless. In the provinces the output of legislation was abundant; and in the Central Assembly measures of much importance were painfully hammered out, notably in the removal of racial privilege, in establishing a protective fiscal system, and in meeting problems of organised labour which were for the first time emerging in India. The rural community, it is true, were left the Cinderella, as well as the catspaw, of political advance; but Lord Reading sufficiently appreciated their dominant importance to procure, on the eve of his departure, the appointment of a royal commission to go into the whole question of agriculture. Fortunately there had been steady advance in agricultural prosperity. A short monsoon in 1920 necessitated considerable famine-relief operations in the succeeding year; but thenceforward a series of remarkably good harvests lowered prices and restored the contentment of the masses. The epoch of economic distress in 1920–1 had affected the manufacturing classes even more than the patient agriculturists. Labour trouble came to the front as never before, 1921 witnessing no fewer than 400 strikes of varying magnitude, and legislative measures of a new type began to appear on the statute book.

Social Organisation.—An amended Factory Act in 1922 prescribed a 60-hours week and raised the minimum age of child workers from nine to 12. A Mines Act in 1923 dealt with the employment of women and children below ground, restricted the hours of adult labour to 60 above ground and 54 below, and enacted a weekly day of rest. The first Workmen's Compensation Act came into force in 1924, and measures were undertaken for the regulation of trade unions and the settlement of industrial disputes. Many of these steps were taken in ratification of the conventions adopted by the International Labour Conference held at Washington in 1919. They were described by the Director of the Geneva Labour Office as " the first tangible results in the East of the ideals inspiring Part XIII. of the Treaty of Peace." The same official formally thanked the Govt. of India for " the conspicuous example of social and labour progress which it is showing to the world." Besides these legislative measures, a quieter process was at work in the steady improvement of the depressing housing conditions in the large labour centres, such as Calcutta, Bombay and Cawnpore. The city improvement schemes there and elsewhere have produced remarkable results, which, even from a purely material point of view, should prove remunerative; for nothing has prejudiced the efficiency of Indian labour more than the periodical flights of the labourer back to the healthier conditions of his native village.

In the social organisation of India the post-War record is one of considerable change. The non-Brahmans of Madras struck against Brahman domination, and seized power in the new provincial legislature. The lowest strata of outcasts or " untouchables " have shown signs of organising for their own protection and betterment, and Mr. Gandhi led a vigorous, if not a wholly popular mission for their uplift. Some flutterings of a feminist movement were perceptible. An accomplished Indian lady, the poetess, Mrs. Sarojini Naidu, occupied the chair of the National Congress of 1925. Numerous ladies of the classes which formerly prided themselves on their seclusion are now to be met on political and other platforms, and some little progress is being made towards the recognition of the re-marriage of Hindu widows. Social progress, however, lags far behind political aspirations.

Recrudescence of Political Crime.—Allusion has already been made to the inroads on the tranquillity of the country which ensued on extremist agitation. They unfortunately provided cover for a revival in Bengal of revolutionary crime on the familiar lines:—dacoities, looting, assassination and the intimidation of witnesses. Conspiracies multiplied in 1923; and early in 1924 an inoffensive Englishman was shot in the streets of Calcutta in mistake for a police official; the Bengal Provincial Conference in the following July passing a resolution laudatory of the " noble self-sacrifice " of the murderer. In Oct. 1924 came a special ordinance for dealing, by exceptional procedure of arrest and trial, with anarchical offences in the province; and among the earliest suspects against whom it was enforced were two members of the Bengal Legislative Council, and the chief executive officer of the Calcutta Municipal Corporation. By the extremists some capital was made of this departure from the ordinary and not too effective methods of the criminal law; but the restoration of order which followed the ordinance was its justification.

The Indian Civil Service.—Not least among the anxieties of the time was the effect of political change on the public services which constitute the main structure of Indian administration. It was not only that members of the Indian Civil and other services found their position substantially altering, as they became transformed from the originators of policy into the subordinate executants of a quasi-parliamentary system. This was inevitable, but it was accompanied by virulent attacks from Indian politicians, who impugned the good faith of the services and made no secret of their desire to replace Englishmen by their own countrymen; and it was accentuated by the domestic anxiety w resulted from the growing cost of living, of passages to Eng and the like. Many valuable public servants retired prematu and the English universities soon stopped the supply of rec of the type that had previously been available.

In 1923 a royal commission was appointed to inquire int whole problem; it was composed of four Englishmen and Indians with Lord Lee of Fareham as chairman. In May it presented a report[1] remarkable for its unanimity. It re mended a large increasein the recruitment of Indians fo services, and the entrusting entirely to local Governmen recruitment for the " transferred " services. On the other h it advised several alleviations of the financial position of E peans in the services, the adequate protection of the servic the execution of their duties, and the establishment of a P Service Commission on the lines familiar in several of the Do ions. These proposals were attacked in the Assembly, but Govt. of India showed their intention of accepting the re and its implications, and certain declarations by the h Govt. made it clear that they were determined to maintain policy of keeping a strong and competent European elen in the leading services. Recruitment almost immediately proved, though certain of the services, particularly civil medical appointments, cannot pretend to offer former attractions to Englishmen.

Indians Abroad.—The Indian Relief Act of 1914 in the U of South Africa and the outbreak of the War in the same pushed into the background for a time the indignation fel India about the treatment of its nationals in certain of the do ions and crown colonies. But the grievance soon acquired incre impetus with the argument that Indian troops were considered enough to fight by the side of forces from parts of the Em which refused civic rights to Indians in peace time. Raised definite form at the Imperial Conferences of 1917 and 1918, issue led to a " reciprocity agreement." Trouble revived, h ever, in various forms in Natal and the Transvaal, in East rica and in Fiji; and the Imperial Conference of 1921 was a called into consultation. It passed a resolution to the effect British Indians domiciled in another part of the Empire sh be given recognition of their right to citizenship. South Af however, where it is estimated that 160,000 Indians are sett declined to be a party to this declaration, and has unifor urged its own responsibility for regulating the status of its habitants in its own interests. In Natal (where the most of Indians are domiciled) and the Transvaal the tendency, in s of theoretical concessions, has been to discourage Indian sett by imposing definite civic disabilities; and the Union Gov support of the " Class Areas bill " has alarmed the Indian tlers, who believe that it will be used as a weapon for the pulsory segregation of Asiatics in urban areas.

Bitter though the feeling became in South Africa, it reac an even more acute point in Kenya, where at one time th seemed an imminent prospect of open hostilities between British and the Indian settlers. There the Indians had grievances: the closure of the highlands of the colony to th compulsory segregation, inadequacy of their franchise and re sentation and threats to stop immigration. From an inq held by the Colonial Office in 1923, a policy was announced H.M. Govt. which, though conciliatory on most of the point issue, failed to allay the sympathetic agitation in India; and whole question was again brought before the Imperial Con ence in the same year. Four of the Dominions and the Colo Office itself accepted the principle of consultation with Govt. of India on the status of Indians in the Dominions Colonies; South Africa stood alone in refusing to hold any hopes of the extension of the political rights of the Ind residents. From the informal discussions that ensued, a m accommodating temper developed. In Kenya the former set ment was modified by the Labour Govt. in 1924, and tens was relaxed by the local Indians accepting certain nominati for the legislature. In South Africa the patient labours of a de

from India paved the way for the appointment of a con-
e to which the Union Govt. assented in April 1926.

those who do not know India, there is difficulty in appre-
g how seriously these grievances react on the political situa-
here. They are universally interpreted as betokening racial
ance, an intention to humiliate Indians as such, and the
ion in practice of that Imperial citizenship which India is
offered in theory. They provide extremists with a handle
timulating popular indignation against the British Govt.
hey complicate its task. On the other hand, little allowance
en made in India for the considerations which are of vital
ent to a European community imbedded in a vastly larger
enous population.

e North-West Frontier.—On the conclusion of the War which
ew Amir forced on India in 1919, there came clear evidence
revival of Russia's old thrust towards India. It was with a
to fomenting revolutionary trouble in India that Bolshevik
icles were pushed into Persia and Afghanistan; and when in
a Russo-Afghan treaty was concluded, one of its chief fea-
s was the establishment of Russian consulates so near the
n border as Kandahar and Jālālābad. The Amir was not
se from playing off one of his neighbours against the other;
after inviting a mission from India to come to Kabul and
tiate an Anglo-Afghan treaty, he kept it dangling through-
1921 before coming to final terms in Nov. of that year.
conditions included the complete independence of Afghan-
, and the opening of legations at London and Kabul. With
ccrediting of an Afghan Minister to the Court of St. James,
riod of greater cordiality was inaugurated, though serious
ion arose in 1923 over the Afghan attitude towards certain
tier outrages, and in 1925 a Russo-Afghan Trade Conven-
indicated the continued flirtation of the Amir with his Soviet
hbours. He has also secured a treaty of alliance and mutual
nce with the new Turkish Govt. of Angora. Meanwhile he
embarked on a programme of domestic reform and progress,
h offers some promise of opening his country to European
ences.

elations with the frontier tribes improved after the cam-
ns of 1919 and 1920; but in 1923 a gang of outlaws in Afghan
itory were guilty of slaying two British officers near Landi
al, of shooting the wife and abducting the daughter (after-
ds gallantly rescued) of an officer in Kohat cantonment, and
nurdering another officer and his wife at Parachinar. Apart
n the necessary punitive measures, the Govt. of India initi-
l a permanent policy of controlling the Mahsud country, one
he chief storm-centres on the border. Dropping the plan of
tary occupation, they adopted a scheme of penetration of
ls suitable for motor transport, guarded by local irregulars,
commanded by two strong posts at Razmak and Manzai.
even higher importance was the extension by five years of
our in the most forbidding country, of the Khyber railway
n Jamrud to Landi Khana; the first train through the Khyber
ss being run on Nov. 2 1925. A new treaty was signed with
pal in Dec. 1923. It contains provisions for mutual informa-
n of any trouble with adjoining states, and others for regulat-
the transport of arms and merchandise. The traditions of
ndship with this allied state have been strengthened.

Retirement of Lord Reading.—At the end of March 1926 Lord
ading laid down the office which he had filled with courage
l distinction during a period of special difficulty. By the exer-
of extreme patience, he had allowed the vehemence of 1921 to
aust itself without deriving fresh food from any untoward
p of the Government and he had guided the inevitable reaction
o constitutional channels. He had taken measures for the
ncial health of India, and particularly for economy in its
litary administration. He had been diligent in removing
evances within India and vigilant for her interests abroad.
retirement he received the high honour of promotion to Mar-
ess: and he was succeeded by Lord Irwin of Kirby Moordale, a
ndson of the Sir Charles Wood who, as Secretary of State for
lia, had laid down the lines of the existing educational system
1854.

II. EDUCATION

The dominant factor of the educational system continues to be, as from the East India Company's days, the insistent demand of the middle-classes for secondary and university education as a means of livelihood. This has been supplied by the State to the limits of its means on very cheap terms, to the comparative neglect of the agricultural and labouring classes who, while not actively hostile to the schoolmaster, were well content to do without him. The effects of this neglect, the failure of secondary education to meet the needs of the country's industrial development and the largely unsatisfactory character of such education for any purpose combined to make educational reform the most urgent, as well as one of the thorniest, of current administrative problems. The lines laid down by Lord Hardinge's Govt. were vigorously pursued by his successors.

University Education.—The Calcutta University Commission reported in 1919. Presided over by Sir Michael Sadler, it consisted of seven members, of whom four came direct from England and two were Indians. The report condemned in emphatic and impressive language the whole system of secondary and university education, as it existed in Bengal, and, subject to qualifications, in other parts of India. It was based on an external examining university and a multitude of affiliated colleges scattered throughout the country. It was content to leave the ordinary student to believe that the passing of examinations is the only thing of value in a university training. The affiliated colleges were, as a rule, poorly staffed and equipped; the teaching mechanical; and the conditions for the students pitiable. The secondary schools feeding the colleges were even worse; and boys entered the university so ill-prepared that the first two years were spent in what was really school and not college work.

The commission advised radical reforms. The universities should be centralised, unitary, residential, teaching bodies with a government of their own. Tuition of a preparatory and not a university type should be removed to a new grade of intermediate colleges, where the curriculum would be of a varied kind and would lead up to appropriate examinations not under university control though qualifying for entrance to a university, and having an independent value as a certificate of general education. Students would thus enter the universities at a later age and at a stage represented by the old "intermediate" examination, thus relieving the universities of a part of their unwieldy host of undergraduates. These recommendations were generally welcomed, and most of the former universities (including the Hindu University at Benares, which owed much to the energy of Mrs. Besant) have been re-constituting themselves accordingly, while new universities of the teaching and residential type are being built up at Dacca, Aligarh (Moslem), Lucknow, Rangoon, Patna, Nagpur and Delhi; yet another being under contemplation at Agra to relieve the external work at Allahabad. The multiplying of universities, however, may go too far; there is already some danger of the lowering of standards, in competition for undergraduates; and it is hoped that an Inter-University Board for all India will be strong enough to maintain standards and insist on modern methods of instruction. The latest returns were materially affected by the boycott of governmental institutions under Mr. Gandhi's stimulus; but they showed the number of students at universities and colleges to be in the neighbourhood of 60,000, of whom more than two-thirds were Hindus, and not so many as 3% women.

Secondary Education.—The establishment of "intermediate" institutions advised in the Sadler report, and the equally essential improvement of the mass of high schools, have not progressed so rapidly as university reform, mainly owing to the shortage of funds. Boards for secondary and intermediate education, however, have been set up in several provinces and improvements are being slowly effected. The attendance at secondary schools of a non-technical type in 1922 was 1,240,000, females being in the ratio of rather over 10%. The "national" schools, with their cult of the spinning-wheel, which Mr. Gandhi started at the height of his non-co-operation movement, have now largely disappeared, the best of them having been rescued by applying for official recognition. Technical and commercial schools were equally handicapped by narrow means, and the 1922 attendance at them was only some 21,000.

Primary Education.—The pace of development here has recently been seriously retarded by financial difficulties; in 1909 the number of children at primary schools was 4,420,000; in 1918 it was 6,000,000; by 1922 it had risen only to 6,310,000. And yet it is from them that all true improvement must start, as well as all hope of creating an intelligent electorate. The difficulties are many: the traditions which confine education to certain castes, communal troubles, bad communications, the dearth of competent teachers, but above all the poverty of the rural parent, who cannot spare his sons from the ranks of the bread-winners and has no belief whatever in educating his daughters. To these permanent obstacles must be attributed the fact that, according to the census of 1921, only 122 in every thousand men, and 18 in every thousand women, in the country can read and write. Scarcely 3% of the population are enrolled in the primary schools, and the total numbers under instruction of all sorts are 9,300,000 out of the 247,000,000 inhabitants of British India. In face of these figures it is not surprising that the legislatures have frequently turned to the remedy of compulsion. Acts asserting the compulsion principle have been passed in several provinces, but the translation of principle into practice is still incomplete. Meanwhile the decentralisation of primary education offers a prospect of greater elasticity, especially in adapting the school curriculum to rural needs.

III. DEFENCE

Indian Frontiers.—The defence of India is a three-fold problem—the protection of its land frontiers, the maintenance of internal order and the guarding of its seaboard. It is natural to think of the frontier problem mainly in terms of the turbulent northwest border, where the military strength has so long been obliged to concentrate. Not only is the attitude of the tribes incalculable, but Afghanistan, though the present treaty relations with it are excellent, has too often developed a spirit of unprovoked aggression in the past; and the ancient menace of a Russian invasion through Afghan territory has, after long abeyance, revived in the new form of Bolshevik activity directed against the stability of government generally and British government in particular. "The road to London," declared Lenin in 1920, "is through Kabul and India."

But grave though these preoccupations are, other frontiers must not be forgotten. On the northeast, Nepal is a state of considerable military importance which furnishes, from its Gurkha peasantry, some of the best material in the Indian army. Fortunately it has a long tradition of friendship with India and many common interests. Behind it however and marching with India on its flanks lies Tibet, harmless enough in normal times, but always liable to Chinese influence. China herself adjoins Burma for over 1,000 m., and occasional lawlessness affords some indication of what might follow the development of an unfriendly spirit at Peking or even in the province of Yunnan. Further south, a fringe of French Indo-China and then 600 m. of Siam complete the Indian border.

Nevertheless, the northwest frontier remains at present the focus of interest. Its military risks are enhanced by the extraordinary physical difficulties of the country, by the almost unparalleled fierceness of its climate, by the fact that the sturdy mountaineers are now well-armed, and also by the oscillation of the British Govt. in the past between a policy of standing on an artificial borderline against the Pathan tribes and a forward policy of advancing the British sphere of influence, or even of control, towards the frontier of Afghanistan proper.

The Kitchener Reorganisation.—It was thus on the defence of the northwest frontier that Lord Kitchener riveted his attention when, in the course of his long tenure of the post of commander-in-chief, he set himself to the task of reconstituting the army in India. Though able men before him had done much to make it an efficient instrument of war, Lord Kitchener brought to bear upon the problem new ideas and methods. The organisa
the Indian Army which he inherited dated from the M
It failed, he considered, to distinguish sufficiently between
quirements of internal security and those of offensive w
It did not earmark troops for these two distinct purpos
train and equip them accordingly, but left the selectio
mobilisation of an active army in the event of war to t
moment. Lord Kitchener aimed, therefore, at creating
the forces at his disposal (some 230,000 men in all), a fiel
capable of being immediately mobilised, of the strength
he considered would be required to defend India against
sian advance through Afghanistan, until help could be ob
from England. He proposed to mark off this army fro
troops allotted for internal defence, to distribute it conven
by divisions (each division comprising some 13,500 comba
of all arms), in homogeneous military areas, and to train
war formations under the generals who would command
field. He broke up the four army commands which he
existing, and replaced them by nine divisional command
each divisional command he proposed to place a self-cont
division of the field army, together with the necessary co
ment of garrison troops that would be left behind for in
defence in the event of mobilisation. When fully mobilise
field army would comprise some 120,000 combatant troop
more than half the total strength of the army in India. Ade
transport and supplies were to be provided and every arr
ment made to enable each division of the field army, thoro
trained and fully equipped, to pass rapidly to a state of war,
required, without confusion and dislocation.

It was a large scheme, involving many subsidiary ref
such as enlarged staffs, extensive re-grouping of troops and
ing of barracks, better training and equipment, increase
and allowances for the soldier. It had only been partially
into execution when the War broke out; financial difficultie
intervened, and the fear of Russian aggression had been al
by the Anglo-Russian agreement of 1907. In the meantime
greater progress had been made in the United Kingdom i
organisation, training and equipment of the British Army,
expeditionary forces dispatched from India were found in
earlier stages of the War to be inferior in these respects t
British troops. Then came the serious complaints of the effici
of the higher military command in the Mesopotamian campa
leading to the inquiry set up by Act of Parliament, and
grave indictment of the Indian military system as regards
administration and organisation, contained in the report of
George Hamilton's Commission (Cmd. 8610 of 1917). The
tem was described as cumbrous, slow-moving and over-central
in the last degree. Almost immediately ensued the Afghan
of 1919, followed by the Waziristan campaign, with rene
complaints against Indian army administration.

The Esher Committee Report.—It was thus decided to set
a Committee, with Lord Esher as chairman, to inquire into
organisation and administration of the army in India. In
judgment of this committee, which reported in 1920, the exist
military system was defective in many respects. Their reco
mendations involved considerable modifications of the Kitche
scheme. To one of them prompt effect was given; the nine
sional commands created by Lord Kitchener were replaced
smaller territorial units, and these were grouped into four ar
commands, the commanders of which would take over much
the responsibility which had hitherto been centralised in
commander-in-chief and army headquarters. The more i
portant proposals of the committee regarding the functions
the military forces in India in any scheme of Empire defen
the authority to be exercised over them by the British W
Office, and the position and duties of the commander-in-ch
were hotly contested by the Indian Nationalists, who saw
them a design of subordinating the Indian Army to the neces
ties of the Empire and of encroaching on the independence
India.

Indian Army.—The army in India is composed of Briti
regular troops, which form part of the British Army transferr

period of service to the Indian establishment, and of the n Army. The latter consists of Indian troops raised by ndian Govt. and commanded by Indian officers holding Viceroy's commission and by British officers holding the 's commission. The numerical proportion in which the component parts of the army should stand to each other ixed in the first instance in 1858, and further considered 393, when the ratio of one British soldier to 2·5 Indian ers was definitely adopted and has since been adhered to as permanent basis. The proportion is struck on the regular s, including the imperial service troops maintained by Indian s. No account is taken, on the one hand, of the Auxili- Force, recruited from the European and Anglo-Indian nunity, or, on the other hand, of the reserves of the Indian , the Indian territorial force, the armed police, or the s of the Indian states.

e British troops are necessarily the most costly part of the nisation; both on this account and from a sense of national , Indian critics of military expenditure constantly press reduction in the British element. In the course of a de- in the Central Assembly in March 1921, the then commander- ief, Lord Rawlinson, stated the case for not altering the ortion of British to Indian soldiers while the existing irements of internal and external defence remained. Other ures of great importance however have been taken to meet aspirations of Indian Nationalism for an Indian share in country's defence. Since the War, King's commissions been made available for Indian gentlemen who qualify as ts at the Royal Military College, Sandhurst, where 10 ncies are reserved for them annually. In order to secure ble candidates for Sandhurst, a military college has been lished at Dehra Dun, with a six-years' course of preparatory ation. The question of providing a Sandhurst training ly in India was subsequently referred to a special committee, hich two of the Nationalist leaders consented to serve.

r the effective employment of young Indian officers hold- he King's commission, it has been arranged to officer eight of the Indian Army entirely by Indians, gradually as their and length of service may justify, with the object of thus ituting the nucleus of a national Indian Army in the future. her momentous step was the enrolment of an Indian terri- l force in 1921. It consists of 20 provincial battalions, t 12,000 strong, liable for general military service; and are in addition a number of university training corps. gside of these the old volunteer force continues under her name. It is now the Auxiliary Force, confined to pean British subjects, and liable only for local service in gencies.

1914 when the War broke out, the regular forces in India prised 75,575 British soldiers, including 2,689 commissioned ers; 159,861 Indian Army troops, including 2,771 Brit- commissioned officers and 341 British warrant and non- missioned officers; and 21,069 imperial service troops. The ves of the Indian Army numbered 36,000 odd, and the nteer force consisted of some 38,000 Europeans and Anglo- ans. During the War the Indian Army was greatly enlarged, emands were made upon it by the home Government for ice abroad. In the last year of the War the Govt. of a undertook to raise an additional 500,000 combatant uits, and no doubt the full number would have been secured the Armistice not intervened. Demobilisation began in 1919, but was interrupted by the Afghan War and the equent campaign against the tribes in Waziristan. On Jan. 926 the Indian troops serving in the country mustered 668 men, or approximately the pre-War strength; the ish troops were only 60,359 men, or some 20,000 below pre- strength. The defence charges in India before the War were it £20,000,000 a year; after all the economies advised by Inchcape Committee, they are in the neighbourhood of 500,000, which represents an annual charge, for the pro- ion of their country, of 3s. per head of the population of ish India.

Naval Defence.—The third branch of India's defence, the protection of her vast seaboard, has hitherto been left to the British Navy, with minor assistance from the Royal Indian Marine. Without that powerful aid, India's weakness would be disastrous. "Her sea-borne trade," writes Professor Rushbrook Williams, "is rich; the proportion of her wealth collected into centres within practicable distance of her coastline very great. Good harbours are few; and from the naval point of view, with certain exceptions, not easily defensible. It seems, therefore, no exaggeration to state that adequate naval protection will in future constitute a postulate of her national existence. Should her surrounding seas fall under the dominance of her foes, she can never be secure along the road to prosperity." At present India makes an annual payment of £100,000 towards the navy, and maintains the Royal Indian Marine. Nationalist sentiment has combined with a recognition of India's helplessness at sea to claim the institution of an Indian Navy and the creation of a class of Indian naval officers; there is also a demand for an Indian mercantile marine assisted by the State. In the spring of 1926 the Government announced its intention of setting up a Royal Indian Navy, at a cost of 63 lakhs (£420,000) a year. With its headquarters at Bombay, it will be composed at first of 4 sloops, 2 patrol craft vessels, 4 trawlers, 2 service ships and 1 depot ship. It is to be a sea-going force, whose function in peace time will be the training of personnel for war service in the Indian Ocean and Persian Gulf, port defence, survey work and marine transport. (ME.)

IV. THE INDIAN STATES

The relations now subsisting between the Indian states and the British Govt. are the outcome of an evolutionary process which still continues (*see* 14.407 *seq.*). The Mutiny, the passing of the East India Co. and the grant of *sanads* of adoption to the rulers in 1862 obliterated the peril of annexation, breached the barriers of isolation and inaugurated for the states a new era of union under the Crown. Queen Victoria's proclamation of 1858 announced to the "Native Princes of India" that all treaties and engagements made with them would be scrupulously observed and that their rights, dignity and honour would be respected. The British Govt., while emerging as paramount power, thus guaranteed to the ruling princes and chiefs the measure of sovereignty which they severally possess in their internal affairs. As regards the nature and extent of this sovereignty, the following extract from a minute by Sir Henry Maine may be quoted: "There may be found in India every shade and variety of sovereignty, but there is only one independent sovereign, the British Government. . . . The mode or degree in which sovereignty is distributed between the British Govt. and any Native State is always a question of fact which has to be separately decided in each case, and to which no general rules apply." Two important principles have, however, been laid down by statute, namely, first, that the Indian states "have no connections, engagements or communications with foreign powers," and second, that the British Govt. has the right to protect and govern subjects of the states when resident or found abroad. For international purposes, therefore, state territory is in the same position as British territory, and state subjects as British subjects.

Status of the Princes.—The assumption of the Govt. by the Crown in 1858 called the princes to greater responsibilities as well as to higher honours. Lord Curzon speaking at Gwalior in 1899 claimed the rulers of the states as his colleagues and partners in the administration of the country. Their new prerogatives involved obligations not envisaged when the treaties were framed, but proceeding naturally from the solidarity of the states with British India. Many forces were at work tending to draw the relationships between the princes and the Crown into conformity with a single type, and also to increase the Govt. of India's interest in the administration of the states. The result was over-rigidity of treatment and the formulation of rules which seemed to the princes to transcend the provisions of treaties. Lord Minto, perceiving an atmosphere of discontent, took the occasion to make a declaration of policy, during a visit to the Maharaja of Udaipur in Nov. 1909. He interpreted the proclamations of Queen Victoria and King Edward as inculcating a more sympathetic, and therefore a more elastic policy, and he laid stress on the fact that the foundation stone of the whole system must be the recognition of identity of interests between the Imperial Govt. and Durbars and the minimum of interference with the latter in their own affairs. Lord Minto had already taken the princes into his confidence by consulting them officially on the question of the growth of sedition in India. His declaration and the spirit in which it was acted upon gave great satisfaction to the ruling princes.

Lord Hardinge, pursuing the same policy, in 1913 and 1914 invited some of the princes to meet him in conference at Delhi to discuss a scheme for founding a central college at Delhi at which students from the various chiefs' colleges might complete their education and take a degree. H.H. the Maharaja of Bīkaner delivered a notable speech at the 1914 gathering when, speaking on behalf of his brother princes, he said:—

> We trust, and we are confident that Your Excellency will before long convene similar meetings to deal with other subjects in which we and the states represented are no less closely concerned than this one of the college, and on which our deliberations will not only be of the greatest advantage to ourselves, our states and our people, but also, we hope, of some value to the Imperial Government.

Lord Hardinge in 1914 created a new post of political secretary to the Govt. of India, in order that closer attention might be devoted to relations with the states. The past fifteen years had proved an era of striking progress and development, and the rulers themselves, encouraged to play more important parts in the drama of Indian affairs, were becoming daily more advanced in their own administration, so that new methods of political treatment were required.

In Aug. 1914, on the outbreak of the War, the princes vied with each other in the offer of loyal service. In a telegram which stirred England the Viceroy reported that the rulers of the states in India, numbering nearly 700, had with one accord rallied to the defence of the Empire and offered their personal services and the resources of their states. From among the many princes who had volunteered for active service Lord Hardinge selected seven rulers, including the veteran Sir Pertab Singh (Regent of Jodhpur), who would not be denied his right to serve the King Emperor in spite of his 70 years. His nephew, the Maharaja, who was but 16 years old, went with him. Contingents of all arms were accepted from 12 states, besides a camel corps from Bīkaner. A hospital ship was given by various states at the instance of the Maharaja of Gwalior, and as the War progressed there were many fresh evidences of the spirit of loyalty animating the princes and their peoples. The support afforded by the Durbars in the matter of raising recruits was of particular value.

Minorities and Successions.—In 1916 Lord Chelmsford, in spite of War preoccupations, decided to invite the princes to another conference. In his opening speech he laid stress on the magnificent assistance rendered by the states. The most important of the subjects discussed at the conference related to the form of administration to be adopted in a state during a minority. In 1909 Lord Minto had become aware that several of the rulers felt strongly that they had a right to be made acquainted with the considerations which guided Government in minority administrations. He therefore ascertained the opinion of the leading Durbars, and prepared a statement of the general policy of Government in the matter. In 1915 attention was again drawn to the matter in consequence of representations made by certain of the rulers that in some cases in the past the rights and privileges of states guaranteed by treaty or otherwise had been unwittingly infringed during the minority period by the exercise of the prerogative of the paramount power.

Lord Hardinge thereupon convened a committee consisting of three rulers of states and three political officers to consider the question. Their recommendations were fully debated in the conference of 1916, with the result that a resolution was published in Aug. 1917 laying down the principles for th duct of minority administrations. In it the Govt. of asserted their rôle as trustees and custodians of the interests and traditions of a state during a minority admitted that the special conditions of each state re special treatment, and promised to attach due weight to re by individual ruling princes or chiefs regarding any prin which they might wish to be adopted in the case of thei states or families, while reserving to themselves freed action in dealing with such requests. Seventeen general ciples were laid down for observance during minority ad trations. The resolution was received with much satisfa by the princes, and the general opinion was that the prono ment of Government was an event hardly second in con tional importance to the *sanads* of adoption granted by Canning.

The next conference, held in 1917, saw the decision of an very important question, viz.: the form of recognition by ernment of successions in the states. Lord Chelmsfor nounced that in the case of the succession of a direct natura recognition on the part of a paramount power was purely fo and that the obligation on the part of the new ruler to o it in no way impaired his inherent right to succeed. He als nounced the relaxation of the requirement that rulers of s before paying visits to places in British India should obtai previous concurrence of the local Government concerned. requirement had proved irksome in practice, and under the arrangement the obligation was limited merely to visits t stations and other places where special local conditions render concurrence of the local authorities necessary.

The Chamber of Princes.—His Highness the Mahara Bīkaner, who earlier in the year had been one of the I representatives at the Imperial Conference and a member o Imperial War Cabinet, took the lead in this conference. I final address to the Viceroy he expressed the hope of the pr that before the British Govt. came to any decision on the ject of political reforms to be introduced in British India ruling princes would also be consulted. He stated:—

> We feel that we too must keep a definite goal in front of us, whilst it is essential that our rights and privileges and our pos as allies and friends guaranteed to us by solemn treaties and en ments with the British Govt. remain unaltered, our states ca afford to lag behind in the general advance which India's ass tion with Great Britain alone has rendered possible. It is for t reasons that we are now all the more anxious to see the early es lishment of a constitutional chamber which may safeguard interests and rights of ourselves and of our states.

Lord Chelmsford replied that any scheme which they m put forward would receive most careful and sympathetic sideration from the Govt. of India. A draft scheme was acc ingly prepared by a committee, and was discussed informally the Viceroy and certain of the princes in the presence of Montagu in Feb. 1918 during his visit to India. In Dec. the King issued a royal proclamation signifying his assen the establishment of a chamber of princes, which was e tually inaugurated by the Duke of Connaught in Feb. From the proclamation then read, we quote the following:—

> In my former proclamation I repeated the assurance, give many occasions by my Royal predecessors and myself, of my d mination ever to maintain unimpaired the privileges, rights dignities of the princes of India. The princes may rest assured this pledge remains inviolate and inviolable. I now authorise Viceroy to publish the terms of the constitution of the new cham My Viceroy will take its counsel freely in matters relating to territories of the Indian States generally, and in matters that a those territories jointly with British India, or with the rest of Empire. It will have no concern with the internal affairs of ind ual states or their rulers or with the relations of individual state my Government, while the existing rights of the states and t freedom of action will be in no way prejudiced or impaired.

His Royal Highness also conveyed to the princes a spe message of thanks from His Majesty in public acknowledgm of their splendid record of achievement during the War. alluded to the fact that H.H. of Bīkaner had taken part in Peace Conference and had signed the Treaty of Versailles, wh

. the Maharaja of Nawanagar had attended the League of
ons Assembly at Geneva. H.H. the Maharaja of Bīkaner
appointed to be the first chancellor of the chamber (Naren-
Mandal), and was re-elected to the office each year until 1926
he was succeeded by H.H. the Maharaja of Patiala.

ith the growth of new conditions and the unification of
a under the British power, a body of usage affecting the
y position of the states had insensibly come into being, and
Durbars were therefore anxious that for the future they
at have a voice in the formulation of political practice.
mmittee of princes, known first as the codification com-
ee and afterwards constituted as the standing committee
he chamber, accordingly met at regular intervals and
eved useful work with the advice and assistance of officers
the secretariat and administrative departments of the
t. of India in revising the summaries of political practice
r various heads such as mining concessions, railways, tele-
hs and telephones, mints and currency, opium, extradi-
, etc. The results were reported at successive meetings of
chamber of princes.

he Salute states in the Punjab Province were taken into
ct relations with the Government of India in Nov. 1921,
ugh the appointment of an agent to the Governor-General.
milar arrangement was made in 1923 for the five states in
Madras Presidency, and in 1924 for the Bombay states of
hiāwār, together with Cutch and Palanpur. A new first-
s political appointment was created for the last-mentioned
p, and the Bombay Political Dept. was amalgamated with
of the Govt. of India. In 1921 the Gwalior state was
rated from the Central India Agency and was brought
direct contact with the central Government through a single
rmediary officer, while in Rājputāna the states of Bīkaner,
hi and Jhālawār were at different times placed in direct
tions with the agent to the governor-general instead of
ugh a subordinate political agent. At the meeting of the
mber in the autumn of 1921, Lord Reading announced that
the future, except at installations and investitures, where
l custom would continue to be followed, the King had been
sed to dispense with the presentation of nazars at ceremonial
ts or receptions, either to himself or to the members of his
ily or to any of his officers to whom it had hitherto been
omary to present them.

n 1918 and 1921 the King conferred many honours and
inctions upon ruling princes and chiefs and others in
gnition of the services rendered by the Indian states during
War. The style of " His Exalted Highness " was conferred
n the Nizam of Hyderābād, and the title of " Faithful Ally of
British Govt." was formally confirmed to him. The Prince
Vales, during his Indian tour, in the winter of 1921–2, visited
ny of the states and was received with loyal enthusiasm and
ndid hospitality. At the Imperial Conferences of 1921 and
3 respectively T.H. the Maharao of Cutch and the Maharaja
Alwar were included among the representatives of India, and
the meetings of the League of Nations from 1921 onwards
I. the Maharao of Cutch, the Maharaja of Navānagar (twice),
Maharaja of Bīkaner and the Maharaja of Patiāla.

Soon after the War, certain problems in connection with the
anisation, training and maintenance of the Imperial service
ops were taken up by the Govt. of India in consultation with
ruling princes and chiefs concerned. His Highness the
haraja of Alwar, after pointing out that the greater states
l, during the War, not only placed their units of Imperial
vice troops at the disposal of Government but had depleted their
n power to keep these units up to full strength, advocated a
nplete policy of trust in the states and asked that the policy
ght be applied in such a manner as to eliminate all distinctions
ween Imperial service units and the local forces or armed
ice of the states. After prolonged consideration, a compre-
nsive scheme was prepared for the reorganisation of the
te forces, embracing not only the first line troops but also the
egular troops and the state police. The armament and equip-
nt of the first line troops was to be improved, the irregular troops were to be armed and organised in such a way as to transform them into an efficient reserve, while the police were to be given suitable weapons to enable them to cope with dacoits. More than thirty states joined in the scheme. To facilitate the training of military officers, certain vacancies at the Prince of Wales' military school at Dehra Dūn were offered to boys nominated from Indian states.

In view of the contemplated repeal of the Press laws of British India, a resolution passed in the chamber of princes in 1921 asking that some special means of protection might be given to the Indian states in place of the relevant provisions of the Press Act. Lord Reading's Govt. considered that they were obliged in honour to agree to such protection, but the Legislative Assembly vigorously opposed a bill which was brought in under the title of Indian states (Protection against Disaffection) bill. It became necessary for the governor-general to exercise the extraordinary powers allotted to him by the Govt. of India Act, and to certify that the bill was essential for the interests of British India. The bill was passed by the council of state and eventually became law.

In 1908 the Govt. of India recommended to the Secretary of State that the necessary legislation should be undertaken in order to enable subjects of Indian states, while retaining their primary allegiance to their states of origin, to become eligible for certain services in India, admission to which was under the existing law confined to British subjects. The required provision was eventually made in Section 96A of the Govt. of India Act.

A New Indian State.—Before Lord Minto left India, he announced at Benares that the Govt. of India, with the sanction of the Secretary of State, had decided to grant to the Maharaja of Benares and his successors a permanent status amongst the rulers of India, by constituting part of the family domains as a state. This remarkable step, which involved the transfer of some 300,000 persons from British to Indian rule, was taken in view of the unique position of the Benares House, representatives of which had played important parts in relation, first to the court of Delhi, and afterwards to the British Government. The change was effected by means of an instrument of transfer, the provisions of which ensured to the residents of the territories the rights and privileges which they had enjoyed under the British administration. In 1919, in view of the success of the measure, the town of Rāmnagar, adjacent to Benares City, was also handed over to the Maharaja for use as his capital. In 1913 the instrument of transfer in virtue of which the province of Mysore had been transferred in 1881 to the present ruling family of the Mysore state was superseded by a treaty, the wording being altered in certain respects to meet the wishes of the present ruler. The change was announced during Lord Hardinge's visit to the state in the same year.

Constitutional Development.—While the paramount power has parted with none of its prerogatives, the evolutionary process has gradually led to a certain breaking down of the isolation of the states among themselves, the strengthening of their position and the advancement of the dignity of the princes. They not only gained, in the chamber, means for expression of their collective needs and opportunity for influencing the development of political doctrine, but they were admitted, as joint representatives of India, to the innermost councils of the Empire through the appointment of a member of their order to successive Imperial Conferences and meetings of the League of Nations.

Thus the integral connection of the states with the British Empire has been further emphasised, and the possibility that constitutional changes in British India may react on the states has been more effectively recognised. In a few advanced states, legislative bodies have been constituted analogous to those in British India, Mysore being a prominent example, while in others the rulers have devised means for the people to voice their grievances and aspirations more easily through consultative councils. The movement is unhurried, as the time and manner of change, if change there is to be, rests with each individual ruler. But it cannot be denied that the processes at work in British

India must impair the vitality of the conservative traditions which have their stronghold in the states, and for this reason, the princes must be keenly interested in the development of constitutional reforms beyond their borders. While it is an accepted axiom that the independence of the states in matters of internal administration carries with it the counter-obligation of non-interference in British Indian domestic affairs, any fundamental change in the system of government in British India may be claimed to fall within the category of matters of Imperial or common concern, in regard to which the princes may reasonably expect to be heard. (R. Hd.)

V. ECONOMIC HISTORY

General Survey.—The economic history of India during the seventeen years 1909–25 falls naturally into three chronological divisions: pre-War, War and post-War.

The first period was one of rapid progress. After the famine year of 1908 the monsoons were satisfactory, and the harvests good. The general conditions of world trade favoured Indian commerce and Indian prosperity. Exchange was steady, budgets showed surpluses. As a debtor country India profited by the general rise of prices, needing to export smaller quantities of goods to meet interest charges. As also the prices of foodstuffs and raw materials were rising faster than those of manufactured goods, the exchange of Indian exports for imports was carried on with greater profit to India. In these five years the money values of Indian sea-borne trade increased by 40%; the gross earnings of the railways and of the post office by one-third. Characteristically, the increased purchasing power was used to absorb gold and silver to the amount of £127,000,000. But also some notable new industrial enterprises were launched, and a stronger spirit of enterprise was displayed both in commerce and industry.

The outbreak of the World War produced a temporary panic, quickly allayed. The interruption of foreign trade threw India largely upon her own resources. Efforts were made for the production of manufactured articles, particularly War requisites, not previously attempted, and various industries which work up native raw materials for the home market expanded considerably. A strong stimulus was given to the old demand that the State should take a leading part in the development of Indian resources, both by means of a protective tariff, and by helping private enterprise in the raising of capital, by research and by developments of the educational system; and a great change took place in the attitude of the Government to these questions.

The transition from the War period to international peace was marked by the "famine" of 1918, followed by another monsoon failure in 1920; by the visitation of influenza, which in 1918 and 1919 probably killed not fewer than 10,000,000 people, by much political agitation and the recasting of the constitution. A post-War boom of trade in 1919 and 1920 was followed by a severe slump in 1921 and 1922; exchange fluctuated violently, the sterling value of the rupee first rising to a record height, and then falling in a most embarrassing manner. Five years in succession showed budget deficits, amounting in the total to over 100 crores.[1] But in 1922 a steady recovery began, well maintained till the end of 1925. The monsoons, during the five years 1921 to 1925, were on the whole good, and, given good monsoons, Indian commerce is solidly based on an imperative world need for Indian staple products. There was a "return to normalcy," but not to the pre-War normal. The War cataclysm has left among its permanent effects important economic and political changes including a reversal of fiscal policy from free trade to protection.

Agriculture and Irrigation

Since the census of 1921 showed that 70% of the total population of the Dominion were supported by agriculture and pastoral industry, not Indian agriculture only, but all Indian economic prosperity is necessarily a gamble in rain. During the period under review only two serious monsoon failures occurred, those of 1918 and 1920. That of 1918 was one of the worst on r
over all India the estimated out-turn both of rice and of
was in 1918–9 25% below the previous quinquennial av
This was much worse than in the great famine of 1899, but

was partly because the harvest of 1917 had been a recor
so that the famine year was helped by an unusually large
over; but it also indicated that government efforts to pr
agricultural prosperity had achieved a large measure of su
The great shortage in the total amount of grain available i
country necessitated exceptional measures, in addition t
well-tried methods of dealing with unemployment and
tution. Export of grain was prohibited; the surplus of B
was secured by India, and 200,000 tons of wheat were imp
from Australia. The failure of the later rains in 1920 proc
famine conditions in certain districts in the early part of
and the number on relief went up to 400,000; and it wa
till after the country had recovered from that shortage
export of grain could again be freely permitted.

At the biennial meeting in Pusa, in Dec. 1919, of
Board of Agriculture, a conference of Imperial and Provi
Departments of Agriculture, the problem of famine policy
once more re-examined in the light of the experience of
and a new programme was drawn up of measures calculate
minimise the loss of grain, fodder and cattle during yea
deficient rainfall, including plans for improving the storag
grain, the growing of better fodder crops, evolution of impr
varieties of drought-resisting cereals and emergency mean
irrigation. Special attention was given to the great los
cattle, though this had been mitigated in the Bombay Dec
one of the worst areas, by the success of the Bombay
cultural department in turning prickly pear into valuable fo
by burning off the prickles in the flame of the blacksm
forge. Meanwhile among the intelligentsia of the towns t
arose a foolish and short-sighted demand for the prohibitio
export of foodstuffs even in normal years, a demand whic
successful, would multiply and intensify famines by remo
the commercial incentive to agriculturists to produce a surplu

The Departments of Agriculture had been reorganised e
in the twentieth century, and, with still very inadequate
sonnel and funds, they have achieved important results
great variety of directions. One important branch of
work consists of the introduction of improved varieties of pla

famous; very valuable work has also been done on suga
Coimbatore. The work of provincial departments is too va
to be even summarised here; as examples, taking one prov
(Madras) only as representative, mention may be made of
Agricultural College at Coimbatore; the introduction and p
ularisation of Cambodia cotton, which gives upwards of 200
of superior lint per acre, as compared with the ordinary In
crop of 80 lb. of short staple cotton; the vigorous propagand
single paddy transplantation and the growing of green man
which has been of immense value to rice cultivators; the selli
on a large scale at cost price of fish manure; the fight agai
insect pests of cotton and other crops by the Madras Pest A
and its system of popular education in agricultural science
means of simply expressed tracts in the vernaculars.

A forward step was taken along the lines of linking toget
the efforts of all the agricultural departments by the establis

---

[1] Lakh = 100,000 rupees; crore = 10,000,000 rupees.

ent in 1920 of the Indian Cotton Committee, which is financed a small cess on each bale of cotton produced. This has been llowed by measures for the control of cotton gins and the ansport of cotton in order to prevent adulteration of superior owths, and the inter-mixture of seeds of improved with improved varieties. It is perhaps significant that there is w more Indian cotton to be found on the Liverpool market an before the War, and the difference in the price it realises as mpared with American has almost disappeared. The total op of Indian cotton has now reached 6,000,000 bales of 400 lb. ch, as compared with a pre-War quinquennial average of 000,000 bales. A great deal of the extra cotton grown goes to Japanese and Chinese mills. It is intended to apply the me principles of inter-provincial co-operation to the still more fficult problem of cattle improvement. The Tamil proverb, the calf of the good cow dies," gives a scarcely exaggerated ea of Indian backwardness in the science of cattle-breeding.

An extension of the irrigated area is the most effective of all easures of famine prevention. The area annually irrigated by vernment works has now reached some 28,000,000 ac., which not much less than the total cultivated area of Great Britain. e area irrigated by wells and other privately owned sources is out 21,000,000 acres. The two greatest irrigation schemes e world has ever known are being carried out in the Indus sin, the Sutlej valley scheme and the Lloyd (Sukkur) barrage. e way for the former was prepared by the Triple Canal proj- t, sanctioned in 1905 and completed in 1917. The surplus ters of the Jhelum are held up by a head weir, and carried thwards by a canal to the Chenab, part being used to water large area between these rivers, but most being poured into Chenab above the intake of the old Chenab canal. The mand on Chenab water being thus reduced, some 20 m. higher a new head weir on that river has been constructed, which ters a great area between the Chenab and Ravi, and, crossing Ravi river, passes on to water the northwestern half of the wer Bari Doab, which is land lying between the Ravi and Sut- . Altogether over 1,700,000 ac. are annually irrigated by the als; and the execution of the project makes it possible to lise the Sutlej river, not only to complete the irrigation of the ri Doab, but also to irrigate a great area on the southeastern e of the Sutlej.

y the Sutlej valley scheme four head weirs are being con- ucted on that river, three above and four below its junction h the Chenab; 2,075,000 ac. will receive a perennial supply water; 3,033,000 ac. a controlled supply from the beginning April to the middle of October. The new canals will super- e a number of "inundation canals," which give a somewhat ertain supply from May to Sept.; and also will bring into tivation 3,750,000 ac. of desert waste. An interesting ture of the work is that mechanical excavators are being d because of shortage of labour.

t Sukkur, where the combined five rivers of the Punjab enter nde through a narrow gorge, the Lloyd barrage is being built, 25 ft. long between the faces of the regulators on either side, ich will control the flow of water into seven great canals. en fully developed the area annually irrigated will approach 00,000 ac., considerably more than the whole cultivated a of Egypt. As a necessary corollary the port of Karachi, of ich the trade has already nearly quintupled since 1897, will further developed by harbour works at a cost of £2,000,000.

owhere in India outside the Indus basin is there scope for rks of equal magnitude, but a great scheme is being carried for the irrigation of Oudh, by canal fed from the Sarda river. s project has been under contemplation for 50 years, but has n in abeyance because of the opposition of the Oudh land- ers (taluqdars). They have now altered their views as a lt of the experience of 1918, and the increasing cost, due to g wages, of well irrigation. The area to be irrigated is mated at 1,700,000 acres. In Madras even older schemes planned by Sir A. T. Cotton, the great pioneer of scientific al irrigation in India, have been revived, for great storage rvoirs in the Cauvery, Bhavani, Tangabhadra and Kistna rivers; and the Cauvery scheme has been sanctioned. All over India smaller works are being planned, debated and put into execution. (*See* IRRIGATION.)

Co-operation.—The policy of active encouragement of rural credit banks on the Raiffeisen plan, as the most effective means of remedying the chronic indebtedness of cultivators and improving the business side of agriculture, was adopted, after long discussion, by the Act of 1904. Registrars of co-operative societies were appointed for the different provinces, to draft model rules, register, inspect and audit the accounts of co-operative banks, and also to carry on propaganda and education in co-operative principles. In 1912 an amending Act was passed, as the result of eight years' experience; and also to extend the official encouragement to co-operation in other fields. The number of registered societies increased from 5,432 in 1911 to 61,106 in 1924; the membership from 308,000 to 2,314,000; the capital employed from Rs. 227 lakhs to Rs. 4,053 lakhs[1] (about £30,000,000). The great majority of the societies are village banks; but there are 522 "Central Banks" situated in towns, which gather in deposits, supply funds to the rural banks in their neighbourhood, and act as links between them. There are also "Apex" banks, for the provinces of Madras, Bombay, Bengal, Bihar and Orissa, Burma, the Central Provinces, Assam and Mysore. Encouraging progress is being made by societies for purchase and sale; sales to members aggregating Rs. 113 lakhs in 1924 and purchases from members Rs. 93 lakhs. There were 442 cattle insurance societies, with 6,693 members, a small but very hopeful beginning; and there is a promising movement in urban areas to use the principle of co-operation in house building and milk supply.

MANUFACTURING INDUSTRIES

On the basis of the number of people who are employed hand-loom weaving is still by far the greatest of Indian non-agricultural industries. The census of 1921 found very nearly 2,000,000 hand-looms at work, and the actual number was probably considerably greater. The Indian Industrial Commission (1916–8) discovered that the consumption of mill-spun yarn by hand-loom weavers increased by about 30% in the two decades before the War, which would more than compensate for the diminution in the output of hand-spun yarn. The War itself helped the weaver, Indian mills not being able to make up adequately the deficiency of imported cloth; so also did the very high prices of mill-woven cloth after the Armistice. But from 1922 onwards weavers' difficulties have greatly increased. The development of mill manufacture in China has deprived the Japanese mills of part of their Chinese market, and caused them to make greater efforts to dispose of their output in India. In the fierce and very equal competition which so ensues between Indian and Japanese mills, it is the hand-loom weavers who suffer most. In some districts after a struggle to live on less than subsistence earnings, they have been compelled to abandon their hereditary calling; in others, where the level of skill and enterprise is higher, they have given up cotton weaving for silk, or textures with gold or silver thread interwoven, which are called in India "lace work." The industry as a whole shows a surprising degree of vitality, fly-shuttles, which increase a weaver's output from 20 to 100%, have been adopted widely, and so also have simple machines for winding and warping, owned and used co-operatively.

Out of some 1,400,000 workers in factories of all sorts, about one-quarter are employed in cotton-mills, and some 80,000 in cotton gins and presses. This industry has had very considerable vicissitudes, but taking bad years with good, it has been prosperous and progressive. The total Indian consumption of mill-woven cloth is much the same now as in the years immediately preceding the War, in spite of the very great increase of price. But whereas before the War Indian mills supplied just under 30% of this production, their share has risen (1924–5) to 52%; while the share of the United Kingdom has fallen from 68·5% to 42·5, Japan now getting 4% of the market. On the other hand Indian mills have lost in China their chief foreign market. The supremacy of Bengal in jute is more firmly established than ever; nearly two-thirds of the jute grown is consumed by the Bengal mills, as compared with less than half before the War; so that Bengal now produces about twice as great a bulk of jute manufactured goods, mainly in the form of gunny bags, hessian cloth and cordage, as all the rest of the world. Such industries as leather tanning, paper manufacture, brewing, woollen manufacture, which are of considerable though minor importance, were greatly stimulated by War conditions, and maintain part of the advance so won.

---

[1] Lakh = 100,000 rupees; crore = 10,000,000 rupees.

The two most notable new enterprises launched in the five years immediately preceding the outbreak of War were projects of the late Mr. J. N. Tata, which were brought to fruition by his sons and their partners after his death in 1904. The Tata Iron and Steel Company was successfully launched in 1907 with Indian capital; it began operations in 1908 and produced iron first in 1911. When the World War broke out it was in a position to be of great service both in Mesopotamia and in other war theatres; and, since the military requirements were for steel, the company converted into steel as much as possible of the iron it produced, though the sale of iron in the open market would have been much more profitable. Dividends of 20% on the ordinary and 290% on the deferred shares were paid in 1917 and 1918; again in 1920 and 1921 ordinary shareholders got 16% and deferred shareholders 200%; but since 1922 no dividends have been paid except preference shares; and the heavy fall in the price of steel caused by intense international competition compelled the company to seek governmental aid. Various other attempts have been made in India to produce steel on modern lines; and in the boom period after the Armistice a number of schemes for exploiting the extraordinarily rich and abundant ore deposits of Orissa for this purpose were floated; the chief result of which was to increase the potential output of the Bengal Iron Company. The Tata Iron and Steel Company is the only one actually producing steel.

Equally notable was the Tata project of utilising the heavy rainfall on the Western Ghats to supply Bombay with electric power. In order that power should be available throughout the year it was necessary to create great storage reservoirs on the Deccan tableland. The first completed was at Lonavla, whence there is a fall of 1,725 ft. to the power-house at Khopoli. The works were formally opened on Feb. 8 1915. The Andhra valley project with its artificial lake further to the north, was initiated in 1916 and completed in 1922, and supplies 100,000 horsepower. It is being followed by the Nila-Mula scheme to the south of Lonavla, expected to supply 150,000 H.P., and preliminary work is being done on the Koyna Valley project, still further to the south, to yield 350,000 horsepower. The original purpose of these schemes was to make the Bombay mills independent of coal; but as the amount of power available has increased, it is becoming possible also to revolutionise the methods of transit and consequently the conditions of housing of Bombay. By the electrification of the railways in the immediate neighbourhood of Bombay it is hoped that third-class fares may be reduced to a rate of 11 m. for one anna (approximately one penny). This will make effective the work of the Bombay Improvement Trust, which is charged with the duty of reclaiming the islands to the north of Bombay and converting them into residential and industrial areas, thus making it possible for the most prosperous, but also the most terribly congested, city in India to expand to healthy dimensions.

The close of the World War was marked by a great outburst of speculation. The aggregate authorised capital of new joint stock companies floated in the year 1919–20 alone was Rs. 281 crores, whereas the paid-up capital of all registered companies in existence in 1914 was only 75 crores. Subsequent liquidations were heavy. The most important of the new projects which failed to realise expectations was the Tata Industrial Bank, the shares of which were being bought eagerly in the early part of 1920 at a high premium. Its object was to finance new industries on much the same lines as those followed by the "D Banks" in Germany; but after a short run it was amalgamated with Bombay Central Bank, which does ordinary banking busin the capital being considerably written down.

Banking.—On the other hand an important step towards organisation of a more complete and effective banking syst for India was taken in 1920 by the amalgamation of the Pre dency Banks of Bengal, Bombay and Madras into the Imper Bank of India. The Imperial bank was authorised to establis branch in London, which had not been allowed the Presiden Banks, and its London Branch takes over from the Bank England the business which the latter had previously d for the Govt. of India. The Imperial Bank has also been quired to open 100 new local branches to supplement the branches of its three constituents. A great deal more remains be done to knit together the various sorts of banks operating India into a sound and efficient system. There was a heavy m tality among Indian joint stock banks in 1913–7. The cau of this weakness still in large measure remain, and it must regarded as a factor retarding the progress of India towards complete financial autonomy.

THE GOVERNMENT AND INDUSTRY

Since 1910 there has been a change of policy in relation to dustry. In that year the principle of *laissez-faire* was asserted Lord Morley's despatch refusing assent to the plans of Madras Govt. for the encouragement of new industries, incidentally sentencing the Madras Department of Industr to temporary impotence. This department had been built step by step since Dec. 1897 by the initiative and under the c trol of Sir (then Mr.) Alfred Chatterton. At a total net cost £33,000 a prosperous manufacture of aluminium hollow-w had been established, the use of oil engines for pumping wa for irrigation popularised, well-boring carried on extensively, use of the fly-shuttle, automatic dobbies and subsidiary machi introduced among hand-loom weavers, and other import work accomplished. A similar policy had been initiated in United Provinces by Sir John Hewett; and there also it dropped in consequence of Lord Morley's adverse judgment the case of Madras. The outbreak of War brought a change the attitude of the India Office, and in May 1916 the Ind Industrial Commission was appointed to report on poss means of direct governmental encouragement of industry incompatible with the existing fiscal system. Its positive rec mendations were numerous and varied. Departments of dustry were in consequence re-created in Madras and United Provinces, established also in the other provinces, under the reformed constitution, put in the charge of Ind ministers.

Tariffs.—The reservation excluding the existing fiscal syst from review was only temporary. The Reform of the Cons tution was speedily followed by the appointment in 1921 of the Indian Fiscal Commission, which reported in fav of "rapid industrialisation by means of discriminating prot tion." In accordance with that recommendation an Ind Tariff Board was appointed in July 1923, to report on the ind tries referred to it which had applied for protection. The f and most important of these was steel, and the Tariff Bo recommended that bounties should be paid on the producti of heavy steel rails and fish plates on a descending scale beg ning at Rs. 32 per ton, and that specific duties roughly equival to 30% *ad valorem* (*e.g.*, Rs. 40 per ton on steel rods) should levied on other forms of British or other imported steel. T assistance not being sufficient to enable the Tata Iron and St Company to manufacture steel at a profit, an additional boun of Rs. 20 per ton on 70% of the monthly ingot production voted for the period from Oct. 1 1924 to Sept. 30 1925; and it subsequently decided that this bounty should be continued the diminished rate of Rs. 12 per ton till March 31 1927. 1925 also an old controversy was concluded by the resolve the Government to abolish the excise duty of 3½% *ad valorem* cotton cloth woven in Indian mills. Hence the duty of 11% imported cloth becomes undisguisedly protective.

abour Organisations.—The post-War period has seen a re- rkable increase of class consciousness among Indian urban rkers. Trade unionism on British lines made its first appear- e during the War in Madras, the pioneer society, the Madras bour Union, being a fairly solid organisation of the cotton- l operatives, which quickly found imitators among the alu- ium workers, the employees of the oil companies and others. e great rise of prices and the industrial boom of 1919 furnished most favourable possible conditions for a rapid advance of de unionism; increased wages were necessary, employers e most anxious to avoid stoppages, but they were not in all es ready to grant increases in proportion to the rise of prices ept under pressure, for fear the rise in price might be only porary.

ombay was the chief storm centre. The cotton operatives in ticular showed unsuspected staying power, and not only se- ed advances during the boom which meant an increase in as well as nominal wages, but also, in 1925, won a more re- kable victory in resisting successfully a reduction of wages ing the slump. Indian trade unions are still largely dependent he help of outsiders as organisers, and the success of particu- unions mainly depends on the single-mindedness with which se voluntary associates work for the material benefit of the nbers. There can be little doubt that in the future trade onism will prove a permanent and growing element in Indian strial life.

abour Legislation.—India was represented at the Interna- al Labour Conference at Washington, which was followed an "All India Industrial Welfare Congress" held in Bom- in April 1922. Important labour legislation was enacted in same year. The Factories Act of 1922, which came into force July 1, raised the age of admission for children from 9 to 12, full time work from 14 to 15, prohibited night work for wom- and enacted for all workers a maximum day's work of 11 rs and a maximum week of 60 hours. The Mines Act forbade employment of children and young persons below ground, le still permitting that of women, and limited the week's k to 60 hours above ground and 54 hours below. The Work- 's Compensation Act of the same year was a very carefully ted measure providing, on conditions designed to minimise ation, for compensation for death or accident for 3,000,000 in- trial workers. The contention that long hours of labour are e tolerable and justifiable under Indian than under European ditions springs from interested motives, and is not based upon al fact.

ailways.—In 1907 the route mileage of Indian railways open raffic reached 30,000 m., of which over 15,000 m. was standard ") gauge, and most of the remainder metre gauge. On March 925 the mileage was 38,269 m., of which 18,781 m. were standard ge. At that date 1,200 m. were under construction and 1,084 m. dition had been sanctioned. A great deal of unfavourable criti- has been levelled against the railway policy—or, rather, policies the Indian Govt., with special justification on the counts of of enterprise, vacillation and undue complexity. But the broad remains that nearly 40,000 m. have been constructed with a tal liability of £500,000,000, which convey passengers at an age rate very little over one farthing (3·74 pies) per mile, and ls at an average rate of one half-penny (6 pies) per ton per mile. eover, they make profits which are sufficient to meet all in- st charges and also to make substantial contributions to the nue of the country.

nportant changes are now taking place in railway administration. relations between the Railway Department and the general ad- istration are being altered to give the railways more financial onsibility and independence; on the termination of the leases of East Indian Railway and the Great Indian Peninsula Railway I. R. and G. I. P.), together comprising nearly 5,000 m., the king of these two lines was taken over by the State; and the em of departmental management is being superseded by divi- al organisation, which was tried successfully first on the Great an Peninsula Railway.

oreign Trade.—In the years immediately preceding the War an foreign trade made rapid progress. Very high freights and t difficulty in securing cargo space during the War necessarily ced the volume of sea-borne traffic very greatly; but the impera- need of belligerent countries for many sorts of Indian produce ed prices to rise so much that the money value of the goods ied was not greatly altered. The exports of private merchandise from India were valued at Rs. 249 crores in 1913–4 and at Rs. 253 crores in 1918–9; imports at Rs. 183 crores and Rs. 169 crores respectively. In 1924–5 the value of the exports went up to Rs. 398 crores and of imports to Rs. 243 crores. These figures disguise rather than reveal the essential facts with regard to the changes in Indian foreign trade. There has been a considerable reduction in the volume of imports, most marked in cotton goods and other textiles; but from this decline, in spite of protective duties, iron and steel have been exempt, the increase in Indian production being no greater than the increase in Indian demand; and there has been a very great increase in the imports of machinery and mill work. Other imports which have greatly increased are mineral oil and motor-cars. The volume of exports is now at least as high a level as before the War; but the character has considerably altered. Less grain is being exported and more tea; much less raw jute and a great deal more manufactured; the export of raw cotton has increased, and so has that of cloth, particularly coloured piece-goods, but the export of yarn has greatly declined.

India has in fact become much more self-sufficing with regard to manufactures, and less disposed to export food and raw materials except where, as in the case of cotton, high prices and increased production make export specially profitable. The causes of this change are partly to be found in higher freights and higher import duties; partly also in the changed condition of world trade as a whole, regarded as an interchange of manufactures for foodstuffs and raw materials, in consequence of which the Indian peasantry get only a small increase of price for most of the things they sell, but have to pay a great deal more for what they buy. But it is also partly due to Indian progress in manufacturing equipment and industrial organisation.

(G. Sl.)

Summary Statistics

		1913–4	1923–4
Area under cultivation		(million ac.) 219·2	222·5
Area under forest		(million ac.) 82·6	86·0
Yield of rice		(million tons) 28·8	28·2
Yield of wheat		(million tons) 8·4	9·7

VI. NATIONAL AND PROVINCIAL FINANCE[1]

The Indian revenues are largely dependent on the seasonal rains. If the monsoons are weak and the crops fail, land revenue has to be remitted or its collection postponed, railway receipts fall off, the agricultural population consumes less, the Customs and Excise revenue declines, heavy expenditure is incurred in the relief of distress, exports diminish and the exchanges move against India, increasing the cost of meeting her obligations abroad. Good and bad seasons tend to occur in cycles. Lord Hardinge's viceroyalty started in a good cycle. The four years 1910–4 were years of financial prosperity. The ordinary revenues were expanding, and there were large windfalls in the opium receipts, due to the high prices which the Chinese were offering during the last few years of a trade that was being steadily reduced under an agreement for the complete cessation of the export of opium from India to China in a given period. It thus became possible to make large grants to the provinces for education and public health.

The War Period.—With the outbreak of war in 1914, Indian finance enlarged its experiences. Direct expenditure on the War was at first small, as India was charged only with the normal cost of her armies engaged on the various fronts; and the pre-War military charges of about £20,000,000 rose only gradually to £29,000,000 in 1917–8. But India's external trade was dislocated, and her railway and Customs receipts suffered accordingly; so that the first two years were marked by deficits. In 1916–7 additional taxation was imposed, but the export of war material had now begun to assume large proportions, and agriculture was also flourishing. In 1917 the financial position was sufficiently strong to justify the Indian Govt., with the approval of the Legislative Council, in making a contribution of £100,000,000 to the home government towards the cost of the War; and in 1918 a further contribution was volunteered, which had, however, to be subsequently revised after the Afghan War, and was adjusted finally at about £14,000,000. In 1917–8 taxation was again increased, but such was the activity of trade and the general prosperity of the country that a surplus of £8,000,000 was realised.

Then the tide turned, and for a series of years the national accounts failed to balance. The old standard of military expenditure was doubled; the Afghan War of 1919 and the succeeding troubles in Waziristan threw a heavy burden on the revenues; a weak monsoon in 1920 was followed by considerable agricultural distress; the trade boom which had been stimulated by the heavy manufacture of war material slowly exhausted itself, and exchange was crumbling; while a rapid rise in the cost of living left the government with no option but to make some corresponding increase in the wages of its army of employees. The deficits were met by temporary expedients which had recently been strangers to the Indian financial system—dipping into balances, accommodation from the banks and borrowing for revenue purposes.

The New System.—With 1921–2 started a new era. The estimates of the central administration were entirely separated from those of the provinces; and the former were for the first time subjected, with reservations already explained, to the vote of a popular Assembly, which took the place of the old and comparatively complacent Legislative Council. In an attempt to balance the budget, the Customs tariff was raised from a general *ad valorem* rate of 7½% to 11%, with 20% on certain luxury articles; postal and railway rates were enhanced, and the taxation on incomes stiffened. But a severe trade depression had now set in, and there had been two feeble monsoons. The year closed with over £22,000,000 to the bad; and, what was even worse, the government was compelled to budget for a further deficit in 1922–3, the legislature having rejected several of its proposals, among which a rise in the salt duty was prominent, for improving the revenue.

But sharp retrenchment had now become imperative; and in the winter of 1922 a special committee under Lord Inchcape attacked the whole problem of expenditure. Their recommen tions,[2] comprehensive and drastic, extending to military as we civil charges, were put into effect, so far as time admitted, in estimates which were laid before the Assembly in March for the ensuing year. To complete the rehabilitation of the b get, the government proposed to double the salt tax (roug from a farthing to a half-penny per pound); and when this prop was defeated in the Assembly the Viceroy restored it by the of his exceptional powers, thereby provoking a fierce polit controversy. The result justified the means, for a marked vival in trade combined with the financial reforms to sho small surplus at the end of 1923–4. The budget for the succ ing year was wrecked as the result of an extremist demons tion in the Assembly; and the Viceroy had again to interpose arbitrary authority, though he was careful to certify expendit at a minimum figure which allowed the salt tax to revert t old rate of 1¼ rupees per 82 pounds.

Railways.—Despite this untoward start, 1924–5 went trade steadily improved, and with it exchange revived, the ending with a substantial surplus. Its course was marked by important financial changes. On the one hand, the financ the railways was definitely separated from the general accou and now became a self-regulating entity instead of a handm to the general revenues and the sport of their vicissitudes. railway budget is now framed upon considerations of a consist railway policy, and its only connection with the national bud is that it is bound to make an annual contribution from its ceipts, calculated at 1% on the capital liability of the penultim year, plus one-fifth of the surplus profits, if any, in that yea

The Protective Tariff.—The second landmark of 1924 was enforcement in practice of the policy of discriminative protec which a tariff committee of some years earlier[3] had recommen for the Steel Industry Protection Act of 1924 imposed import du which were clearly expected to be prohibitive on certain articles ufactured from steel, while it granted bounties on heavy steel r fishplates and railway wagons manufactured in India. Hardly the Act passed when the bounties were found inadequate to t purpose and were enhanced. Schemes for similar protection to o domestic industries continued to be formulated, and the whole tr of Indian political opinion is in their support. The following year another fiscal measure of great, if more sentimental, importa The excise duty on cotton goods manufactured in India, which originally been imposed to counterbalance the tariff on impo cottons, and which had for many years been resented as a sacrifi Indian interests to Lancashire, was at last abolished from De 1925, in fulfilment of an arrangement which had been reache settlement of a disastrous strike among the cotton-mill worker Bombay. The accounts for 1925–6 seemed likely to close on the side; and the estimates for 1926–7 again presumed a surplus, altho the law of averages would point to the near approach of a s monsoon.

Budget of 1925–6.—The main constituents of the central bud if 1925–6 be taken as a sample, are as follows:—

Source	Revenue	Object	Expend ture
	£ millions		£ million
Customs	30·9	Defence (net)	37·5
Taxes on income	11·6	Debt services	12·1
Salt	4·6	Civil administration	7·3
Opium	2·4	Other charges	8·3
Railways (net)	3·5		65·2
Currency and mint	2·7	Surplus	·5
Provincial contributions	4·5		
Other receipts	5·5		
	65·7		65·7

The customs tariff, which long stood on a purely revenue foot with a 5% charge all round, is now divided into protective, protective and general sections. The protective section is at pre restricted to manufactured iron and steel, but the so-called protective duties include luxury rates, such as 25% on sugar 75% on cigars, while the *ad valorem* duties in the general sect range from 2½% to 30%. There is a low export tariff on jute, hi rice and tea. The taxation on incomes includes a supertax, and attention has been given to perfecting what used to be a most satisfactory source of revenue; all income from agriculture is exem ıe production of salt, whether from mines, lakes or sea water, is a overnment monopoly, and the duty on it used to be treated as the serve or balancing factor in the Indian budget; but popular presre now seems likely to standardise it at 1¼ rupees per maund, or out one farthing per pound. Opium is a steadily diminishing ure; in 1918 there were 207,000 ac. under cultivation for the opium ppy, in 1924 there were only 133,000 ac.; exports to the Chinese ırket were extinguished, and in May 1926, it was announced that exports of every kind are to cease, even to foreign governments. ıis cessation is to be by a tenth each year.

---

[1] In this section the rupee is taken throughout at a conventional value of 16 pence. The full story of exchange is discussed later.

Provincial Finance.—Obviously, however, the figures quoted ove do not cover the whole field of the state's revenue and exnditure. Quite £50,000,000 of receipts, representing their collecns of land and irrigation revenue, excise, stamps and forest inne, appear in the budgets of the nine provincial governments. A nilar sum is expended by them on their administrative business, stice, education, public works, police and gaols, public health, etc. is clear-cut demarcation of financial responsibility was part of the w constitution. From 1833 up to 1921 the accounts of the imperial d provincial authorities had been amalgamated; in the budget of 21-2 they were separated. The local governments now receive the ld of the sources which they administer, and are responsible for the penditure of the provincial departments, both reserved and transred. By far the most important of their resources is the land enue, which, together with the cognate receipts from irrigation, npose more than half the total budget provision of the provinces. inions differ as to whether it is a rent or a tax; but it is a legacy m Mogul rule, and proceeds on the assumption that all the land he property of the Crown.

In Bengal and Northern India a class of intermediary landlords s been gradually evolved, and they are assessed on their rent rolls; Madras and Bombay the revenue is assessed directly upon the t or cultivating occupant, with reference to the estimated output his land. The whole system is being caught up into the region of itical argument, as problems of much importance are beginning to ide popular feeling, *e.g.*, the permanency or otherwise of the essments, the security of tenure in the landlord provinces and the ht of the State to determine rents. In order to enable local governnts to discharge their new functions, they have been given powers taxation, scheduled so as not to invade the sphere earmarked for requirements of the central Government. They have been horised, for the first time under the new constitution, to raise ns, either through the central Government or independently, and ıe of the provinces have already borrowed, for works of improvent such as irrigation and city development schemes.

rovincial Contributions.—The severance of provincial finance n the general accounts brought to the front a problem inherent in federal constitutions, even if they are as embryonic as in India lay. In former years the central Government used to finance itin part by taking a share of the revenues collected in the proves; and incidentally it thereby kept alive its right to intervene in management of the sources from which such revenues flowed. en on the road to provincial autonomy a point was reached at ch this right was curtailed, and the provincial revenues were lited wholly to the provincial exchequers, it became apparent t the central Government had no longer the control of funds icient for its own business. In India the customs, salt, opium and railway receipts, income tax, etc., when once they ceased to be plemented by a share of the provincial land revenue, stamps and ise receipts, etc., proved inadequate to meet the demands of nce, the public debt and the other liabilities reserved by the cen-Government.

nder this compulsion, and arguing that the provinces should itably] contribute to the defence of the country, the Govt. ndia (with the full concurrence of the Select Joint Committee of liament) imposed a levy on the provinces. The total sum which y were asked to pay was about £6,500,000. It was distributed ng the provinces in rough ratio to the advantage which each had ned by ceasing to share its provincial revenues with the central ernment; and hopes were entertained that the central finances ıld improve with sufficient rapidity to enable those tributes to be dually reduced and in a short period completely remitted. Adsity defeated those hopes, and the reduction has been slow and gular. Meanwhile the provincial legislatures, with rare exceptions, e fastened on the arrangement as the main cause of their own ncial stringency, and have magnified a not unreasonable and ely temporary expedient into an intolerable grievance, under er of which there has been a tendency to evade the imposition of ation that might have balanced their own budgets. Several local rnments claim, in addition to their own separate revenues, a e of the taxation upon income collected within their boundaries; some concession on this point has been yielded as an exception to general rule of separate resources, by giving each province an wance of three pies for every rupee by which the income assessed ıin the province exceeds the income that was similarly assessed 920-1.

ocal Finance.—The 772 municipalities of British India have the osal of an annual revenue of over £9,000,000, exclusive of Governt grants and borrowings; and the district and local boards have a nal revenue of about £8,000,000. Both classes of bodies have been endowed by the 1919 constitution with a financial independence commensurate in its degree with that of the provinces. The six port trusts have statutory powers for their own business, and control an income in the neighbourhood of £5,000,000; Bombay and Calcutta in particular having raised considerable loans which rank only second in the Indian market to Government securities.

Indebtedness of India.—The Govt. of India borrows both locally in rupees and in England in sterling—the former now to a very much larger extent than before the War. The position at the beginning of the War was thus described officially:—

Out of a total debt equivalent to £274,000,000 outstanding at the end of March 1914, only about £13,000,000 represented ordinary or unproductive debt. The annual interest on the latter was £750,000 only, and on the productive debt about £8,500,000, so that our total interest charges amounted to some £9,250,000. Railways and irrigation works in the same year yielded us a return of £15,250,000. Thus we had left some £6,000,000 of clear revenue from our great capital undertakings, after meeting interest charges on our entire public debt.

This was the result of a long, careful policy of converting unproductive debt, *i.e.*, money raised for military purposes and the like, into productive debt, by the device of short borrowing for the capital required on railways and irrigation. It had put India into a very strong position to face the changes brought about by the War. The War debt, inclusive of the gifts to the home exchequer, the loans for the expenditure on the Afghan War and subsequent frontier operations, as well as the borrowing necessitated by the series of budget deficits, all went to swell the volume of the unproductive debt; and on March 31 1926 the total indebtedness of India was:—

In India	Crores of rupees
Loans	368·35
Borrowed from the paper currency reserve	49·65
Other obligations	93·27
	511·27
In England	£ millions
Loans	266·43
Other obligations	76·05
	342·48

Of the total it was considered that about 23% was unproductive. The productive loans included the capital liabilities for irrigation, which were taken over by the provinces when that subject became wholly provincial. The "other obligations" are mostly unfunded debt, such as post-office cash certificates and savings bank accumulations, provident funds, etc.; while in England £57,500,000 are accounted for by capitalising liabilities which are being liquidated by certain terminable railway annuities. In lieu of a general sinking fund an arrangement was started in 1924 by which an annual sum is appropriated from revenue for the reduction or avoidance of debt; it is calculated at four crores plus one-eightieth of the amount by which the outstanding debt of the year exceeds the debt outstanding on March 31 1923.

VII. CURRENCY AND EXCHANGE

The foundation of the currency system is the rupee (16 annas or 192 pies), a coin weighing 180 gr. and containing 165 gr. of pure silver. The subsidiary coinage comprises pieces of silver, nickel and bronze; all being legal tender up to one rupee only, except the 8-anna piece, which, like the rupee itself, is legal tender without limit. The sovereign also circulates as freely as Gresham's law permits. Alongside of these is a paper currency, at first of slow and lingering growth, in the form of Government currency notes, the higher denominations of which are, strictly speaking, encashable only in the currency circle (usually an area of one or two provinces) for which they were printed. The favourite notes are for 1, 5, 10 and 100 rupees; but there are also others for 2½, 20, 50, 500, 1,000 and 10,000 rupees. The note circulation as a whole is backed, as to more than one-half, by a reserve of gold and silver, and as to the balance by Government securities held partly in England and partly in India, with a margin for seasonal expansion based on trade bills up to a strictly defined amount.

The exchange value of the rupee follows the ordinary economic law and depends on India's trade balance with the outer world. When there is a big surplus of exports, import bills are at a premium and the rupee rises in terms of sterling; when in bad years exports decline and there is a relative glut of import bills, the rupee falls in terms of sterling. The operation of this law, however, assumes a fairly constant adjustment of the volume of currency to the requirements of trade. If there were no restriction on the output of rupees, the gold value of the coin would tend to fluctuate with the gold value of silver. Up to 1873, although the Indian mints were open, the rupee continued steady at an exchange value of 2s.; then the price of silver began to tumble until the rupee dropped almost to 1s., and so disastrous were the consequences to the finances of the country that in 1893 it was decided to close the mint to free coinage and establish a "managed" currency, with the rupee as a token coin. By this policy an equilibrium was sought.

The Rupee During the War.—By the beginning of the War this system had reached considerable strength. The rupee had been given by law a parity of 16d., and trade conditions had never put it beyond the power of the Government to maintain the exchange at approximately that figure. The machinery for managing the currency was simple. The Indian Govt. bought silver and coined rupees to meet the requirements of the country. So long as silver was under 43d. an oz. there was a profit on the operation, which was placed to the Gold Standard Reserve and (except for a brief and partial diversion) invested in sterling securities in London. Against this reserve the Govt. of India could sell sterling drafts (technically known as " reverse Councils "), if the exchange value of the rupee threatened to fall. On the other hand, if it were rising, the Secretary of State could increase his normal sales of rupee drafts on India (technically known as " Councils "), which would be met out of the Govt. of India's reserves of rupees or, if necessary, by fresh minting. Should this fail to check the rising exchange, it was generally possible to count on a free importation of private gold which would either pass into circulation or be presented to the Government for the purchase of rupees. All these arrangements were working smoothly in 1914. The Gold Standard Reserve stood at £26,000,000, all except £4,000,000 being held in gold or gold securities in England. A continued favourable balance of trade had encouraged the import of gold, of which £70,000,000 worth had been absorbed between 1910 and 1914. The Paper Currency Reserve had £24,000,000 in gold or gold securities, and the note circulation had risen to 66 crores (£44,000,000).

With the War came new and disturbing demands. India was called upon to supply the British Govt. and the Allies with immense quantities of raw materials, manufactured goods and foodstuffs for War purposes, and also to provide funds in India and in countries where Indian troops were fighting. The Indian Govt. had therefore to disburse a rupee currency in very large amounts. The home Government repaid its debts by credits in London, but the Indian Govt. required money in India, and the difficulty was to remit specie. Gold was unobtainable, silver was becoming very scarce in the London and American markets. The Indian Govt. was therefore compelled to increase the note issue without a corresponding increase of rupees held against the notes. The notes were convertible and their encashment drained away the reserve stock of rupees. The time drew near when either inconvertibility must be declared or silver obtained in large quantities for coinage. So seriously were the political effects of inconvertibility regarded that the Government strained every nerve to avert it. The 1-rupee and 2½-rupee notes were invented; the import and export of the precious metals were put under the strictest regulation; and the mints worked night and day.

The Pittman Act.—Yet, with the world shortage of silver, inconvertibility was all but reached in 1918, when help came from the Govt. of the United States. Congress was prevailed upon to pass the Pittman Act as an emergency measure. This Act enabled the Government to borrow from the Treasury the greater part of the dollar reserve of 375,000,000 oz., held as security for silver certificates. The United States Govt., as soon as it obtained this authority, allowed the Indian Govt. to purchase 200,000,000 oz. of silver dollars on terms much below the current market prices, and accelerated the dispatch of the metal to India. From July 1918 onwards American silver began to arrive in large quantities and was coined into rupees. For some months the new money went out of the reserves as fast as it was coined, but by Dec. 1918 the convertibility of the note issue was secured. Between March 1916 and March 1920 the output of the mints was represented by the enormous quantity of 1,390 million new rupees (£93,000,000) as currency.

Throughout this struggle another anxiety grew apace, in the risk of being unable to maintain the rupee as a token coin at its statutory parity with sterling. Sterling was depreciating and silver was rapidly appreciating. From its pre-War price of about 26d. per oz., silver advanced to an average of 31d. in 1916, of 48d. in 1918 and of 61d. in 1920, touching the figure of 89d. in Feb. of that year. As the conversion of the rupee into bullion became profitable when silver touched 43d., the rapid rise beyond that figure led to a wholesale melting down of rupees for clandestine export; and the Government was forced to protect itself by hurriedly pushing up the parity of the rupee until it stood at 2s. 4d. in Dec. 1919, while for a short time private remittances fetched over 2s. 10d.

The Indian Currency Committee.—The whole problem was then referred to a committee of currency and banking experts sitting in London. Reporting early in 1920, this body (with one notable dissentient) recommended[1] that the rupee should be correlated to gold, and not to sterling, which by that time had depreciated in relation to gold and had no certain value, and that it should be given a new statutory ratio equivalent to one-tenth of the gold contained in a sovereign. This would give the rupee the equivalence of 2s. when the pound sterling returned to parity with the sovereign. The committee were of opinion that the price of silver expressed in pence would remain at the point that would make the retention of a 1s. 4d. rupee impossible unless the coin itself was diminished in weight or fineness. This alternative they rejected. They thought that, having regard to the higher price levels of the world, India would still able to maintain a favourable trade balance with a 2s. rupee, that any consequent readjustment of rupee prices of Indian exp staples would be to the advantage of the Indian consumer by act as a drag on internal prices.

The Indian Govt. accepted the committee's recommendation, in Sept. 1920 the Indian Coinage Act established the new ratio of rupee as one-tenth of a gold pound. But currency was alre laughing at the law. There was a rush of remittances to Engla and at the same time the export trade of India fell off. In comn with other countries whose exports consist of raw materials, In found the demand for its produce suddenly dry up. The former plus of exports gave place during the second half of 1920 to a la adverse trade balance which had to be liquidated by bills on Lond Exchange persistently dropped from 2s. 6d. the rupee, which in first months of 1920 roughly represented the parity of one-tenth gold sovereign, to below 1s. 4d. in the early part of 1921, and price of silver receded to 32d. the ounce. The Government ende oured to maintain the rupee at its new exchange value by sel drafts on their resources in London, but economic forces were strong for them, and after they had diminished their gold holding this way by well over £50,000,000, they abandoned the struggle left exchange to find its own level. It steadily dropped to betw 1s. 4d. and 1s. 5d., when the sale of Councils was tentatively rec menced, at whatever they could fetch without regard to the st tory parity. In the hope of ending this anomaly, another curre committee was appointed towards the end of 1925, when the ru had become fairly steady near 1s. 6d.; it had not reported w Lord Reading resigned. Meanwhile, the position had improve readiness for any further attempt to control exchange. The G Standard Reserve had reached £40,000,000 of sterling securitie point at which it was decided that further accretions should be ployed in reducing the rupee securities in the Paper Curre Reserve. The latter in March 1924 contained £68,000,000 in and silver, and over £9,000,000 in sterling securities.

The strenuous efforts made during the War to preserve the vertibility of the currency notes were rewarded by a rapid expan of their popularity. The circulation (66 crores) of March 1914 alr trebled in the next 10 years, touching 186 crores in March 1 notwithstanding the practical disappearance of the 2½-rupee and 20-rupee notes. In 1920 the whole system was improved by Paper Currency Amendment Act of that year, which allowe unlimited note issue provided a metallic basis of 50% was obser required the gold backing to be held in India and introduced principle of a certain definite expansion of the note issue during busy season against trade bills of a durance not exceeding 90 d Before the note circulation became so firmly established as it no several attempts were made to lighten the task of supplying I with silver currency by the employment of gold. Among them the opening of a branch of the British Mint at Bombay, intende coin sovereigns and 15-rupee gold pieces. Like all other sin experiments, it was defeated by the immediate disappearance of into the hoards of the people. Nearly 3,500,000 gold coins minted at Bombay in 1918–9, and work was then abandoned.

BIBLIOGRAPHY.—In contrast with the former scarcity of books on India, they now abound; and the following is necessaril arbitrary selection from the newer works. The standard all-r text-book is *The Imperial Gazetteer of India*, vol. 1 to 4. Add to the *Statistical Abstract of British India from 1914–5 to 19* (Cmd. 2534 of 1925); and the reports to Parliament on the M and Material Progress of India, now published as *India in* *1919, 1920, 1921–2, 1922–3, 1923–4* and *1924–5*, written by Rushbrook Williams, and bringing a full narrative of current ev up to date.

Historical: Sir Verney Lovett's *India* in the " Nations of To-d series (1923) is the latest authoritative work. Sir V. Chirol's tr should be studied: *Indian Unrest* (1910); *India Old and New* (1 and " India " in *The Modern World* series (1926).

Constitutional and Political: The key book is the *Repor* *Indian Constitutional Reforms* (Cmd. 9109 of 1918) by the E. S. Montagu and Lord Chelmsford. With it read *Dyarch* L. Curtis (Oxford, 1920), which contains the text of the Sel Committee and the Act of 1919. Other works are E. A. Horne, *Political System of British India* (Oxford, 1922); Sir C. Ilbert, *Government of India* (Oxford, 1922); Ilbert and Meston, *The Constitution of India* (1923).

Problems of To-day: Sir Verney Lovett, *History of the In* *National Movement* (1920); Bishop Whitehead, *Indian Pro* (1924), and as studies in Indian psychology, Lord Ronalds trilogy, *Lands of the Thunderbolt, India a Bird's-eye View*, an *Heart of Aryavarta*, published by Constable in 1923–4, respecti

Economic and Finance: Dr. P. P. Pillai, *Economic Conditio* *India* (1925) and Gyan Chand, *The Financial System of* (1926). (M

lgriculture.—In 1925 there were 195,785 farms of five acres
l over, the total farm land area, which forms 94% of the total
a of the state, being 91,917,780 acres. The assessed value in
4 of all farm property was $2,218,034,991. The chief crops
corn, wheat and oats which produced in 1924, 100,317,606,
353,066 and 58,782,554 bushels respectively. Hay and rye
also produced. In 1924 the area under tobacco cultivation
; 20,695 ac., yielding 18,362,243 pounds valued at $3,057,000.
ge quantities of tomatoes are grown besides other vegetables
l fruits of all sorts. The number of livestock reported on
ı. 1 1925 was 557,472 horses, 103,235 mules, 1,296,163 cattle,
,000 sheep and 3,006,242 swine.

lineral Products.—Coal mining was the principal industry,
340,000 short tons being mined in 1924, the state continuing
rank sixth in this respect. Petroleum wells yielded in the
ıe year 935,000 barrels valued at $1,700,000. The large stone
.rries of Monroe and Lawrence counties produced 70% of the
estone used in the United States for building, the 1923 output
ıg valued at $17,692,112. Indiana oblitic limestone is used in
rly every state and in foreign countries. Indiana has valu-
: clays, shales and kaolin, and is sixth among the states in
ımic production, her clay products in 1923 being valued at
,643,128. Drainage tiles, encaustic tiles, fire-proofing, terra-
a, sewer pipe and stove linings are other important clay
lucts. Pottery products include earthenware, stoneware,
te granite, semiporcelain, sanitary ware and porcelain elec-
al ware.

ducation.—In 1921 the state increased the tax levy for com-
ı-school support as well as for the support of the higher edu-
onal institutions and provision for teachers' pensions was
:ted. There was a tax levy of five cents on each $100 of tax-
: property for the support of the three higher educational
itutions of the state, producing about $2,750,000, and a levy
fraction of a cent for vocational education producing yearly
ut $115,000. In 1924 $64,696,230 was spent on education.
925 the tax levy for higher education was repealed and the
e state schools received special appropriations.

onstitution and Government.—During the decade 1910–20
e was much discussion over amending the constitution of
state, a difficult undertaking under the constitution of 1851,
much as amendment requires the assent of two legislatures
ratification by a majority of the electors. In 1914 an effort
made to bring about a state convention to revise the con-
ıtion. A conference was held at the state university, out of
:h grew the Constitutional Convention League, whose pur-
it was to bring about such a convention. Under the in-
nce of this league, while the Legislature refused to call a
stitutional convention, it agreed to submit to the voters by
rendum in 1916 the question whether such a convention
ıld be held. The proposal was voted down by a large ma-
y, partly because of the expense involved, partly from fear
adical innovations. The vote for the convention was, how-
, so large that two Assemblies approved a series of 13 amend-
ts which were submitted to the voters in 1921. All the
ndments but one were rejected.

uring the 12 years 1913–25 much legislation was passed
nding governmental functions. Only a summary of this
be attempted here: In 1913 an inheritance tax was imposed. In 1915 laws were enacted dealing with industrial aid to the blind; flood prevention; the direct primary for state nominations; workmen's compensation for injuries; and arbitration in industrial disputes. In 1917 a Prohibition Act was passed, made more drastic in 1925 by provisions making the possession of intoxicants a penal offence and the Eighteenth (Prohibition) Federal Amendment was ratified Jan. 14 1919. Provision was also made for a system of state parks, with a commission charged with reforestation and the conservation of natural resources; and a Highway Commission was created charged with building a complete system of state roads, for which purpose, in 1923, a gasoline tax of 2 cents a gallon was provided, increased to 3 cents in 1925, bringing to the commission for road building from $6,000,000 to $7,000,000 annually. In 1921 a state budget system was adopted, and cities were allowed, at their option, to provide for city planning and to adopt the city manager or commission form of city government. In 1921 the Riley Hospital for children, a memorial gift from citizens to the state, was established under the care of the university. In 1921 the university took over the only Dental College in the state.

Since 1909 the governors of the state have been as follows: Thomas R. Marshall (Dem.), 1909–13; Samuel Moffet Ralston (Dem.), 1913–7; James Putnam Goodrich (Rep.), 1917–21; Warren T. McCray (Rep.), 1921–3; Emmet F. Branch (Rep.), 1923–5; Ed. Jackson (Rep.), 1925–

INDIANAPOLIS, Ind., U.S.A. (*see* 14.427), which claims to be the largest city in the world not situated on navigable water, ranked 21st in size in 1920, with a population of 314,194, of whom 34,678 were negroes and 16,958 foreign-born. In 1925 the official estimate was 358,819. The population increased 34·5% between 1910 and 1920, but the number of foreign-born decreased 14·2%. The area was increased from 33 sq. m. in 1910 to 43·5 sq. m. in 1920, and to 49·5 in 1925. The output of its factories was valued at $126,313,000 in 1909; $398,667,000 in 1919; $262,285,896 in 1921; and $346,858,158 in 1923, when there were 783 establishments within the city limits employing 45,818 workers. The leading industries were meat-packing, manufacture of automobiles and automobile accessories, metal trades and machine shops, canning, manufacture of wearing apparel and printing.

After the disastrous Ohio Valley floods of 1913, a concrete levee 40 ft. high was built along the west side of the White river with a 60 ft. driveway on the top. This was completed in 1916. A new street lighting system was installed in 1915 and improved from time to time. A $3,000,000 sewage purification plant was installed in 1925. The elevation of the railway tracks entering the Union station was begun in 1917, and the old Union dépôt was rebuilt and enlarged into an attractive and commodious station. A city plan commission was established in 1919, and a zoning ordinance adopted in 1922. The park area had been increased by 1925 to 2,544 ac. and there were 53 m. of boulevard and 46 city playgrounds. The War Memorial Building, costing $10,000,000, which houses the national headquarters of the American Legion, was nearing completion in 1925. The cost of living is relatively low in Indianapolis (94% of the average for 31 American cities in Dec. 1924), as would be expected from its exceptional transportation facilities and its favourable location with respect to agricultural and manufactured products and coal mines.

INDIAN LITERATURE.—In Europe literature is, as regards its subjects, largely international, and any new fashion, such as romanticism, pessimism, the psychological novel, the detective novel, is quickly propagated. The individual qualities of prominent writers are soon known, directly or through translations, and evoke responses more or less obvious. Moreover, the similarity of social conditions and outlook lends interest to the same problems everywhere, and international science causes them to be approached from the same points of view.

English and European Forms.—In India the bulk of the educated public is acquainted with English; new English publications are quickly available in the libraries and reading rooms; any new book which has obtained a vogue in England will soon be reviewed in India and be a subject of articles in magazines. Moreover, India has in England, America, France, Germany and elsewhere numerous students, and some journalists, who are living the lives of those countries and sharing their interests; and we have also to reckon with the presence in India of a considerable community of English and other administrators, teachers, missionaries and business men. Consequently, there is a very large output of writings which in spirit and manner, and often in subject, are not properly Indian, but either international or what may be termed "colonial." In Bengal alone over 1,000 publications in English (irrespective of bilinguals) are produced annually, and there are over 100 English periodicals of different kinds. We might mention in addition the large number of works by Indians and officials or ex-officials in India which are actually published in England.

A second department of Indian literature consists of writings in Indian languages which are based upon European models or deeply affected by such. Here we have a great mass of fiction, biography, history, much drama, lyric poetry, travels, political and social pamphleteering and an immense magazine literature, modes which are simply copied from European models. In this sphere we should not overlook the considerable number of actual translations or adaptations of individual works in English, French and so forth. This might be described as the vernacular literature of absorption.

A third stage is represented by that vernacular literature which, while it has absorbed European influences, has yet recovered an Indian outlook and temper, whether in the course of nature or in obedience to the strong reactionary feeling. Already in the 'eighties of the 19th century Bengal had produced a novelist, Bankim Chandra Chatterjee, whose work exhibits a creative synthesis of the new and the old; and at the present day the Bengālī language has, irrespective of its outstanding representative, Sir Rabindranath Tagore, a modern literature conscious of an independent inspiration.

A fourth department is constituted by the continuance of ancient modes and conceptions.

Linguistic Distribution.—Apart from the influence of particular centres, such as universities, the literature is very unevenly distributed. The matter must be stated in terms of languages. In the field of Assamese, Oriya, Bihārī, Punjābī, Sindhī, Nepālī and Kāshmīrī, the Rājasthānī dialects and Malayālam of southern India, the old modes may be said to prevail with little innovation.

High Hindī, in regard to which the same might a few years ago have been said, is rapidly equipping itself with literary and scientific compositions on modern lines. Urdū, the chief organ of Mahommedans in Hindustan, the Panjāb and Central India, is further advanced in the same direction. The two chief languages of the Bombay Presidency, Gujarātī and Marāthī, more especially the former, have a considerable modernising literature. The Telugu of Madras is perhaps not so far advanced; but Tamil has a large productivity, hardly second to Bengālī. Special educational efforts have led to the publication of a fair number of manuals in Kanarese (Mysore), as also in Gujarātī (Baroda) and Urdū (Bhopal and Hyderabad); but other Indian States are not productive on modern lines.

English.—For publications in English about the same proportions hold as for modernised vernacular literature. English works are, indeed, far more prevalent in the provincial capitals, whereas those in the vernacular abound in the less anglicised districts, Gujarātī, for instance, favouring Ahmadābād, Marāthī Poona. The non-modernised literature is also published in all considerable places.

Classical and Other Languages.—The chief classical langua
India, Sanskrit, is represented by editions of two kinds, thos
old Indian lines with or without commentaries in Sanskrit
modern vernaculars, and those with commentaries in Eng
The former are very widely published in the Deva-nāgarī c
acter, or in Bengālī, or in Gujarātī or in the south Indian al
bets, sometimes even in the Panjābī or Urdū; and there
various combinations of these scripts. Editions on Euro
lines appear for the most part in the provincial or state cap
or in the university towns. New original works in Sans
are not infrequent in the sphere of oriental philosophy, ph
ogy, science and religion; occasionally there appear new p
and dramas of considerable extent and literary merit; and t
are also Sanskrit periodicals, including even a daily newspa

Other classical languages are: (1) Prākrit, usually that o
Jains and published in the Bombay province or in the Hind
Mārwārī-speaking areas; (2) the Buddist Pāli, rare in India
the Tibetan, published at Calcutta and Darjeeling; (4)
Pahlavī of the Parsees, published in Pahlavī or Gujarātī s
in the Bombay Presidency; (5) the Arabic, appearing chief
Delhi, Lucknow, Hyderabad; (6) the Persian, more occasi
Many of the vernacular languages also have their old or clas
periods, and prominently the Dravidian group, Tamil, Tel
Kanarese and Malayālam; re-editions of their classical w
are very frequent, and for the most part they are publi
within the areas of the respective vernaculars.

Translations of Sanskrit works are innumerable in nearl
the vernaculars, the *Bhagavad-gītā* for instance being re
duced many times every year; and some degree of the s
favour extends to some of the local classics, the Hindī poem
Tulasī-dāsa, and the Hindī *Bhaktamāla.* Among modern H
writers Swami Vivekānanda, Bankim Chandra Chatterjee
Rabīndranāth Tagore, Romesh Chunder Dutt and Harapr
Sāstrī have also a popularity in several languages; and po
novels, in particular the favourite *Chandrakāntā* (from
Hindī), and its imitators, are frequently translated. Portug
publications appear at Goa, French at Pondicherry and Chan
nagore; the Roman Catholic missions print some brochure
Latin, and there is even an Italian periodical issued from M
galore (*La Missione di Mangalore*).

Alphabets.—The literature of India is, therefore, hi
polyglot, while individual publications are very often bilin
at least. The alphabetic aspect of the matter has also
partly indicated. In spite of the attention which has
given to the possibility of a common script for India,
advocating the Roman, some the Devanāgarī (which h
Hindī periodical devoted to its interest), there is no eviden
progress toward simplification; there is a certain amoun
Roman-Urdū, and Roman is usually employed for the Kon
form of Marāthī and for the rendering of previously unwr
languages. But in general each leading language holds t
traditional script. Sometimes it has more than one; for
Mahommedan writes his Panjābī or Hindī or Malayālam
Tamil (not, however, his "Musalmānī-Bengālī") in the U
character, with any necessary modifications. The Sikh
write his Sindhī in the Gurumuphi of the Panjāb. Bilin
books are therefore unusually also bialphabetic (except
regards the above-mentioned case of the Sanskrit, or sim
cases with Pahlavī and Gujarātī, or Arabic texts with Persia
Urdū); and this adds to the multiform appearance of
Indian literary output, already sufficiently variegated, eve
we overlook such characters as the Multānī, Modī, Ka
Savara, which indeed are rarely printed, or the numerous
writings appearing in philological works. The format of
book is not seldom that of the old Indian *pothī*, sometimes
Bengal) even printed on palm leaves; while the Panjāb G
muphi and the Mahommedan Arabic are much less often prin
than lithographed from handwritten originals.

SUBJECTS AND FORMS

To begin with the lowest stratum, we must note the existe
in India of an extensive, really popular literature in verse.

parts of India, but especially perhaps in the Punjāb, in the narese country and in the Tamil area, there is a constant duction of songs and ballads, provoked by any notable asion, such as a prize fight, a flood or calamity, a crime, a gedy, a personality or social event, an act of administration; se have a real, though probably in general a brief, life upon lips of the people, who sing them over their work or in their ial gatherings. Of late years this form has been largely used political propaganda, innumerable small collections of tional songs" appearing in all the chief languages. There also many collections of songs for special occasions; *Garbhī* gs for women, marriage songs, songs for the Holī (spring) ival and other celebrations, boat songs for aquatic sports in ssa and Bengal and so forth. At certain times of the year Mahommedans put forth vast quantities of "verses" in nour of Mahomet or dirges for Hasan and Husain. Religion a large share in this poetic activity: songs in honour of shna (especially in Hindustan, Bengāl and Orissa, but also in jarāt and Southern India), of Caitanya (*kīrttans* in Bengal), Kārttikeya, Ganeśa, Dattātreya, Vithobā (in the Marāthī a); songs for pilgrims to or at the various shrines (innumere in the Telugu and Tamil country); songs for temple rites; ections of Jain hymns; and the many publications of Chris- sects, which in some cases (Roman Catholic) even deign follow Indian models. Not all this popular literature is verse, since there are occasions when sacred stories in prose *ari-kathās* and the like) are narrated in or near the temples.

ral Preservation of the Classics.—An oral existence appertains to a good part of the various classical writings of India. is is the case not only with Sanskrit works such as the Mahābata and Rāmāyana, some parts of the Purānas, and some ries such as those of Sāvitrī and Hariśchandra, but also to the sics of the several vernaculars. Not to mention the substance stories and legends, the texts of such poets as Kabīr and asī-dāsa in the Hindī area; Vidyāpati, Govind Dās and many ers in Bengal; Narsinh Mehta, Mīrā Bāī and Prēmānand in jarātī; Nāmdēv and Tukārām in the Marāthī country, lā in Kashmir; the Sūfī poets of Sindh; the Vaishnava and va saints and moralists of the Tamil country, are very familiar the lips of ordinary people in their respective areas, and, ides being used in education, are frequently re-edited. In Punjāb some parts of the Sikh *Granth* are similarly used.

he Drama.—On the borderland between the oral and the rary we have the drama. In India it was indigenous in many ns, from the heroic down to the morality, miracle play, the e, the shadow or puppet show. Except in the extreme south ndia, it would seem that the popular forms of representation e been more or less levelled out. The ordinary play, proed chiefly in Calcutta, Bombay and Madras, is similar to European forms—melodrama, social sketch, burlesque, blem play (the old man and the young wife, the modern ng man or woman and so forth), love story: it is generally rspersed with verses, and these are often separately published popular use. The more literary drama, still sometimes in skrit, takes its subjects chiefly from old Indian poetry and nd, and is not seldom an adaptation of a particular Sanskrit k (the *Śakuntalā*, the *Mahābhārata* and *Rāmāyana* or sodes therein, and so forth). The choice is to some extent cted by local celebrity, and occasionally a political application may be suspected.

agazines.—The pabulum of the ordinary reader in India is nished by the magazine, containing essays, biographies and criptions, short stories and serials, notes and not rarely strations. The total output is enormous; for in addition to diversity of languages we have to reckon with the division he Hindus into castes with their separate interests and claims. ortant castes prefer an organ (or competing organs) of their , which, along with the ordinary magazine material, will tilate any matters having a communal bearing. This literae, therefore, presents no ordinary problem to the bibliogers; somewhere in India it should be sedulously collected preserved, on account of the special biographical and sociological items which it contains. Schools and colleges have their organs (usually, however, in English). The missionary agencies, including the Salvation Army, issue innumerable periodicals of all grades, both in English and in the vernacular. Trades and the business world, professions (teaching, medicine, law, astrology, and so on), and grades of official service all contribute to the mass of vernacular organs. There are further a *Hindī Punch*, a *Hindī Graphic*, a Gujarātī and Marāthī *Tit-Bits*, and short story magazines; music and the stage are also represented by popular periodicals. Special interests, such as the cause of women, social service, co-operation, labour, economics, business, arts and sciences, travel, boy-scouting are similarly equipped. The chief vernaculars have usually at least one literary periodical of a fairly high type. In some cases they have flourished during long periods: the *Sentamil* of Madras is in its 24th volume, the Hindī *Saravatī* in its 25th, the Bengali *Bhāratī* in its 49th, the Gujarātī *Samālochak* in its 30th, the Marāthī *Vividhajñānavistara* in its 56th. The Urdū *Humāyun* also is of some standing.

Indian Poetry.—Modern Indian poetry, excepting translations and adaptations of old Sanskrit works and themes, is usually in the form of short lyrics issued in small collections. Larger productions are for the most part collected works of single authors, or anthologies or the outcome of literary Eisteddfods. In the Hindī area the ballad of old style attains a greater length, as do Tamil *Kāvyas* on classical models. The poetry is generally erotic, ethical, philosophical or religious; but the satirical and controversial, and also, as we have seen, the political, claim a place. The verse forms are usually the traditional ones: only Bengālī, it appears, manifests original power in this direction.

Fiction.—Fiction on European lines is making rapid headway in India, and it is supplanting the old romantic tales, at least so far as prose is concerned. The Punjab may still reprint its *Hīr* and *Ranjhā*, *Rāja Rasālu*, etc., the Sindh its *Sassī* and *Punnūn*, the Urdū language its *Lailī* and *Majnūn*, and Hindī the tales of *Bhartarī* and *Gopīchand*. The novel is popular both in the form of the short story and of more substantial narratives; and it reflects all the varieties of subjects which have a vogue in English, historical, social, romantic, adventurous (including the detective novel). A new feature is the translation of well-known (including English) novels into several languages and the immense vogue of such popular stories as that of the Hindī *Chandrakāntā*.

Religious Literature.—Indian religious literature, in so far as it is not lyrical, philosophical, argumentative or philological, consists mainly of manuals of ritual for daily life (*dinacaryā*) or for particular occasions (marriage, burial, times and seasons, pilgrimages, vows), and of the stories therewith associated; for instance, the story of the Tulasī plant and that of Satya-Nārāyana are constantly reproduced. Benares takes a prominent part in such publications. Since each section, from the Vedic *Śākhās* downwards, must have its separate rituals, it results that the number of such publications is very great. Especially in southern India the innumerable local shrines have their little manuals, each setting forth the sacred legend and the rites to be observed. In the case of the orthodox and older sects, which have sacred texts in Sanskrit, this literature is often bilingual (at least), reproducing or copiously citing the originals.

We pass to a consideration of the activity in the reproduction of old canonical texts, with or without commentaries, for the purpose not of ritual but of study and edification. This accounts for a great mass of republication: in the Punjāb, for instance, there is a steady stream of thick volumes of *Selections from the Ādi-granth*. There are some valuable series of such canonical texts; the Jains have several and the Madhva doctrine of south India and the sect of the Mahārājas in Bombay have thus made accessible their chief writings. Important sects have usually one or more periodical organs, which, amid other matter, publish and comment upon their authoritative books. Many religious texts are, of course, not the property of any particular sect, and are therefore variously reproduced; and from these we can hardly separate those which are of a philosophical rather than of a religious character: such are the Vedānta writings, the Madras periodical *Vedānta-dīpikai*, and other philosophical journals; of wider scope, the *Siddhānta-dīpikai* and the Marāthī *Tattvajñāna-vistara.* There are English periodicals belonging to one or the other of the above two groups: such are the *Vedānta-kesarī* of Madras, the Ahmadī *Review of Religions* and *The Theosophist* (which also has vernacular allies). Modern philosophy is represented by the Calcutta Philosophical Society, and by a now extinct Indian Philosophical Review published during several years in Baroda.

Philology.—Philology of a more general character is no longer in India restricted to one or two classical languages, Sanskrit, Prākrit, Tamil, Pahlavī, Persian, Arabic. There are societies which devote themselves to the publication of old texts in the existing vernaculars. The Bangīya Sāhitya Parishat, with its *Pattrikā* and its series of separate old Bengālī texts, has a very honourable record. The Tamil Sangam of Madura (which issues the *Sentamil*) is likewise distinguished. There are now other Sāhitya Parishats in the province of Bengal, and for Telugu also there is the Āndhra Sāhitya Parishat. For Hindī there are the Nāgari-prachārini Sabhā and certain Mandalas; for the Panjāb the Khālsā Tract Society; in Gujarāt, where societies for publication seem to flourish, the oldest is the Gujarāt Vernacular Society, while there is also a Sāhitya Parishat, and a Sāhitya-vardhana Society; in Marāthī an important series of editions of old poetry was published under the title *Kāvya-samgraha.* In literary history there are very important and extensive works by Rai Saheb Dineschandra Sen (Bengālī); Sir G. Grierson and the Misra brothers (Hindī); G. M. Tripāthī and K. M. Jhāverī (Gujarātī); Prof. W. B. Patwardhan (Marāthī); and Vīresalingam Pantulu (Telugu).

As to the general philological activity of India, it is hardly possible to draw any clear line between indigenous scholarship and that affected by European methods: the main aim and procedure of scholarship are the same everywhere, and whether a commentary is in Sanskrit or Bengālī or English seems to make little essential difference. Only comparative philology is new to India. This philological activity, wherewith is associated the investigation of archaeology and pre-British history, and from which we may exclude the astounding output of educational work up to the level of university text-books, is connected chiefly with organisations of some kind. The Govt. of India itself maintains an Archaeological Survey, which publishes annual reports in the several provinces and at headquarters, and splendid quarto and folio monographs on special matters, as well as a periodical relating to Epigraphy (*see* ARCHAEOLOGY: *India*). This example is followed by Indian States, Mysore, Travancore, Hyderabad, Kashmir. Several provincial governments have published catalogues of Sanskrit MSS. (Bengal, the United Provinces, Bombay, Madras, the Central Provinces); States, small and great, Kashmir, Nepal, Baroda, Mysore, Travancore, Alwar, Bhaunagar, have taken their part. Important series of Sanskrit or Arabic texts, too, are officially edited in Bombay, Mysore, Travancore, Kashmir, Hyderabad, Baroda.

After the Governments we may mention the universities, colleges and libraries as active in the publication of texts and researches (the universities of Calcutta, Madras, Lahore, the Benares Sanskrit college, the Maharajahs' College, Vizianagram, the Bankipur public library). Important journals are issued by societies (the Asiatic Society of Bengal, which has also published under the title *Bibliotheca India* a vast collection of Sanskrit, Arabic, Persian and Tibetan texts; the Bombay branch of the Royal Asiatic Society, the Mythic Society of Bangalore, the Bihar and Orissa Research Society, the Hyderabad Archaeological Society, the Bhandarkar Oriental Institute); and some, like the *Sanskrit Research*, the *South Indian Research* and the *Jain Purātattva*, are occasionally started independently or by religious bodies. The books issued by authors, editors, or individual publishers are, however, more numerous and on the whole the Indian publication of philological, historical and archaeological matter relating to pre-British India quite
dwarfs in bulk all that is done outside. Much is highly mer
rious, and some of it is fully equal to the best productio
Europe. The monumental *Linguistic Survey of India*, edite
Sir G. Grierson for the Govt. of India, is now (1926) al
completed (*see* PHILOLOGY).

History.—For educational purposes and general read
many short histories of India, of England and of other coun
are produced both in English and in the vernaculars.
original research and independent judgment will be found ch
in the few first-hand histories of particular states and dynas
and with a few exceptions (such as the Marātha research
Rai Bahadur, D. B. Parasnis and the volumes of Mar
records published by the Marātha Historical Society of Po
the volumes of Professor Sarkar concerning Aurangzeb,
biography of Jahāngīr and the *Journal of Indian Hist*
published by the Allahabad University School of Indian Hist
the works on South India by Professor Kumāraswāmy Aiyan
Subrahmanyam Aujar and a few others) in the works of Engl
men. The valuable monographs produced in Europe or I
by Indian scholars relate for the most part to ancient times,
are less historical than philological. Many volumes of rec
and calendars in English have been published by local gove
ments; the gazetteers also are replete with historical infor
tion not absorbed in formal histories; and there are several so
ties, the Bengal Historical Society, the Panjāb Histor
Society and the United Provinces Historical Society, wh
journals are composed of original matter.

Biography.—Biography, including autobiography, is now p
ular in India, taking chiefly the form of short mem
which in the case of princes and of important religious lea
such as Debendra Nāth Tagore and Dayananda Sarasvatī,
attain a considerable length; so also in the case of histor
personages, Sivājī, Jahāngīr and others. A very favourite fo
of which there are old examples, is the serial biography, cont
ing lives of saints, lives of famous women, hierarchical, dyn
and family biographies. Valuable work of this kind has b
done in regard to the Tamil and Telugu saints and poets,
the poets of Bengāl and Gujarāt. Small volumes of "pr
reminiscences" have been published by political offenders,
the number of short "lives" of popular heroes, such as
Tilak, Mr. Gokhale and Mr. Gandhi, is beyond count
The old form of biography in verse is still favoured in rela
to saintly and historical characters: naturally, it has aims o
than information and research. Many Indians, from prin
downwards, have written accounts of their travels, whether
England, on the continent of Europe, in America or in o
countries, including the Far East. But India itself furni
rich material and occasions for travellers' experiences, especia
in connection with its shrines and pilgrimages, so that such tit
as *Bhārata-bhramana* quite naturally recur. (F. W. TH.)

INDIANS, NORTH AMERICAN (*see* 14.452).—The Indians
no longer warlike nor to any extent resistant of the white m
methods for their civilisation.

I. IN THE UNITED STATES

The United States assumes that health, education and indus
are essential to the Indian's self-support and citizenship. Acc
ingly, the Federal policy is to hasten his advancement and p
tect his personal and property rights. By Act of June 2 192
Indians within U.S. territory not already citizens were made
Under the administration of the Bureau of Indian Affairs th
are provided health supervisors, school and agency physici
field matrons, nurses and travelling dentists, whose duties de
nitely pertain to the physical welfare of the Indians, and h
pitalisation is widely maintained against all forms of disease.

Education.—For education, the Federal Govt. conducts
day schools, 59 reservation and 18 non-reservation boardin
schools, having an attendance of over 25,000 pupils. The cour
of study prescribed combines scholastic with such industri
training as is well adapted to Indian needs and temperamen
The aim is to prepare girls to become good housewives an
mothers, and to fit boys for practical farming or to give the

knowledge and practice in mechanical industries as will to skilled workmanship. The day-schools carry six grades, the boarding-schools six, nine or 12 grades. The object of latter is to embrace six elementary grades, a junior high rse of three grades, and a senior high course of three addi- al grades. From the more advanced schools students may uire full training in such chosen trade or occupation as may lify them to engage in remunerative pursuits upon their luation. In all Federal schools prominence is given to hy- e, to moral conduct, to religious culture in any Christian omination and to the practice of thrift. State public schools e become accessible generally to Indian children, and in these ools there are over 34,000 enrolled. Over 7,000 are received ission and private schools. Approximately 87% of the Indian dren of the United States are enrolled in some school. There been a steady increase in the number who speak, read and e English.

o promote reservation industries there are maintained dem- tration and experimentation farms, and several hundred ners, stockmen and assistants are employed in giving prac- l instruction in modern methods of agriculture and the up- eding and handling of live stock. Loans have been made to rgetic Indians from tribal or public funds as initial capital, these measures have been generally successful. Special ention has been given to the reclamation of arid and semi-arid ian lands, resulting thus far in a total area of lands under structed works approximating 636,000 ac., with an ulti- e area approximating 1,370,000 acres. The annual crop ues derived from these irrigated lands are equal to all prior . Tribal herds of sheep and cattle have been maintained on umber of reservations with financial profit, but chiefly to ourage individual ownership and enterprise.

laska.—The affairs of the Alaskan natives are supervised by U.S. Bureau of Education. Eighty-five schools are conducted six superintendents, nine physicians, 27 nurses and 157 teachers. e hospitals are maintained. The work is carried on in 85 villages tered along the coast and on the great rivers. Imperfect trans- tation and climatic conditions render the service very difficult, the progress is substantial. Despite the heavy mortality from ase, the population has slowly increased to approximately 27,000. Bureau of Education has established three industrial schools, ated at Eklutna, 28 m. north of Anchorage, on the Alaska Rail- l, at Kanakanak, on Bristol Bay and at White Mountain, on river, 25 m. from Golovin, on Norton Sound. Instruction is en in carpentry, in boat-building, mechanical and marine engineer- for boys; and for the girls: home-making, nursing and sanita- . When the Alaska school service was established, about 1885, aborigines of Alaska were in primitive conditions, which have dually disappeared. In many of the villages, the old huts have n replaced by neat well-furnished houses. Many Indians are ployed by the great canneries of southern Alaska. They own l operate fleets of power-boats, which are of service in transport- fish from the fishing grounds to the canneries. Some find employ- nt in the mines, while others are pilots, trappers, storekeepers, gers or ivory carvers. In northwestern Alaska the reindeer ustry is the basic industry, introduced to furnish a vocation that rantees food, clothing and transportation. Herds were found in 6 near all of the principal native settlements of western Alaska l at various other points. So rapidly have the herds increased t the total number of reindeer in Alaska was in 1925 estimated at ,000, of which about 255,000 are owned by the natives.

General Progress.—Under the policies outlined, the North erican Indians have made unusual progress during the years o–26. Their population is greater than at any time in the ceding half-century. They depend less upon "medicine n" and more upon medical science and sanitation. As com- red with earlier periods, they are giving more attention to manent homes; are less nomadic and superstitious. The men are better housekeepers, and infant mortality is decreas- . The day of paint and feathers and blanket garb has almost sed away. The younger school-trained element is creating a v leadership, manifested in changing habits, customs, indus- l pursuits and social life. Marriage by tribal custom is yield- to legal rites, and crime is diminishing. Substantial advance- nt is noticeable in agricultural operations and stock raising, he use of modern machinery and methods and in large gains ndividual funds.

The acceptance by the Indians of American principles of government and civilisation was in some sense disclosed by the World War. In the United States the number of Indians in military service was more than 10,000, three-fourths of which represented voluntary enlistment. In Canada the number exceeded 4,000, all of whom entered voluntarily. The percentage of Indian male population of military age in the World War was probably equal to that of the whites thus engaged, and their proportion of volunteers even greater. They were distributed almost entirely in white organisations, and were highly commended by their officers. Indians ineligible for war duty were active in Red Cross and other relief work and responded to emergency demands for productive labour. (C. H. Bu.)

Comparative Information About the Indians in the United States, Exclusive of Alaska

Population and Citizenship	1911	1925
Population	322,715	349,595
Indians receiving allotments of land	164,215	245,521
Indian citizens of the United States	179,830	349,595
Educational and Vital Conditions	**1911**	**1925**
Indian children eligible for school	63,411	77,597
Indian children in Federal schools	23,647	25,706
Indian children in state public schools	11,000	34,452
Indian children in mission and private schools	4,750	7,280
Total Indian children in all schools	39,397	67,438
Capacity of all schools for Indians	43,015	64,910
Hospitals and sanatoria maintained	50	84
Capacity of hospitals and sanatoria	1,268	2,573
Indian patients treated	8,408	27,775
Indians given medical examination	42,645	83,306

II. IN CANADA

The Indians in Canada numbered in 1923 about 109,000 and are now slowly increasing. They are regarded as minors under the law and are administered by the Department of Indian Affairs under the Indian Act, whose aim is to promote the advancement of the Indians in the arts of civilisation. If, and when, enfranchised they lose the advantages of protection by the Department and are merged in the general population. Agents, 114 in number, have been appointed to encourage the Indians to settle in the Reserves set apart for them which amount to 4,911,259 ac., valued at $52,941,629. The capital of the Indian Trust fund on March 31 1923 amounted to $11,516,213. The attendance at the 340 schools provided for them was 66·5% of the pupils enrolled—6,931 boys and 6,792 girls. The total income of Indians for 1923 from all sources was estimated at $9,940,349.

INDO-CHINA, FRENCH (*see* 14.490), French colony in Asia, consisting of the colony of Cochin China (under a governor, with 20 provinces, each under an administrator); the four protectorates of Tongking (23 provinces), Annam (16 provinces), Cambodia (13 provinces), Laos (10 provinces), each with a *resident supérieur;* and the territory of Kwangchow Bay, leased from China for 99 years, under an *administrateur en chef.* Its area is 299,621 sq. m. and the population (1924) 19,624,000, of which 26,137 were Europeans (24,882 French) and 14,522,000 Annamese.

Political History and Administration.—Indo-China contributed two fighting and 17 labour battalions during the War, 48,900 other war workers and much war material. It contributed largely (Europeans and natives alike) to the war loans. Political troubles during the War were trifling, in spite of enemy agitation. The governor-general during the War was M. Ernest Roume. M. Alexandre Varenne, a Socialist Deputy, was appointed in Nov. 1925. His arrival coincided with the accession of a new emperor in Annam. Relations between the emperor and the French authorities were settled by the convention of Nov. 6 1925. The *résident supérieur* of Annam has been granted permanent authority by the emperor to consult the representatives of the people and to discuss with them any important reform or questions which may arise.

The powers of the governor-general have been reinforced by a decree of Sept. 2 1920. His local decrees (*arrêtés*) have real legislative force. He can dissolve or suspend the *conseil colonial.* He fixes taxes and contributions (except customs duties) leviable in the colony as a whole, or locally, with the advice of local authorities and vote of local chambers. The *conseil supérieur* (*see* 14.491) has been superseded since Oct. 24 1911, by a council of government with very similar duties and composition, and thus still almost entirely official; but it now includes *délégués* (elected by French votes) for Tongking, Annam and Cambodia; native representation is increased from four to five.

In Dec. 1924, the governor-general, Martin, announced a sweeping reorganisation of the whole system. The council will bear the name "congress of the Indo-Chinese union" and consist of 44 members (27 representing the French, 17 the native element) elected by the local elective assemblies of Cochin China, Tongking and North Annam, Annam and Cambodia and Laos. It will have extended financial powers. The old council and its committee will continue under new names and with reduced membership; the new congress will send delegates to both. M. Varenne will probably bring the system into force. The colonial council in Cochin China has been reorganised, its powers extended, and its electoral and native elements strengthened. Natives now have five-twelfths of the representation. The native franchise has been radically reorganised; it now includes all male native French subjects with a clean judicial bill who possess either a property qualification (payment of a land tax of 21 piastres, or a corresponding dealer's licence) or a capacity qualification gained by possession of educational diplomas, exercise of certain public functions, or "services rendered to France." This franchise gives the vote to very many small peasant proprietors; abolishes the headman oligarchies; and amounts to a far-reaching social and political revolution in the villages.

In the protectorates the councils have been democratised on similar lines and natives given an increased share in self-government. This is, it is true, limited mainly to budgetary and fiscal matters; but the change has worked smoothly; the natives have often given sound advice on technical questions. They are keenly interested in self-government, education, etc. There are also native provincial councils and native representation in the municipalities of the large towns. The system will be extended under M. Varenne.

Education and Culture.—The educational movement is parallel to the political, but as the province has over 2,000,000 children of school-going age much remains to be done. In 1924–5 primary and secondary French schools had an attendance of 2,525 (about half natives); the 3,395 Franco-native official schools, an attendance of 213,977; the private schools (native and missionary) one of 99,790, the expense on education being 6,000,000 piastres (1924). The 1917 public instruction code laid down the principle of the teaching of French, even in elementary schools, but there are reservations, defined in the *arrêté* of Sept. 18 1924. French is taught with the native tongue during the first three years of primary instruction, and is the obligatory teaching medium of the last two, which are, however, attended by only 23% of the native pupils. The "University of Indo-China" at Hanoï is a high school with many branches giving practical and theoretical training; it aims at turning out competent native assistants for the different French administrators, and training lawyers, planters, traders and manufacturers. Most of the students are Annamese. The *École Française d'Extrême Orient* at Hanoï, under the patronage of the *Institut de France*, conducts valuable research work in native art, history and language. It has a fine library and museums in Hanoï, Tourane, Saïgon and Phnom Penh, and has done epoch-making work in its *Inventaire* of Cambodian and Cham monuments, its excavation of the ruins of Angkor, etc. (see its two vols., *L'École Française d'Extrême Orient depuis son origine jusqu'à 1920* (1922) and its semi-annual *Bulletin*).

Budget.—The general budget, under 24,000,000 piastres in 1901, was 64,602,000 piastres in 1925, almost all drawn from indirect taxation. Local budgets (drawn from land tax, etc.) were 48,978,000 piastres. Each spent about 30% of receipts public works. Reimbursements to the French budget for m tary expenditure reached 10,000,000 fr. in 1925. The deb only 400,000,000 fr., absorbing 2·8% of the total revenue.

Defences.—The divisional general commanding troops in In China (Hanoï) has under him three brigadier-generals (To king two, Cochin China). Troops consist of two regime French Colonial Infantry (Tongking, Cochin China); two b talions of the Foreign Legion; two regiments artillery; detachments French gendarmes; two flying squadrons, wh also do excellent work in mapping and fiscal service. There four native regiments of tirailleurs in Tongking, one in Coc China. There are five "military territories" on the Chin frontier and in Laos. The medical service is relatively importa and helps in the general sanitary organisation. The navy under the command of a *capitaine de vaisseau* (Saïgon). local squadron has been reduced almost to nothing since War. There is question of handing the Saïgon Arsenal over t private enterprise.

Commerce, Agriculture, Industry.—Although there is stil plethora of French officials (about 4,600), especially in the lo ranks of the Customs and Excise and similar services, there over 3,000 French non-officials (males), traders, manufactur and planters. In 1922 there were from 250–300,000,000 invested in private French enterprises. Rice remains the sta product; 4,750,000 ac. in the Mekong Delta were under r in 1920. There were 62,500 ac. of rubber plantations and ot tropical plants were cultivated successfully. The anthrac mines of Hongay and Dongtrieu produce 1,000,000 tons an ally. The production of zinc (40,000 tons) and phospha (20,000 tons) is important. In 1925, 33,833 hands were enga in mining (329 Europeans). The presence of coal has given bi to a rapidly expanding industry in the Red river delta, wh there are large cement works, brick, tile and ceramic wor three naval yards (beside the Saïgon arsenal), two importa French river steamer companies, three large cotton spinni works and minor industries. Home industry (lace-making, et employs many native women. The piastre, worth 2·50 fr. bef the War, was in 1926 worth 15 fr.; but on a piastre basis, expo have increased by 77% since 1900, imports by 14% only. Si the end of the War exports are some 164,000,000 piastres an ally, imports 132,000,000, rice being the main article export (maximum, 2,325,000 tons in 1921). Imports to France fr Indo-China in 1925 were 612,000,000 fr., exports 760,000,00

Communications.—There are now 2,075 km. of railways. important line, 126 km. long, is planned which will run fr Tanap to Thakhek and link up Central Laos with Central nam. Tourist traffic is now possible and encouraged. Over 000,000 piastres were spent during the years 1919–25 on dredgi irrigation, etc., and 50,000,000 piastres on roads, of which the are now over 30,000 km. (11,000 metalled, 9,000 made possib for motors in the dry season).

BIBLIOGRAPHY I.—Official and semi-official publications: *nuaire général de l'Indochine* (Hanoï annual); *Rapports au Conseil Gouvernement* (annual); *Bulletin Economique de l'Indochine* (eve two months with monthly statistical annexes); *Bulletin de l'É Française d'Extrême-Orient* (bi-annual). Among the publications the school must be noted: *Inventaire archéologique de l'Indochi* 1. Monuments du Cambodge, 3 vol. with atlas by Lunet de Jonquière (Paris, Leroux 1902–12); 2. Monuments Chams l'Annam, 2 vol. by H. Parmentier (*ibid.*, 1909–18); *Bibliothe indosinica*, by H. Cordier, 4 vol. (Paris, Leroux 1912–5), an a mirable bibliography of books and papers on the whole Indochine Peninsula; *Mémoires du service géologique de l'Indochine* (Han Imprimerie d'Extrême-Orient); *Revue indochinoise*, 1925, xxvii year (*ibid.*); Henri Brenier, *Essai d'Atlas Statistique de l'Indochi Française* (Hanoï, 1914), 88 charts, 38 maps, with commentarie *Service géographique de l'Indochine*, Map Scales: 1/1,000,00 1/500,000; 1/100,000; 1/25,000 (deltas); *Bulletin des Amis du Vie Hué* (articles on Annamere history, archaeology and art); J. Galembert, *Les Administrations et les services publiques Indochino* (Hanoï, 1924); Henri Lecomte, Membre de l'Institut, *Flore Génér de l'Indochine* (Paris, in course of publication); *Les Bois d'Indochi* (in preparation 1926). II.—Non-official: Cl. Madrolle, *Guide l'Indochine*, 2 vol. (New ed., Paris, 1924); H. Russier and H. Brenie *L'Indochine Française* (Paris, A. Colin, 1910); C. B. Maybon an H. Russier, *Notions d'Annam* (Haïphong, 1916); Lt.-Colonel Abadi

s *Races du Haut Tonkin* (Paris, 1924); Henri Maître, *Les Jungles oï* (Paris, 1912); J. Commaille, *Guide aux ruines d'Angkor* (Paris, 12); Marquis de Barthélemy, *Mon Vieil Annam* (Recits de ıasse) (Paris, 1925); Marcel Bernamose, *Les arts décoratifs au Ton-ı* (Paris, 1922); Paul Collard, *Cambodge et Cambodgiens* (Paris, 25); Georges Groslier, *Recherches sur les Cambodgiens* (Paris, 1921); *gkor* (Paris, 1924). (H. Br.*)

INDUSTRIAL ASSURANCE: *see* INSURANCE, SOCIAL.

INDUSTRIAL EDUCATION.—In the United States special aining for industry in regularly organised courses is of recent igin. It was common before the World War and before re-ictive legislation checked the influx of immigrants from Europe American industries to secure most of their skilled workers m the Old World. The pressure of industrial competition l manufacturers to see that America must do something to in workers, and the labour situation during and since the ar led to a rapid expansion of industrial education. The War so led to a complete redistribution of the men and women o were engaged in industry and greatly stimulated agencies voted to the training of adults. The Federal Govt. attempted ring the period of demobilisation to provide for the industrial adjustment. Especially was the effort made to care for sabled and partially disabled soldiers by training them in rms of work suited to their physical and mental abilities.

The first serious effort in the United States to provide indus-ial education in public schools was made by the State of Mas-chusetts in 1905. A commission was appointed by the Gov-nor under the authority of the Legislature to make a report on e matter of industrial legislation. This commission was fol-wed by a second, and the final outcome in 1913 was a code of ws providing for state-aided and compulsory vocational edu-tion. In 1911 Wisconsin adopted a law creating for the state d for local districts, school boards in control of vocational ucation separate from those in charge of the common schools. is radical step has not been imitated in other states.

The Federal Board for Vocational Education.—In 1917 the ngress of the United States was persuaded by a group of in-strial managers and by a small group of educators, chiefly ose interested in the Massachusetts and Wisconsin experi-ents, to set up a Federal board known as the Federal Board for cational Education, which was the disbursing agent for a rge Federal appropriation to be distributed to the States on dollar-for-dollar arrangement for the purpose of encouraging dustrial courses, especially in high schools. This board is au-orised to supervise courses in agriculture, commercial subjects, me economics and industrial or trade courses. The latter are w provided in public schools either in all-day trade schools, all-day courses in technical high schools, in part-time courses continuation schools, in part-time courses on the co-operative an or in night schools, and in so-called extension classes or portunity schools, where workers come for training when not oc-pied in wage earning. Much of the industrial training outside the all-day schools is arranged so as to be available for adults.

Statistics.—The number of centres to which Federal support s been given in successive years and the registration in indus-ial courses in these centres are shown in the following tables:—

Trade and Industrial Schools

	Evening	Trade Extension	General Continuation	All-day
1918	300	341	. .	168
1920	435	119	322	199
1922	620	150	506	237
1924	776	238	582	279
1925	816	225	556	297

Number of Pupils Enrolled

	Evening	Trade Extension	General Continuation	All-day
1918	46,333	53,005	. .	18,596
1920	48,354	17,159	98,082	21,224
1922	66,477	33,106	167,911	31,390
1924	84,973	35,475	256,133	33,262
1925	86,540	30,400	265,335	39,666

Relation to General Education.—The tendency at the time the Federal Board for Vocational Education was organised was to make a sharp distinction between general education and academic education. This tendency was strengthened by the example of Germany, which was regarded before the War as the most successful nation in developing industrial education. The tendency in 1926 was to unite trade training and general education rather than separate them. Many high schools have made industrial courses a part of their regular programme. On the other hand, trade schools have found that it is necessary to include general courses if young people are to be properly trained for life in a democracy. *See* also COMMERCIAL EDUCATION. (C. H. J.)

INDUSTRIAL PSYCHOLOGY.—Industrial psychology may be defined as the study of the conduct of men and women in their capacity as wage earners. It aims at describing and explaining all those activities by means of which a person adjusts himself to his economic environment; hence it must take into account the fundamental elements of man's constitution, his innate tendencies and their expression in thought, feeling and action both on the conscious and unconscious level, as well as his acquired aptitudes. As yet, only a tentative beginning has been made, so that we are far from even an approximation to scientific generalisation.

HISTORY OF THE SCIENCE

The development of industrial psychology has been largely determined by its history. Prior to 1914, psychologists concerned themselves but little with industrial problems. A few writers occasionally saw a possible industrial application of some psychological generalisation; and in 1913 Münsterberg[1] made a more ambitious attempt. Industrial development had been governed by the claims of machinery, rather than of man. The enormous improvement in machinery during the 19th century, the studies made in the natural sciences, the growing knowledge of the mechanism of the body, all tended to focus general interest on man's likeness to a machine. The phrase "the human machine," which is rightly applied to part of his structure, became synonymous with man himself rather by implication than by design. The outbreak of the World War, with its urgent demands for increased production in all departments of activity, brought home to society the futility of considering the worker merely as a machine.

Industrial operations, as usually conducted, had been implicitly based on a crude mathematics. If 6 units of work could be done in one hour, then 6 x 8 would be done in 8 hours, 6 x 12 in 12 hours. The physiological necessity for sleep prevented the complete working out of this principle. Up to about 6 or 7 hours, according to the nature of the work, there seemed nothing obviously wrong with the calculation; when however, the problem was one of 12 hours, the discrepancy between the facts and the calculation challenged investigation. Though it was not then recognised, that stage marked an epoch in the history both of psychology and of industry. The focus of interest was changed from the machine to the worker of the machine, and the assistance of psychology, hitherto looked upon as a somewhat recondite study, was invoked.

The Work Curve.—Previous work of a more or less theoretical character into problems of fatigue suggested the lines of investigation. Hence the earliest work in industrial psychology was concerned with fatigue. As the time was one of urgency, the problem had to be dealt with practically, and the only measure to hand was the one which had prompted the inquiry, viz., the work curve, obtained by computing and graphing the hourly output records of numbers of workers. The reproach is sometimes made against industrial psychology that it is primarily interested in output. The truth is that output happens to be a convenient measure. Psychology's real interest lies in what is measured.

Hours of Work.—Thus the earliest systematic inquiries of industrial psychology concerned the problem of the 12-hour day in munition factories, and used as data the records of large numbers of people working over long periods. Comparisons were made between groups of people working a 12-hour day and other comparable groups working a 10-hour day.[1] In many processes the results of the latter groups showed such an increase in hourly output as more than counterbalanced the shorter time available for production, so that the total production was actually greater than when the hours of work were longer. Similarly lost time and sickness were found to diminish with the shorter working day. When hours are shortened, a long period elapses before adaptation to the new conditions is fully obtained; on the other hand, when hours are lengthened, there is sometimes an immediate reduction in hourly output.

---

[1] H. Münsterberg, *Psychology and Industrial Efficiency* (1913).

Since the War, researches along these lines have been pursued in such different occupations as: charging of blast furnaces, silk weaving, shell making, metal-polishing, tinplate manufacture and in the processes of collar machining, folding and shirt ironing in the laundry trade. The curves of the output of the average worker, when graphed, usually assume the same general shape, viz., a rise at the beginning of the spell, a period of relative stability, and a fall at the end. The interpretation of these empirical facts cannot yet be given. Slight variations occur according to the arrangement of the hours of work, but the type remains characteristic of many industrial processes. Muscio, experimenting on women medical students doing mental tests, obtained similar curves.

Rest Pauses.—An important innovation stressed by the industrial psychologist has been the introduction of short rests, in the middle of a working period, of about 10 or 15 min. duration. These regular breaks are technically known as rest pauses. It is sometimes argued that frequent irregular rests are invariably taken by the workers, either voluntarily or because the supply of work fails, and that regular rest pauses are therefore not required. Where, however, direct experiment has been possible, it has shown that the organised rest pause is the better working arrangement.

The observations of H. M. Vernon for the Health of Munition Workers' Committee proved the advantage of breaking up working spells, and since then it has been verified in the boot industry, in metal-polishing, in celluloid-polishing, in shirt ironing, in sweet-packing, in handkerchief-folding and in stamping lids. The introduction of a rest about the middle of the spell of work improves the output as a rule by about 5%, and in some processes it affects advantageously the period preceding the rest. Not only is the work improved, but the regular rest is much appreciated by the worker. The probability is that the improvement is largely due to changes in feeling; most people can face with equanimity and possibly enthusiasm the prospect of two hours' work at the end of which will come a period of free time, but to face four or five hours of unbroken labour is depressing.

The subject of rest pauses has not yet been exhaustively studied, and particular cases need particular study; still the above statements seem to be valid in general. Exactly when a rest pause should occur must depend on the nature of the work, while the amount of actual increase in output will vary with the relation of the human factor to the machine factor in the particular process.

Physical Environment.—Among other influences which have been shown similarly to affect the worker and have been effectively measured by means of the output curve are improvements in lighting, heating, ventilation and seating. (*See* FACTORY AND WORKSHOP LAW; FACTORY DESIGN; OFFICE MANAGEMENT.)

MOTION AND TIME STUDY

At an early stage the young science of industrial psychology had to encounter the previous application of quasi-scientific methods to industry, initiated in America by Taylor and Gilbreth. Their general object was to study the nature and rate of the movements made by a worker in order to eliminate the unnecessary ones. This is technically known as motion and time study. Unfortunately this study had resulted in imposing on all the so-called "one best way," obtained by analysing the mo
ments of the quickest workers. So unnatural a procedure aw
ened much criticism and no little resentment. It is not irrelev
to note that the movement originated with engineers, not w
psychologists.

Properly conducted, motion and time study are but spe
applications to industrial processes of the laws of habit formati
Young learners pick up, by watching proficients, many acti
of industry; with practice they evolve a commendable copy
uncritically they may adopt some unnecessary movemer
which, while apparently not interfering with the work, may
come fixed; the result is that the worker develops muscu
habits harmful to himself, or fails to attain a speed commensur
with his real ability. Just as the skater, swimmer or golfer
proves by expert teaching, itself the resultant of careful study,
does the industrial worker. In such varying trades as
weaving, metal-polishing, chocolate covering, it has been fou
that by systematising movements and by training novices in
relevant motions, a saving of energy results, which is an
vantage to all concerned. Faulty methods of learning are
only a hindrance during the learning period, but there is also
invariable tendency for the worker to regress to them un
certain conditions, even when they are apparently overcom

The aim of Taylor and Gilbreth, in standardising the time a
method taken to perform a task, was primarily to reduce the c
of production, and they also had in mind the welfare of
worker and higher wages. From the worker's point of vi
however, the drawback of their system was that it produce
feeling of being always keyed-up. From the psycho-physiologi
point of view it was based on the fallacy that the shortest a
speediest movements were necessarily the least tiring and th
the best style of movement could be obtained from combini
a number of best movements adopted by different workers.
the study of industrial processes in relation to the worker is
be scientific, it must consider the whole of the conditions, no
part; it must regard the worker as a human being, not as the p
former of a limited set of movements.

LEADERSHIP AND MONOTONY

Important though the material environment undoubtedly
no workers can do their best unless the general mental enviro
ment is right. Not even the very best material conditions w
result mechanically in good work, and sometimes even po
material conditions can be nullified by good mental conditio
By this is understood the conditions governing the group as
whole, dependent primarily on the efficiency or otherwise of
leadership. Industrial life is often criticised for failing to supp
that effective stimulus of working for a common end, which
more obviously evident in the army. Actually there are mo
factories where there is this sense of working for a common end
well as for individual wages, than those not familiar with t
inside working of factories are aware of.

If, as McDougall[3] asserts, "the personalities of its leade
more effectively than any other factor engender national uni
and bring it to a high pitch," it is no less true that a factory ow
its corporate unity to the personality of its leader and h
deputies. The time may come when it will be possible to test f
leadership as it now is for intelligence; at the moment the prob
lem has only been formulated. The qualities of leadership a
required by all those in charge of others, and there is no corre
tion between ability to do a job and ability to superintend othe
doing it. To the psychologist there are certain types, almo
neurotic, whose symptoms find expression chiefly in their rel
tions with others. The person who reacts always to the emotio
aroused in himself by a situation and not to the situation itsel
the inevitable "nagger" who can never govern easily becau
he is always at war with himself, the "obsessional"[4] whose ob
session can be readily touched up by the work—these represe

few whose emotional development makes life much harder
r some of their subordinates and unbearable for others. If
eir other qualities, *e.g.*, their business acumen, are so out-
anding as to justify their position, then they need as emotional
terpreter someone of different temperament to neutralise their
ore pernicious effects.

A good leader should possess vitality, sympathy, justice and
umour, as well as knowledge of the work. The emotional, and
a corollary, the physical effect on subordinates of different
ypes of leaders is patent throughout industry. Where the com-
ands of one are cheerfully obeyed, those of another arouse
uculent antagonism or sullen acquiescence. Can anyone doubt
e effect on the health, happiness and efficiency of the workers?
any authorities are unwittingly the cause of the sick leave they
eplore among subordinates.

Monotony.—In addition to the effect of the leadership, one
as to accept the fact that in modern industry, with its sub-
ivision of labour, a large number of people are employed in
peating the same limited set of movements for hours, days,
onths and years. This "repetition of movement" is often
roneously called monotony. Literally "monotonous" means
of one tone;" it suggests absence of change and refers rightly
the general mental atmosphere and not to the movements of
e worker. Repetitive movements must either be studied as
ch, in which case they belong to the psychology of habit forma-
on, or else put in their complete setting, including, at least, the
petition work, the varying amount done as the hours go on,
e opinions of fellow workers and authorities about that work,
ysiological changes, emotional changes, and the collective life
the factory. The total reaction at any given moment will be
e reaction to a composite situation which constantly changes.

The worker on one process often stigmatises some other pro-
ss as monotonous, when to the observer there is nothing to
oose between them. There are compensations too in many
ocesses if one studies the worker as a human being and not
erely as the performer of a repetition process; *e.g.*, some workers
perience a sense of power in operating a large or a delicate
achine. It is not suggested that repetition work is good in
elf; but merely to describe the repetition work as monotonous
d to imply that such description embraces the whole psycho-
gical situation, is misleading.

VOCATIONAL GUIDANCE AND SELECTION

Observation of workers shows that in particular posts some are
uch more successful both subjectively and objectively than
hers. Hence arises the question of vocational guidance, which
ust be distinguished from vocational selection, a simpler
oblem. The latter problem sets out to select a worker to fit
e job, the former to select for a given person (usually an
lolescent)that job most suited to his capacities. This theoreti-
lly presupposes a knowledge of the person, a knowledge of all
ssible occupations, and a power of relating one to the other.
hose who have done most work in this field are convinced that
e most useful measure of a person is his general intelligence.

Mental Ratio.—By suitable tests it is possible to gauge with a
gh degree of accuracy the intelligence of any child, and to ex-
ess it in a quantitative form, known as the mental ratio. This
mains fairly uniform throughout the years of growth, and
born intelligence does not develop to an appreciable extent
yond the age of puberty. It is the amount and kind of knowl-
ge and interests that separate the adult from the child, not the
telligence with which he deals with that knowledge and those
terests. To put a child of a high level of intelligence to a job
quiring little, is wasteful, while the reverse process is futile;
oreover, the one provokes discontent, the other worry.

Temperament and Character.—In other directions, viz., the meas-
ement of temperamental and character qualities, less advance
s been made. In this field, observation and interpretation are
ll the only methods available. There are some occupations
ere people of a particular temperament are more likely to
come inefficient and break down than in others.[1] This temperament is characterised by a disproportionate development of fear in some form. Whether this is due to its innate strength or to an environmental repression, or both, cannot be adjudged yet. The sufferer shows over-anxiety concerning things he cannot alter, is unduly sensitive to the opinions of authorities, etc. Sometimes the symptoms appear in a more objective form, masking their actual subjectivity, so that the focus of anxiety appears outside the sufferer, who, with more than normal frequency complains of machine trouble, unsuitable keys (in telegraphy), etc.

Such people, in the interests of themselves, their fellow-workers and the work, ought to be diverted from occupations where their mental make-up cannot fail to be expressed in the work. If they enter such occupations as telegraphy or dispensing or even coal-mining they will almost certainly break down: the breakdown will be attributed to overwork, although actually the over-work may have rather subjective than objective reality. If there is an occupational disease recognised as such, the problem is still further complicated.[2]

When the qualities of the applicant for a job have been assessed and the requirements of various trades are known, it is possible to advise a child as to what he may most advantageously take up.

Organisation.—A vast field is however still untouched. Most of the studies made so far relate to those aspects of industry which are primarily means to an end, not ends in themselves, and even in this limited sphere there is much to be done. Little is known as yet, for example, about the organiser and his organisation. It is obvious that the organisation of a big business is no mere rule-of-thumb working out of principles gained by even a scientific analysis of other places; it has some of the qualities of a work of art, and the attitude of mind of an original organiser is akin to that of the artist. No real appreciation of the field of industry is possible without a recognition of this.

INDUSTRIAL RELATIONS (*see* ARBITRATION AND CONCILIATION, 2.331).—The term "industrial relations" is used to denote the relations between all those who are engaged in industry. The history of industrial relationships up to the outbreak of the World War is a history primarily of conflict. The workpeople had only achieved something like equality of bargaining power by dint of unremitting struggle, first for the right of association, then for the recognition by the employers of their organisations as their authorised mouthpieces.

Strikes and lock-outs, when they occurred, were increasingly stubborn as the fighting resources of the trade unions multiplied, and increasingly devastating in the economic losses which they entailed to both parties as their scope became magnified. In order to prevent the outbreak of these deadly contests, the State was compelled to set up machinery for conciliation and arbitration, and statesmen were forced to pay increasing attention to industrial questions in drafting their political programmes. But in the heat of this long-drawn-out battle between the two opposing forces the essential community of purpose which should have united them was almost completely forgotten by both sides. That both derived their living from industry and that both would perish if it withered, was a thought which seldom occurred either to Capital or Labour as a whole, the one intent upon maintaining the inalienable right of the capitalist to undivided ownership and responsibility, the other on demanding some form of socialisation, a term with many and fluid meanings but generally interpreted as implying the ownership and control of industry by the State. It is true that both parties counted in their ranks men who held that a new order, substituting co-operation for conflict, was the only road to individual or national prosperity. Their voices were seldom heard, however, above the din rising from the two contending camps, each firmly entrenched in its doctrinal positions and defying assault.

Psychology*, vol. 3, pt. 3, pt. 4 (Cambridge, 1923).

The War introduced an abnormal period in the relations between employer and workman in every industrial country of importance, because all of them were belligerent. The paramount necessities of the State and the control which it exercised over the production of almost every article except those of purest luxury suspended the free play of economic forces. Though disputes and occasionally strikes occurred, usually for higher wages to meet swelling prices, they were quickly settled by government intervention instead of by the normal processes of industrial warfare. Nevertheless, the disturbance of all accepted values which the War created, the realisation of the national dependence on the industrial worker and the partial obliteration of class distinctions by the common struggle brought about a new attitude towards the whole question of industrial relations. It is not too much to say that with the Armistice industrial relations entered upon a new phase. As yet it is still in its very early stages. To suggest the lines of its ultimate development would be premature, but there are certain novel features which have emerged and which may be taken as marking a definite departure from pre-War conceptions. They may be illustrated from the experience of the three principal industrial countries, Great Britain, Germany and the United States, where under different forms and conditions similar tendencies may be traced. In contrast to them there is the Russian experiment where with the abolition of private capital the problem of industrial relations might be supposed to have been eliminated. Nevertheless the distinction between management and workers has gradually re-emerged and with it the problem once more begins to revive, as may be seen from the article RUSSIA.

I. THE WHITLEY COUNCILS IN GREAT BRITAIN

The Whitley Report.—In March 1917 a committee, presided over by Mr. J. H. Whitley, now Speaker of the House of Commons, and usually known by his name, presented its first report to the Minister of Reconstruction on the relations between employers and employed. It proposed the establishment of Joint Industrial Councils consisting of an equal number of the employers and workers in all well organised industries. Two points may at once be noticed as indicating that the authors of the report, who included several prominent employers and trade-union officials, had abandoned the view that the relation between capital and labour must necessarily be one of fundamental antagonism. In the first place, they proceeded on the assumption that trade unionism was an integral part of the industrial machinery and that any industrial reconstruction must be based on its frank recognition. Though it is true that this principle had been admitted before the War wherever collective bargaining had been firmly established, it has to be remembered that even in 1911 a national railway strike took place to secure its recognition by the companies and that in many of the lesser industries it was still far from being universally honoured.

Secondly, the committee emphasised the need for "the largest possible measure of co-operation between employers and employed." They declared that, in order to improve industrial relations, it was essential not merely to offer workpeople better conditions and a higher standard of comfort, but also "to enlist their active and continuous co-operation in the promotion of industry." The notion of co-operation was thus re-introduced into industrial history for the first time since the factory system came into existence. No doubt isolated attempts had previously been made to revive it in individual works by means of profit-sharing schemes, works committees and similar devices, but it had never been authoritatively laid down as a principle that should govern the whole field of industrial relations.

Joint Industrial Councils.—In consonance with these gene
objectives, the Whitley Committee proposed three classes
function for the Joint Industrial Councils. In the first pla
they were to provide the means for settling wages and worki
conditions. Secondly, they were to consider questions conce
ing the development of their industries as a whole, such
technical education, the initiation and utilisation of industr
research and inventions, the improvement of processes and m
chinery. Thirdly, they were to discuss certain other matt
which involved the partial association of the workpeople in t
general conduct of industry by utilising their practical kno
edge, securing to them "a greater share in and responsibil
for the determination and observance of the conditions un
which their work is carried on," "ensuring the greatest possi
security of earnings and employment," and discussing "orga
isation and appropriate questions relating to managemen
Moreover, in order to carry the spirit of co-operation from o
end of the industry to the other, it was recommended that t
councils should devolve some of their duties on district counc
and works committees.

That this was a far-reaching programme involving a n
approach to the problem of industrial relations hardly nee
emphasis. That it should not yet have been fully realised
hardly a matter for surprise, especially when the grave econom
crisis which weighed heavily upon industry after the War
borne in mind. Like other new institutions, the Joint Industr
Councils have been roundly condemned as useless, because in
few years they have failed to perform a miracle by changing t
whole industrial atmosphere. But transformations as profou
as those which the complete realisation of the Whitley schem
would mean are only accomplished slowly. They demand
long process of education both of employers and workers. Wh
is important to notice is not the shortcomings but the achiev
ments of the councils.

Seventy-three councils were brought into existence with t
active assistance of the Ministry of Labour. At the end of 19
58 were still in operation. Fifteen had fallen by the waysid
usually because they were premature on account of an insuf
cient degree of organisation in their trades. The comprehensi
report issued by the Ministry in 1923 shows that the survivo
had already accomplished a large amount of excellent work.
is true that the greater part of it was devoted to settling hou
wages and disputes, but when it is realised that many of t
industries concerned had never before possessed any machine
for these purposes, their repeated success in solving thor
questions without conflict is in itself an immense testimony
their value. Many councils, however, have gone further a
already performed work of a more constructive character.

Remarkable schemes have been set on foot in several trad
for improving education and regulating the conditions of appre
ticeship. Much has been done to improve safety and health i
collaboration with the factory inspectors and the Industri
Fatigue Research Board. At least 12 councils have gone ver
carefully into commercial questions, such as foreign compet
tion, the improving of transport facilities and the provision o
raw materials. Finally, the pottery, tramway and wire-drawin
councils have set an important example by investigating th
costs, wages and finances of their industries. It is only by exam
ining the detail of the work done that the progress which it rep
resents and the influence which it has had on the relations be
tween the employers and the workpeople concerned can be fairl
estimated. Enough has been said, however, to justify the opinio
that the Whitley scheme is operating steadily and beneficiall

Methods in the Five Great Industries.—One of the princip
criticisms levelled against the scheme is that it has not bee
thought fit for adoption by the largest industries—mines, cotto
engineering, iron and steel and shipbuilding. In these industrie
machinery for bargaining and for dealing with disputes ha
long been in existence, which they did not wish to alter int
conformity with the Whitley model. It may, however, be note
in passing that, except in the iron and steel industry, seriou
stoppages have occurred in all the others since the Armistice

nay yet be found that some machinery for co-operation on a ader basis than now exists is necessary to ensure peace and sperity in these industries.

inally, special mention must be made of the important innoon made in the relations between the railwaymen and the ipanies by the Railway Act of 1921. It was originally proed to provide for the inclusion of two Labour representatives the Board of Management, but this suggestion was dropped avour of a scheme setting up a Central and a National Board deal with wage claims and disputes, and Railway Joint Counon each of the four great lines to deal with the local applicaof national agreements, suggestions as to operating, working kindred subjects, and other matters of mutual interest such ‘co-operation with a view to securing increased business, ater efficiency and economy.” Under these councils are secal councils, while in every station or dépôt where 75 men are loyed a local departmental committee is established, whose eral objects are to provide contact between management and loyees and to increase the latter’s interest in their work by ng them an opportunity of discussing matters affecting not their own conditions but also the efficiency and organisaof the working of the railway. In other words, the Whitley iciple has been adapted to the railways and has certainly tributed to their smoother working.

onclusions.—This brief survey will have made it clear that Great Britain a distinct change is observable in industrial tions since the War. A rival notion to that of the diametrical osition between capital and labour has been introduced in shape of co-operation for the common benefit of both. This involved not only the unqualified recognition of the trade ons as part of the machinery of industry, but also the admisof the right of the workman to some participation in its cy and responsibilities. Lastly, except in the case of the es and the railways, the demand for the direct nationalisaof industry is perhaps less confident than it was before the eriences of the War and the Russian Revolution, but the of syndicatising industries still on commercial lines with e supervision has acquired a good deal of prominence.

I. THE GERMAN SYSTEM OF WORKS COUNCILS

he development of German industrial relations since the istice has taken place in a very different setting. Whereas reat Britain the War produced a disturbing interlude which the general organisation of society unchanged in its outward is, if modified in its spirit, in Germany the close of hostilities ight about a radical transformation. The German Revolunot merely substituted a republic for a monarchy, but it red the whole social equilibrium. For the first years of the Germany the Social Democratic party was the dynamic e in the Government, and it was during that period that the stitution of Weimar was framed. That remarkable docut introduced profound changes in the sphere of industrial tions as in other spheres of German life. After laying down principle that the “labour force” (*Arbeitskraft*) falls under special protection of the Federal Govt. and enumerating ous measures to ensure that protection, the constitution vided in Article 165 for the establishment of two institutions ch are beginning to play an important part in German indusl life—the Federal Economic Council (*Reichswirtschaftsrat*) the works councils (*Betriebsräte*).

peration of the System.—Works councils (*q.v.*) have not been ed during a normal period, and it is still premature to pronce any definite opinion on their value and possibilities. It nevertheless be stated with considerable confidence that works councils have established themselves as a permanent ure of the German industrial system, whatever modifications may be destined to undergo. To say this does not mean the employers are fully reconciled to them or that the kers are fully conscious of their possibilities. The former show the greatest reluctance to admit the councils to any participation in the problems of production. They have uently placed obstacles in their way and have generally tried to restrict their functions to that of intermediaries between workers and management. As a result, the number of cases in which works councils can be stated to have had a beneficial effect on production is small, though on the other hand the employers’ fears that they would have a subversive and pernicious influence have not been realised, save where the Communist element has succeeded in gaining control. The workers, on their side, have often not proved themselves capable as yet of using the new machinery effectively. Their lack of technical knowledge has hampered them, while in smaller works a considerable amount of indifference is still to be found. At the same time, they have established their right to receive important information, which the trade-union leaders regard as a means of gradually educating Works Councillors in their duties.

On the social side the results of the works councils have been more pronounced. They have played a considerable part in the enforcement of the eight-hour day by exercising a supervision on behalf of the trade unions, which has prevented abuses and secured closer observance of the collective agreements. But perhaps the most remarkable results achieved by the councils from the workers’ standpoint have been in connection with dismissals. By investigating innumerable cases in which improper grounds of discharge have been alleged and by taking them before the conciliation boards, the works councils have gradually built up a jurisprudence which affords a real guarantee to the worker against arbitrary action on the part of his employer. If the councils had attained no other results, their action in this field alone would have justified their creation from the workers’ point of view. On the whole, it may be said that, although their value and effectiveness vary greatly in accordance with the spirit which both sides have brought to bear on them, the works councils have justified themselves and are likely to acquire further authority as time goes on.

III. THE GERMAN FEDERAL ECONOMIC COUNCIL

Functions of the Council.—Any estimate of the influence of the Federal Economic Council on German industrial relations is subject to the same qualifications as in the case of the works councils. As an institution it is still in its infancy; in fact, its form is still provisional and remains to be finally determined by a bill under consideration in 1926. Hitherto it has consisted of 326 members, but experience has shown this number to be too large and the bill reduces it to 126, of whom 41 are to be nominated by the employers’ organisations, covering industry, agriculture, commerce, banking and transport, 41 by the trade unions of various kinds, 14 are to represent private corporations such as the municipalities, co-operative associations and insurance companies, and 30 are to be appointed by the Federal Govt., including two representatives of the Press. The functions to be allotted to this permanent council are analogous to those which the provisional council has been exercising during the past six years. In the first place, all government bills of an economic or social character have to be submitted to it for advice and its views must be presented to the Reichstag, whether favourable to the Government’s proposals or not. The council may also depute members to explain its conclusions while the bill is under discussion in Parliament. The council has a further power of considerable importance, namely, that of conducting “inquiries into questions of fact, in the economic and social field” (*Untersuchung tatsächlicher Verhältnisse auf wirtschafts- und sozial-politischem Gebiet*), and for this purpose the council is to be armed with compulsory power to obtain information and to hear evidence on oath.

Similar Institutions in other Countries.—It will be seen that the Federal Economic Council is not merely or even primarily concerned with industrial relations, but that it is called upon to advise upon all economic questions and to exercise functions of a semi-political character. In fact, it represents the modern tendency, which may be found in the formation of a *Conseil National Économique* in France and in the new Fascist *Consiglio Superiore dell’ Economia Nazionale* in Italy, to submit economic questions to the consideration of expert professional bodies instead of leaving them to be exclusively decided in the light of the political circumstances of the moment, which exert so large an influence on the deliberations of Parliaments and often produce results that are hardly consonant with the best interests of the country. From the point of view of industrial relations, however, such bodies are of considerable significance, as they mark once again the post-War tendency to admit representatives of the workers to direct consultation on the wider problems of industry, instead of leaving them as hitherto to be dealt with only by governments and employers. Enough has been said of the new bodies which the German Constitution has called into being to show that in Germany, as in Great Britain, this tendency has won a large measure of recognition and the status of the worker is undergoing a gradual development in the direction of participation in the responsibilities of management.

IV. TENDENCIES IN THE UNITED STATES

To turn from Europe to the United States is to discover industrial relations based on quite other conditions and determined by circumstances which find no parallel in the Old World. The industrial evolution of a new country with vast natural resources and incalculable possibilities of expansion must necessarily differ widely from that of small, highly developed areas such as Great Britain and Germany. The United States was a predominantly agricultural country until very recent times, and the phenomenal growth of its industry in the last two generations has not even yet been so great as to make it predominantly industrial rather than agricultural. There is still a far greater measure of fluidity in American than in European life. The workman of to-day may still be an employer to-morrow and a millionaire before he dies. A man who fails in the town can still return to the country, or who fails in one job can pass to another with the certainty of finding employment. In a word, the towering occupational and class barriers which hem in the European worker's progress through life only exist as yet in a very minor degree in the United States. The consequence has been a different attitude towards the whole subject of industrial relations. The outlook both of employers and workers remains essentially individualistic. While until recently the former has been uncompromising in the maintenance of his undivided sovereignty in his own plant, the latter have shown little interest in the orthodox doctrine of class warfare, only a moderate inclination to trade unionism and a positive repugnance to many forms of State interference. The late Mr. Samuel Gompers throughout his career fought vehemently against any endorsement of State schemes of insurance by the American Federation of Labor, and demands for industrial legislation which have been pressed for years by the trade unionists of Europe have been vigorously opposed by the trade unionists of America.

Besides this individualistic tradition, which is characteristically American, there is another factor which has directed industrial relations into unfamiliar channels. The ordinary growth of the population was quite insufficient to supply the vast demand for labour created by the rapid expansion of American industry. The result was a tremendous acceleration of the stream of immigration from about 1890 onwards, until in the years preceding the War it had attained an annual figure of over a million. A large proportion of these new American labourers were drawn from southern and eastern Europe, instead of from the northern countries which had previously furnished the main body of immigrants. They had little or no industrial experience, they were usually ignorant of the meaning of trade unionism, and even if they attempted to combine for trade purposes, they were unable to comprehend the speech either of their own officials or of their fellow members. As a result, the employers enjoyed a power in the United States which their European colleagues had long since forgotten. Trade unionism was weak and extremely difficult to promote in the face of the natural obstacles already mentioned, reinforced by the relentless and uncompromising hostility of the employers. Nevertheless, in certain industries, notably the garment trade, one of the worst paid and most difficult to organise, it made astonishing progress, and even in other industries such as the steel industry, coal districts like West Virginia, where organisation was un to obtain a solid foothold, the workers began to band toget for fighting purposes, often under the aegis of the loose- extremist body known as the "Industrial Workers of World."

Industrial Warfare.—Under these conditions industrial fare was carried on by both sides with a violence and ruthl ness never approached in Europe. In the face of the enorm power of American capitalism, which was often unsparingly to crush any incipient combination for protecting their inter the workers were driven by a feeling of desperation not me to resistance but to open revolt. Strikes were not just tes endurance and organisation, but not infrequently produ armed conflict and considerable bloodshed. In the decade ceding the War and during the War itself industrial relati in America were apparently growing steadily worse, and it generally concluded by European observers that their devel ment was following the normal course already familiar in Eur that as the abyss between capital and labour widened, orga sation would grow stronger on either side until each was fectly entrenched against the other. Despite certain pecu features, there was no essential difference in the problem presented itself in the new world. America was a generat behind Europe in its trade unionism, but was pass through the same recognisable stages and would arrive at essentially similar conclusion. The damming of the immigrat river first by the War and then by "quota" legislation wo only hasten the process by solidifying the working masses in United States and removing one of the principal obstacles to growth of trade-union organisation.

American Proposals.—Though it would perhaps be rash assert that this view has already been falsified by experie events seem to point to a different evolution. Since the Ar stice there has been more discussion of industrial relations in United States than perhaps in any other country. The Americ public seems to have awakened to its immense importance the whole future of the country. When President Wilson cal his industrial conference in 1919 to elaborate proposals for bet relations, it aroused far more interest among the general pub than did a similar conference convened by Mr. Lloyd George England in the same year. Although it reached no very positi conclusions, it probably served its purpose by acquainting American people with the elements of the industrial proble

Since that time their education has been steadily continued the Press of all grades. The output of books, magazine newspaper articles on the subject has been immense. Big e ployers like Henry Ford, J. D. Rockefeller and Edward Fil distinguished men of learning such as President Eliot of H vard, politicians, journalists, church congresses and numero private bodies have contributed actively to the discussion, wh a great deal of industrial investigation has been done both individual research workers and by institutions such as Russell Sage Foundation. The result has been to create atmosphere more favourable to the peaceful improvement industrial relations than exists in any European country. Wit out by any means pretending that the old prejudices or anta nisms as between capital and labour have been eliminated, may be said that they have been already softened by the f play and approval given to liberal and progressive ideas, a restrained by the feeling of responsibility which the nation interest displayed has engendered.

What, then, are the tendencies which are beginning to sho themselves as the result of all this American discussion? In th first place, there is a marked insistence on the application democratic principles to industry. America is a country whi prides itself above all on its democracy, and once the questio is stated Americans find it as difficult to approve autocrat methods in industry as they do in politics. Moreover, they a beginning to believe that in a democratic country comple industrial autocracy is not really possible, or that, in Mr. File words, "industrial democracy is inevitable, because politic er has been given to the masses." In fact, the widespread rest evoked in the problem of industrial relations in the ed States is largely due to the belief that unless it can be ed by industrial methods within industry, it will become a ical problem to be solved by political methods outside stry. For many Americans, then, the solution of the indus- problem appears fundamental to the maintenance of democ- . The general view now gaining ground among them may ummed up in a dictum of the Bureau of Industrial Research. ne of the great tests of democracy in the years to come will he ability of American employers and wage-workers to find sis of democratic co-operation in the government of indus- Unless industry can be constitutionalised on a democratic s, there is serious danger of class conflict culminating in e form of revolution."

xperiments in Certain Industries.—In order to "democra- " industry numberless "plans" are now on trial. In the nent trade a regular system of co-operation has been estab- d by the employers and the Amalgamated Clothing Workers merica, starting with Messrs. Hart, Schaffner and Marx, of the largest firms in Chicago, and thence spreading through industry. On the railways an interesting experiment has initiated on the Baltimore and Ohio Railroad which has e been adopted by other great American lines and by the adian National Railway. Joint committees have been set rather similar to those which exist on the British railways, main objects of which are the promotion of efficiency, the ination of waste and the stabilisation of employment. All available evidence testifies to their success, both from the loyers' and the workers' standpoint. A large number of perative schemes may be found in other industries, varying ely in type but all based on the idea of securing the whole- ted collaboration of the workpeople by enlisting their direct rest in the running of the establishment.

n some cases constitutions have been set up on the American el with a Senate and a House of Representatives, in others profit-sharing element is introduced in some shape or form. no means all of these schemes have been instituted in agree- t with the trade unions; in fact, it would probably be true ay that the majority were promoted by the employer with object of preserving the "open shop" and keeping unionism But whatever their origins, these works committees have oubtedly done much to improve industrial relations. The istics published by the National Industrial Conference rd, an important employers' organisation, show that in 1924 e were 814 establishments possessing works committees re 1,177,000 workpeople were employed, as against 225 loying 391,000 in 1919. When compared with the whole of erican industry, this does not represent a very large propor- and as in the case of some of the British Whitley Councils, e works councils have failed to survive in the United States. maintain, therefore, that the "democratic" movement in istry is universal or overwhelming would be misleading. re is still a large section of employers who remain wedded to fashioned methods and who are opposed even to collective gaining. There is no doubt, however, that the new method is ing steady progress, and what is perhaps most significant he changing attitude of labour towards it.

ages and Production.—As has already been pointed out, the vidualist tendency and the vast influx of immigrants have dered trade-union organisation far more difficult in America n in Europe. In addition, the American working man is e intent on earning good wages than on any other objective. standard of living is considerably higher than that of any opean worker and his principal aim is to elevate it still her. He is therefore disposed to assist in increasing produc- , if by doing so he is assured of increasing his own income. has no objection to adopting "capitalistic" methods, to ing bonds or to taking shares in the enterprise which employs , if he sees in them the means of augmenting his material perity. As a result of this attitude one finds that the situa- in the United States differs from that in Europe.

In the first place, there has been a great increase of output per head since the War, due to the improvement of machinery and the more economical use of the forces of production, while on the workers' side there has been a reduction of hours and a rise in real wages. The American workman, so far from offering resistance to mechanical progress, has frequently promoted it, and some trade unions even employ their own experts on scientific management, to which until recently they were violently opposed.

Secondly, the purchase of stocks by employees has developed in a remarkable way. One American economist calculates that, whereas shareholders with an income between $1,000 and $5,000 only received $38,000,000 or 1·8% of the total dividends reported in 1916, they received in 1921 no less than $562,000,000 or 22·7%. To illustrate this point, it may be mentioned that out of the 60,000 employees of Armour & Co. 40,000 are stockholders. In the Philadelphia Rapid Transit Co, 11,000 employees held over $10,000,000 worth of stock in 1925, more than double the value of their holdings in the previous year. Similar instances could be multiplied to show that the American worker is becoming a holder of capital.

Workers' Investments.—Thirdly, labour has initiated its own banking movement. The first labour bank was founded at Washington in 1920; at the end of 1924 there were 33 already in existence, with resources estimated at about $150,000,000. The leading part in this movement was taken by the Brotherhood of Locomotive Engineers, one of the strongest American trade unions, under the leadership of Mr. Warren S. Stone. Their objects, as he states them, are simply to offer the working man safe custody for his money and sound advice for its investment. But it is calculated that the American workers are in a position to save from $6,000,000,000 to $7,000,000,000 annually, and Mr. Stone asserted that "if they would save and carefully invest their savings, in 10 years they could be one of the dominating financial powers of the world." This suggests possibilities in labour banking which are at least still far from being realised. The experiment is yet in its childhood, but whatever its final form it must exert a considerable influence on the psychological attitude of American labour towards capitalist enterprise.

Co-operation Rather than Warfare.—Mr. Stone defined three phases in the trade-union movement. The first two—organisation and the struggle for collective bargaining—are familiar in all industrial countries. "The third cycle or phase," he says, "lies in constructive development towards a system of co-operation rather than war; and the most striking evidence of this phase is the labour bank." Though we have seen some evidence of a similar tendency in Great Britain and Germany, it is only in America that the labour movement seems to be consciously and openly adopting a co-operative policy. In doing so they are not abandoning the goal of securing an even larger share in the control of industry, but their method of approach is entirely different. Instead of preaching the destruction of capitalism, they are aiming at its peaceful penetration. Prof. Carver, of Harvard, goes so far as to claim that "the only economic revolution now under way is going on in the United States. It is a revolution that is to wipe out the distinction between labourers and capitalists by making labourers their own capitalists."

This is probably an overstatement of the case, but it is certain that the policy of co-operation with capital and of intensifying production is looked upon with favour by the American Federation of Labor. The last report of their Executive Council, after defining collective bargaining as the first function of trade unionism, states that "there is a still more important function that the union can render—that of participating in finding better methods of production and greater production economies." It recommends that the Baltimore and Ohio scheme of union-management co-operation should be closely studied and the advice of experts on shop management systematically sought. The Executives even recommend that their members should take part in works committees in establishments where the trade union is not recognised, on the ground that they promote solidarity among the workers and may thus assist trade union organisation. Mutual confidence between employer and employed are essential in order that the latter may be assured a fair return for the increased efficiency which he helps to secure, but on this condition co-operation to promote industrial prosperity is put forward as the policy to which organised labour should give a fair trial.

It would be hazardous to conclude, however, that industrial relationships in America are definitely set in the path of conciliation and co-operation. The phenomena which have just been briefly reviewed are not universal in character and have occurred during a period of overwhelming prosperity. How far they may be its cause or its consequence is an undecided question. Some observers think that the enthusiasm of labour for high production would be killed by a period of trade depression; others that it depends for its maintenance upon the uninterrupted progress of mechanical invention, which by multiplying production without increasing prices has given the American worker a steadily rising standard of living. All that can be safely said at the moment is that the United States is experimenting boldly with a new relationship between employer and worker and that the success already achieved is sufficient to make its further development a matter of obvious interest and importance.

V. CONCLUSION

This bird's-eye view of the development of industrial relations seems to suggest that they are now entering a critical, perhaps a decisive, phase of their history. Just as the end of the War ushered in a new era in international politics, so it may be destined to mark a new point of departure in the politics of industry. It is certain that, like all other human institutions, they cannot remain stationary. Either they must develop further on the lines of conflict rendered constantly more menacing to the community, as the strength and resources of the organisations of both sides increase and become growingly capable of exerting pressure on its vital organs, or alternatively conflict must give place to co-operation based on the recognition of the essential partnership of labour and capital and on their common interest to stimulate production, if they are to survive in an age of aggravated competition. Whereas before the War the signs of this latter tendency were barely discernible, clear evidence of its growth has been shown to exist to-day in Great Britain, Germany and the United States. A similar movement may be found in other industrial countries such as Czechoslovakia, Austria and Norway, where compulsory works councils are in operation, or in France, where there are voluntary councils in many factories. But it is much too soon to suggest which of the two tendencies will prevail. The decision between them will only be slowly worked out over the coming decades. The ultimate answer will determine for good or for evil the future course of our industrial civilization.

INDUSTRIAL RESEARCH: *see* RESEARCH, INDUSTRIAL.

INDUSTRIAL SCHOOLS.—In Great Britain children may be sent to industrial schools on such charges as found begging, found wandering and not having any home, found destitute and hav
parents undergoing imprisonment, found in the care of a pa
or guardian of criminal or drunken habits, frequenting the c
pany of a reputed thief, residing in a disorderly house and
more serious offences, such as theft, larceny, housebreaking.

Industrial schools tend to approximate more and more clo
to the ideal of residential elementary schools, situated in plea
surroundings in rural districts, for the attendance of chil
suffering from parental neglect, or subjected to an environm
likely to cause delinquency or criminal habits. The schools
inspected by the Home Office and the Board of Education,
as far as possible "institutional" life is eliminated. As m
freedom is allowed as is consistent with the maintenance of o
and good conduct, and the clothing supplied is similar to
worn by ordinary school children.

School Routine.—School routine, as a rule, consists of gen
educational work and vocational training in equal proporti
Sports and games are encouraged. The trades and occupat
taught to boys are tailoring, shoemaking, carpentry, farm
gardening and instrumental music; a few of the institutions
training ships. Girls are trained in all branches of dome
work. The after-careers of the great majority of industrial sc
children are satisfactory, and many of the children obtain lu
tive and congenial employment. With the decline in truan
truant schools have been discontinued, and truants are usu
committed, in London and elsewhere, to industrial schools u
they reach the age of 16.

Boarding-out.—Many education authorities have adop
schemes providing that children under eight years of age
are committed to industrial schools shall, whenever conditi
are suitable, be boarded-out with foster parents. By this
rangement the children receive the advantages of home life,
erally in rural surroundings, and can attend the local element
schools. In 1925 nearly 300 London children were boarded-
with foster parents. Cordial and often enduring relations
formed between the children and their foster parents.

Statistics.—The number of persons dealt with in juve
courts has decreased during recent years. In 1913, proceedi
were taken against 37,520 children. During the War the num
reached the high-water mark of 51,323 in 1917. There has si
been a gradual decrease; in 1924 the number was 29,624.
majority of the "1924" children were dealt with as follows

Fined	9,190	Bound over	2,41
Dismissed	6,560	Ordered to be whipped	60
Placed on probation	5,812	Sent to reformatories	52
Charge withdrawn	3,779	Sent to industrial schools	52

The decrease in the number of charges may be attribute
improved social conditions, increased and more efficient organ
tion of children's care work, and the development of the
tional system of elementary education. There has also bee
large decrease in the number of committals to industrial or
formatory schools in proportion to the number of child
charged, largely due to the greater use now made by the co
of the powers conferred by the Probation of Offenders Act, 19
Magistrates hesitate to remove a child from its home un
they are satisfied beyond doubt that such a course is in
best interest of the child. (*See* CHILD LABOUR AND WELFARE.
(G.H.GA.

INDUSTRIAL WELFARE AND MEDICINE.—Human bei
possess intelligence, and their health depends on psycholog
as well as on physiological environment. Mental and phys
activity are necessary to health. From the industrial poin
view both require to be maintained in order to ensure efficien
which spells for an employer a contented personnel and for
employed physical health and a "worth while" life. Appre
tion of this point of view has in recent years been expres
through different activities aimed at maintaining mental c
tentment and physical health, at preventing sickness and mor
ity, and at restoring the sick to health; these lines of activity
not mutually exclusive. They may for convenience be conside
under the headings of Industrial Welfare, Industrial Fatigue a
Industrial Medicine.

I. INDUSTRIAL WELFARE

This entails not merely compliance with statutory require- nents as to the provision of specified accommodation, but the ask of getting each worker to take an intelligent interest in his wn health and efficiency, in that of his fellows and in that of the stablishment to which he belongs. The movement, which was nly embryonic before the World War, received great impetus in ;reat Britain from the recommendation of the Health of Muni- ion Workers' Committee that welfare work should be adopted or munition workers, and from the series of memoranda the ommittee issued explaining how the work should proceed.

Progress in Wartime.—A department was created in the Iinistry of Munitions to develop the scheme which at first was articularly pursued for women, girls and boys. Welfare super- isors were appointed to supervise (*a*) needs within the factory, nd (*b*) needs outside the factory. The work within the factory overed the selection of workers for engagement; supervision of eneral behaviour; of progress and apprenticeship; of transfer nd disposal of workers; of general cleanliness, ventilation and emperature; of canteens; of ambulance, rest-rooms and first- id; of cloak-rooms and sanitary conveniences and of overalls.)utside the factory it covered housing accommodation, transit acilities, sick visiting, recreation and education. The keeping nd studying of personal records of earnings, sickness and acci- ents was organised. Welfare committees composed of workers ere found invaluable to the activities of the superintendents. 'he scheme was first developed for national factories, but the timulus to private firms of financial assistance from excess rofits duty helped greatly to wider extension of the policy.

While activity on these lines, which came to an abrupt termi- ation on the cessation of hostilities, was still in progress, the Iome Office, in 1916, consolidated much of the ground won by btaining powers under the Police, Factories, etc. (Miscellane- us Provisions) Act, 1916, enabling the Secretary of State by rder to require occupiers of factories to make reasonable pro- isions relating to "arrangements for preparing or heating and aking meals; the supply of drinking water; the supply of pro- ctive clothing; ambulance and first-aid arrangements; the upply and use of seats in workrooms; facilities for washing; ccommodation for clothing; arrangements for supervision of orkers." Under these powers 14 orders have already been made oncerned with the special needs of different industries. At the ame time a series of valuable pamphlets have been issued to set rth how the requirements of the orders can be complied with. ction on these lines continues; but already some matters have ecome of general application, thus drinking water must now be upplied in all factories, while the provision of first-aid has be- me generally compulsory under the Workmen's Compensation ct, 1923.

Extension of Voluntary Welfare.—Meanwhile activities which ay be called "voluntary" welfare have extended, notwith- anding the tendency during trade depression to hold back from ew ventures. At least 1,000 firms to-day have welfare workers, compared with about 30 in 1913. Housing efforts, recreation rounds, institutes, educational schemes, nurses and sick visiting, nteens and dental clinics at factories, all provide examples of tension of factory welfare without legal compulsion. In these ays modern industry is recognising that well-directed welfare an economic proposition and makes for contentment.

The Mining Industry.—Reference has so far been confined to e welfare movement in reference to factory employment; but tion has not been confined entirely to this field. In England in 72 the Metalliferous Mines Regulation Act called for the ovision of accommodation for enabling persons employed in etalliferous mines to dry conveniently and change their clothes. 1910 the Mines Accidents (Rescue and Aid) Act gave power make orders relating to: (*a*) The supply and maintenance of ap- iances for use in rescue work, and the formation and training of scue brigades; (*b*) The supply and maintenance of ambulance pliances and the training of men in ambulance work.

The Coal Mines Act of 1911 contained, too, an important ause providing for accommodation and facilities for taking baths and drying clothes where the majority of workmen employed in a mine desire such. Unfortunately this clause was a dead letter except at some half-dozen collieries. But under the Mining Industry Act, 1920, welfare work for miners received a great impetus. This Act provides a fund, derived from a levy of 1d. a ton on the output of each mine every year, to be applied for purposes connected with social well-being, recreation and conditions of living of workers, and with mining education and research, and with such purposes as the Board of Trade may approve; but the provision of dwellings is expressly excluded from such purposes.

The fund amounts to about £1,000,000 a year; its allocation is directed by an independent central committee on which both miners and colliery owners are represented. Four-fifths of the contributions coming from each coal-field must be spent within that field: the remaining one-fifth of the fund is devoted to welfare matters of mutual interest to the whole industry, such as the promotion of research into safety and health, and the provision of higher education for miners and their families, to each of which purposes the central committee has set aside approximately £500,000 out of the first five years' contributions to the fund. Expenditure from the fund is now year by year keeping pace with contributions. The Act of 1920 was due to expire in 1925, but the success achieved by the activities thus instigated has led to prolongation of the life of the levy to the fund for a further five years.

The total credits of the fund on Dec. 31 1925 amounted to £4,740,339; and apart from the £100,000 already mentioned, allocations had been made for district purposes as follows:—

Description	Total Number of Schemes	Total Number of Allocations	Money Allocated
Recreation (chiefly recreation ground and institutes) . .	844	1.455	2,027,564
Health (convalescent homes, pithead baths, ambulance and nursing services, etc.) . .	126	198	958,771
Junior education . . .	18	25	26,362
Expenses of district committees	. .	96	25,464
Total	988	1,774	3,038,161

The research is directed by a safety-in-mines research board, acting in collaboration with a health advisory committee; higher education is effected by assistance given to local education authorities and universities.

The central committee consults with district committees concerning the amount and purposes of grants in each district. Interest attaches to the items shown on the table just given. They display the activities of the fund as progressing (with the one exception of a few allocations for pithead baths) on needs *outside* working hours; while progress in factory welfare made under statutory orders is extending with regard to needs *within* working hours. The contrast is sharp.

A Comparison.—In the case of factories voluntary effort is forwarding outside welfare schemes; but in the mines no similar efforts are taking place with regard to such needed inside welfare as the provision of drinking water, improved lighting, pithead baths or kitchens.

The procedure followed in these two lines of advance is also in contrast. Factory welfare proceeds through statutory orders, compliance with which can be enforced; while mining welfare consists of activities, originated and pursued by the mining community, but financed through a statutory levy. Thus the activities pursued for munition workers have been diverted into two separate streams. Still all welfare activities, in addition to their wide social aspect, undoubtedly exert a powerful influence in promoting industrial health.

II. INDUSTRIAL FATIGUE

The maintenance of health in industry, especially with regard to women and young persons, has always been a driving force in our code of legislation controlling factories and mines, but its close study is practically a new science, known technically as the study of industrial fatigue. In Great Britain the study is to-day pursued on general principles by the Industrial Fatigue Research Board, an integral part of the Medical Research Council. This board came into existence in 1918, owing to appreciation of a national need for intensive investigation to which attention was directed during the War by the activities of the Health of Munition Workers' Committee. Problems of interest to particular establishments are tackled by the National Institute of Industrial Psychology (*see* Industrial Psychology). Much practical knowledge as to human activity, embodied in over 30 reports issued by the board, and in the Journal of the Institute, has been placed on a scientific basis.

Certain points may be succinctly stated: work is necessary to health, and health is needed for efficient work; even steady work is better than spasmodic efforts; an optimum temperature, which should vary about a mean, exists for each process and is associated with best output, least sickness and fewest accidents; ventilation is to be read in the stimulating effect of air movement, rather than in change of air; rest periods during long spells of work, particularly if posture is changed, may increase output and lessen monotony; monotony in repetitive work, in temperature, in ventilation, in long spells of activity without pauses, and even in food supply, is disadvantageous; good factory canteens improve health and output; change of personnel, *i.e.*, labour turnover, reduces production and increases lost time due to sickness and accident; suitable overalls create pride in work and in person; vocational training adds joy to work; vocational selection on engagement increases output and reduces labour turnover; certain workers exhibit a predisposition to sustain accidents and should be employed only where accident-risk is at a minimum; the tendency to sustain accidents is associated with a tendency to fall sick.

The introduction into industrial organisation of such knowledge promises rapidly to revolutionise industrial management, and to prove the health-value to the community of well-conducted occupations. More knowledge as to the laws of human activity remains to be acquired; but by adopting what is already known, industry will prove to be our most powerful influence for maintaining public health.

III. INDUSTRIAL MEDICINE

Industrial medicine is concerned with the prevention of sickness and the restoration to health of the disabled. Prevention calls first for determination of causes, and is based on information gathered from various sources. Thus, the occurrence of industrial accidents must be notified by employers to inspectors of factories and of mines. Modern research into data so collected has enabled important protective measures to be adopted, and has also established the tremendous importance of personal, as contrasted with mechanical, factors; they account for 80% of industrial accidents. Further, just as in the case of sickness, the newly employed and those who are not-quite-well are disposed to sustain accidents, while some workers exhibit a definite predisposition to get hurt. Action should, therefore, aim at interesting workers in accident prevention through the safety-first movement (*see* Safety First), at reducing labour turnover, at maintaining health, and at eliminating the susceptible. Under the heading of accidents are here included sudden gassings, *e.g.*, from carbon monoxide, nitrous fumes and arseniuretted hydrogen, as well as caisson disease.

Occupational Diseases.—Information as to the occurrence of certain occupational diseases, *e.g.*, anthrax, toxic jaundice, chrome and epitheliomatous ulcerations, and poisoning from lead, mercury and arsenic, is obtained from notification sent by practitioners to the chief inspector of factories. Lead poisoning is the leading instance; it has been used, on account of its specific effect upon women, as a stalking horse for legislative advance against industrial poisons; its causation, displayed by study of notified cases, has now been narrowed down to inhalation of dust and fumes containing lead. Measures adopted to prevent the
generation of dust or to keep it under control, have proved
successful that lead poisoning in factory industries has l
most of its terrors; only where measures have not been, or ca
not be, adopted, as in the house-painting industry, is it stil
serious occupational menace; but constant alertness is need
to perfect the protection of those employed as new processes co
into vogue, *e. g.*, the use of the oxyacetylene flame to cut throu
steel plates coated with lead paint when breaking up old shi

Compensation claims for diseases named in the Schedule
the Workmen's Compensation Act, 1906, give information co
cerning the occurrence of other diseases, of which certain tro
bles which particularly concern coal-miners are the most i
portant, *i.e.*, nystagmus, and miners' beat knee, beat hand a
beat elbow. Here recent investigation into causation is ahe
of prevention; thus, the distressing trouble, nystagmus, of whi
the manifest symptom is involuntary oscillation of the eyeba
is associated with work for long periods in imperfectly light
galleries of coal-mines; the worse the illumination, the great
the prevalence of the disease. Owing, however, to the dang
of explosions from mine-gases, the problem of improving t
lighting underground is not a simple one (*see* Coal; Mining).

Cataract.—In contrast stands another compensatible e
trouble, cataract, which occurs among glass blowers and fu
nacemen exposed to glowing heat. Here means for preventi
are known; they consist in wearing spectacles, the glass of whi
has been specially devised for cutting off heat rays· but di
culty arises in getting the workers to use them.

Phthisis.—Further knowledge is drawn from occupatio
mortality records. They reveal any undue prevalence among
group or groups of workers of some particular cause of deat
phthisis is the most notable example (*see* Tuberculosis). R
cent statistical investigation has shown that when this cau
of death (*a*) is the only one in excess, its undue prevalence
due to the spread of infection among persons whose daily wo
brings them close together, *e.g.*, in tailoring, printing and maki
boots and shoes; (*b*) is associated with excessive death-rat
from other lung diseases, and occurs later in life than usual,
happens among sandstone masons, gold-miners, tin-mine
grinders of metal, some pottery workers and others; its excessi
prevalence is due to inhaling fine dust of silica, which sets u
condition in the lungs known as silicosis, a condition which tak
some years to develop and predisposes its victims to tuberculo
infection; and (*c*) is associated with excessive death-rates fr
all other causes of death, and occurs rather earlier in life th
usual, as occurs among publicans and inn-servants, its und
prevalence is caused by excessive indulgence in alcohol.

Knowledge of causation in each case points the way to p
vention: (*a*) Commodious, well ventilated and lighted premis
associated with medical examination to eliminate the tuberc
lous, will rid tailoring, printing and shoe-making from the scour
of phthisis. (*b*) Reduction to a minimum of risk from breathi
silica dust must abolish silicosis; the problem now belongs
the technical engineer and is being solved in certain industri
Compensation is granted for silicosis on the South African g
mines, on the Broken Hill mines of Australia, in Ottawa, Cana
and in Great Britain in the refractories industry under the pow
of the Workmen's Compensation (Silicosis) Act, 1918, which m
be extended to other industries. The financial burden of co
pensation is promoting active attention to dust prevention a
control. (*c*) Limitation of alcohol consumption, such as has be
taking place in this country in recent years, and could be exte
ed, has already reacted not only upon the occurrence of phthi
in industry, but also of ill health from other causes, includi
accidents.

Cancer.—Another disease to which mortality records ha
directed attention is occupational cancer (*see* Cancer). Work
who handle pitch, a distillation product of gas-tar, and othe
who mix pitch with coal-dust in the manufacture of briquett
suffer from warts which appear on the exposed parts of t
skin, and also on the scrotum. These warts show a special ten
ency to become epitheliomatous with the formation of " pitc
cancer. Shale-oil workers coming in contact with crude paraf

product obtained by distillation, similarly suffer from warts
d "paraffin" cancer; but workers manipulating refined paraf-
do not suffer. Chimney-sweeps have long been noted for
eir high death-rate from scrotal cancer which originates from
posure to soot, a distillation product of coal. Quite recently
equally high mortality from scrotal cancer has been revealed
nong mule-spinners in the cotton trade due to contact with
bricating oils, possibly obtained from shale. Cancer of the
s and buccal cavity is nearly confined to males who by smoking
pose these parts to the distillation products of tobacco. The
idence here summarised suggests that certain products ob-
ined by distilling vegetable substances can sensitise the skin
cancer, *i.e.*, to the filter-passing virus now known to be the
ecific agent concerned.

Evidence from the dye industry suggests that the products
question may possibly be benzene compounds. Workers in
is industry exposed to certain amino-benzene compounds, par-
ularly benzidine and naphthylamine (compounds which, when
ey gain access to the body, are excreted by the kidneys), have
en found to develop malignant tumours of the bladder. The
w growths which occur on the skin in the tar cases, and in
e bladder in the dye-workers, have certain features in common:
first there is a simple hyperplasia; the exact moment when
lignancy supervenes is a matter of doubt; and metastasis is
e exception. Possibly we have in these benzene compounds
stances of substances which, by modifying tissue growth,
ssess the power of preparing the way for the cancer virus.

More recently still lung cancer is reported among arsenic and
balt miners in Saxony, possibly due to radium emanations
m inhaled dust. To radium emanations is also described
crosis of the jaw, a most painful disease, among workers apply-
luminous paint.

Effects of Treatment.—Treatment during the early stages of
ess and injuries sustained in occupation is not peculiar to
lustrial medicine, even though recent advances in ortho-
edic surgery have been of great benefit to those manually
ployed. But in a few cases treatment is special to the disease,
, the onset of caisson disease can be met by immediately
ubmitting the victim to the high pressure atmosphere from
ich he has just too rapidly emerged; or, again, persons over-
ne by carbon monoxide gas can be best brought round by
new method of administering a mixture of oxygen and carbon
xide through artificial respiration; while burns caused by acids
alkalis, which must be specially neutralised before ordinary
atment is applied, may be added to the list.

onvalescence.—The convalescent stage on the contrary may
profoundly expedited by occupation, particularly where re-
very is slow and tedious. The industrial convalescent tends
her to return to work too soon before he is ready for full em-
yment, when he may quickly break down again, or, by saving
nself, develop bad habits; or to delay—particularly if he is
eiving compensation—until he has lost skill, developed some
rmanent stiffness, or become neurasthenic. He needs, at an
ly stage, amusement to divert his thoughts; next, occupa-
nal therapy, in which work is performed for wages during
nited hours, in order to occupy his mind and assist in restoring
t or weakened function, *e.g.*, a hand stiff after a wound; or
tly, vocational training for new work when he cannot return
his previous occupation.

ccupational Therapy.—At each stage industry can play its
rt, but with regard to occupational therapy and training
is the only available agency. "After-care" in workshops,
l special settlements for those discharged from tuberculosis
natoria is pointing the way, which is equally valuable for ortho-
dic, mental and other cases. The need for occupational
rapy and vocational training is rapidly coming to the front
h in Great Britain and America; and industry is being called
on in its own interests in order to regain skilled workers, in the
erest of the patients, and of the community on which they
st otherwise be a charge, to play its part in restoring to useful-
s those who have broken down in its service and must either
ain their strength anew or start life afresh.

IV. WELFARE AND MEDICAL SERVICES

The need for welfare supervisors in factories is now well recognised; and, even though trade depression in recent years has held in check the creation of such posts, they continue to increase in number. The duties attached to the post must determine the staff required, but the following scale is some guide:—

Welfare supervisors for women and girls: up to 300 workers, one welfare supervisor; a further 300 workers, one assistant supervisor; a further 450 workers, a second assistant supervisor; a further 600 workers, a third assistant supervisor.

Total 1,650 women and girls, one senior welfare supervisor and three assistants. After this number one assistant should be added for every 600 workers. Welfare supervisors or apprentice masters for boys: up to 100 boys, one welfare supervisor; a further 200 boys, one assistant supervisor; a further 350 boys, a second assistant supervisor; a further 500 boys, a third assistant supervisor.

Medical Service.—Medical service in factories commenced with the appointment of certifying surgeons under the Factory Act of 1844, but it has not advanced with the importance of the work. A proposal was embodied, however, in the last Factory Bill, which may appear in the next consolidating Factory Act, to modify these posts in such a way as may be expected to improve the service. Already a few firms are employing whole-time medical men, and others part-time, to render service far in advance of anything now contemplated by legislation; they find the return from such service far outweighs the cost. The duties which must determine the size of the medical staff, often include examination of new comers, treatment of injuries and sickness originating on the premises, re-examination after a period of absence, ambulance lectures and organisation of first-aid treatment, health inspections of every part of the premises. Such duties for a personnel of 2,500 at an engineering factory are found to provide ample work for one whole-time medical officer. It is significant that no firm that has once established a medical service, has been known to abolish it; the tendency is rather to extend it. Closely allied comes dental service at factories, which is steadily increasing on account of the better health and time keeping which the service gives.

The varied activities outlined above, viewed as a whole, present an interesting and rapidly growing influence for good. The 19th century saw attentions directed to perfecting the power-driven machine and the industrial process, while the health and comfort of the worker were comparatively neglected. The seeds of deep-seated disaffection, a manifestation of ill-being, were thereby sown. To-day advances in processes and in machinery continue, but the need is being grasped for attention to the human machine. In industrial health lies the solution of many problems.

INDUSTRY, WAR CONTROL OF.—Government control of industry has appeared sporadically in every important war of modern times, under the form of commandeering of supplies and means of transportation and production. It has also occasionally assumed the form of price-fixing. But, except in the rare cases of cities under siege, governmental control never assumed the form of a general system, dominating the whole economical life of a belligerent nation, before the World War of 1914–8. In that War the general control of industry was inaugurated promptly by Germany, after a considerable delay by France and England, and, after many half-way measures that proved ineffective, by the United States in the last year of the War. In the case of every belligerent nation the extension of control was a gradual process, which had by no means reached its logical limits when hostilities came to an end.

The conditions that forced control of industry upon the several warring nations were:—

1. Universal conscription, with its tendency to disorganise all industries, essential and unessential alike, by the withdrawal of the most energetic labourers and "key-men" in the technical and administrative staffs;
2. the vast consumption of material and equipment under the technical conditions of modern warfare;
3. the insatiate demand for financial resources for maintaining and supplying the huge armies in the field and the services incidental to them;
4. the maintenance of the health and spirit of the working civil population through the provision of the necessities of life at practicable prices.

While the conversion of national industry to the uses of war was nowhere complete, it is a conservative estimate that in all the chief belligerent states from three-fourths to four-fifths of all industry was by the time of the Armistice converted to the meeting of war requirements, direct or indirect.

I. GERMANY, FRANCE AND THE UNITED STATES

Germany.—The first systematic action toward industrial control was taken by Germany. Upon the declaration of war by England it became at once evident that overseas supplies of raw materials, on which German industry had become largely dependent, would be cut off. The conservation of supplies on hand and their appropriation to essential uses was imperative. Within a fortnight, at the instance of Walter Rathenau, the Government, in co-operation with the cartels, had completed a rapid survey of the material resources of the nation and had worked out a policy, based partly on the requisition of materials and plant, but mainly on voluntary agreements, which offered a reasonable assurance of the continuous supply of military necessities on the scale then contemplated as adequate—erroneously, as the development of the War proved. Through the Reichsbank and the system of financial institutions dependent on it the necessary credit was supplied without stint to all industrial enterprises regarded as essential for war. The mobilisation plans provided from the outset for the exemption of "key-men," technical and administrative, and the suppression of unessential industries provided labourers to take the place of those who had been called to the colours. On Dec. 2 1916, the control of industrial resources was strengthened by a law instituting an industrial conscription of labour, applying to all males between 16 and 60. Auxiliary measures stiffened Government control over industrial enterprises. But to the end of the War the essential basis of industrial control was the quasi-voluntary agreement between the Government and the independent business man or group of business men, with a reserve power of compulsion in the Government's hands resting on the control of materials, credit and labour. This power of compulsion served to secure supplies, but did not restrict prices so strictly as to preclude large war profits, with attendant manifestations of popular discontent that grew more serious as the War dragged on.

France.—In France the outbreak of the War was followed by a mobilisation of men for military service which took the experts and "key-men" out of industry along with those who could be easily replaced. In consequence economic life was seriously dislocated. Unemployment reached extraordinary proportions. After the mobilisation in Aug. 1914, the principal industries employed on the average only 60% of their normal personnel, and as late as Jan. 1915, 20% of the industrial working population was unemployed.

French industry, being highly individualistic in spirit, was far slower than that of Germany to adjust itself to war needs and war control. Gradually, however, a machinery of control was set up, of which the most effective part was the disposition of ma power. Committees of economic action composed of busin men and engineers were organised in the several departmen to co-operate with the military and administrative authorit in supplying labour to agriculture and the essential industries.

Price control, so far as the munitions and supplies for t army were concerned, was effected through contracts, wi sufficient reserve power over labour, raw materials, transpor tion and credit on the side of the Government to ensure reasc able terms. The prices of products for the use of the civil po lation were subject to an informal and inadequate cont through the departmental committee of laymen co-operati with the administrative authorities. In neither case was t control rigid enough to check a rise in prices, which produc much discontent among the workers, whose wages did not r in equal proportion.

United States.—The situation in America, upon her ent into the War, was in many respects peculiar. The Allies had ready attained to a practical maximum of their industrial w effort, and the demands of war were still rapidly expanding. this effort American industry had already come to play a co spicuous part. Allied war industry was drawing heavily America for steel, copper, cotton and a large class of wholly partly finished war materials. A powerful chain of war indu tries had been built up in America; labour and materials w rapidly advancing in price, and profits rose on a huge scale.

The American Govt. was forced to meet the problem supplying the American armies with the materials of war wit out cutting off the supplies needed by the Allies. Control w essential not only to national but to international ends. Where in the early part of the War each belligerent had aimed primar at effecting the most practicable distributions of resources b tween its own military and essential civil uses, the Unit States from the outset was confronted with the problem of ma ing the best practicable distribution among the military, Alli and essential civil uses. American control was bound to envisa the entire system of needs of the Allied and Associated Powe

More fundamentally, the United States represented the la reserve of men, munitions and money. There was no possibilit of making good deficits in production from any neutral sourc except, of course, that certain raw materials like the nitrates Chile had to be drawn from neutral territories. In the circun stances the need for thorough-going control of industry w peculiarly vital.

The difficulties to be overcome in instituting control wer however, all but insurmountable. No close relation betwe government and industry had been developed, as in Germa neither was the American administrative system adapted prompt co-ordination. At the outbreak of the War the army a navy, each enjoying the power of commandeering, were in position to enter the market for supplies, in competition wi the Allied purchasing agencies, and there was no authority a where competent to allocate limited supplies in the order of in portance of needs or to keep prices within bounds. A council national defence, consisting of the Secretaries of War, the Nav the Interior, Agriculture, Commerce and Labour, with a advisory council and a widely ramifying organisation of con mittees, of executives and experts, had been created prior to t declaration of war. Out of this grew a multiplicity of organs control, a War Industries Board, a railway control, a contr of ocean tonnage, a food administration, a fuel administratio and a War Trade Board. But there was no central co-ordinati principle except the war powers of the President, which in th nature of the case could be exercised only sporadically.

Co-ordinated control of industry came into existence o March 4 1918, when the President, by a letter, reorganised th War Industries Board and specified its duties, constituting it i effect the administrative organ with power to apply the Pre ident's war powers over industry. Mr. Bernard M. Baruch w named by the President chairman of the board, with direct r sponsibility for its functioning, the other members of the boar to act in an advisory capacity.

As finally reorganised the board controlled the exercise of e power of requisitioning. The army and navy, the railroad lministration, the food and the fuel administrations, the War rade Board, the Shipping Board, the War Finance Corpora- on, the Allied Purchasing Commission and other agencies aling with industry, were required under the President's ders to co-operate with the War Industries Board. Thus it came possible to secure effective co-ordination in the whole ld of industry. The board was in a position to control exports d imports, the movement of traffic over the railways and coast- ise shipping; it was able to ration out materials, fuel, power, edit facilities to every business establishment in the country, place a check upon every construction enterprise, public or ivate, except on proof of absolute necessity, to standardise oduction in the interest of economy, and in short to do every- ing necessary to ensure that the resources of the nation at war ould be applied most effectively to the national needs, both of e people as a whole and of the military forces.

In America direct authority to fix prices was never granted by w nor established by executive order. The War Industries oard had, however, sufficient power to control prices in effect, d in case of need it actually controlled them. No specific eory of fair prices lay behind the board's control, but a concep- on of efficient economic organisation for war. The standard ward which price-fixing was working in its last phase was one hich would have permitted peace-time profits and wages but thing more. The problem of price-fixing in the United States as greatly increased because prices had already reached a very gh level before America entered the War.

Labour.—War control of industry in its highest phase of de- lopment amounted in effect to nationalisation of economic sources, labour, capital, material things. Men could not work what they liked best or put their capital to the most lucrative es or sell their materials and goods to the highest bidder. They ere called on to subordinate their private interests to the na- onal needs. The conception of public service became general- ed, as it were, and although with the end of hostilities private otives were again given free play, the conception of service tained a large measure of its vitality, exerting a considerable fluence upon action.

Labour, conceived of as "man-power," won recognition early the history of war control as the most vital of the national re- urces. The proper provisioning of labour, care for the health the labourer and his family, maintenance of proper housing andards and the like, assumed the rank of military necessities. ere too the influences set in motion in war carried over into mes of peace. In no country did public opinion settle back to its old indifference to the requirements of labour. It would hardly an exaggeration to say that the ideal of a living andard of wages attained a new influence through the experi- ice of war control.

Permanent Economic Results.—One of the most striking results war-time control was the revelation of the extent of economic aste in the conventional scheme of production. By co-ordina- on, concentration of effort upon essentials and by curbing of cessive variety in forms through standardisation, it became ssible for the United States, while maintaining 4,000,000 men nder arms, to supply the civil needs of its population with no preciable lowering of peace-time standards. While recognising at such extreme application to practical needs would in the ng run be deadening to industry, most leaders of industry me out of the War convinced of the necessity of eliminating uch waste that had gone unnoticed in the pre-War period.

War control of industry promptly fixed in the minds of those ho participated in its decisions a conception of international onomic interdependence. Control of the resources within a ation led straight to the necessity of controlling exports and im- rts, and this in turn led to an understanding of the need of ermanent economic relations under which all nations might ave equal access to the raw materials of the world. This re- ains a problem, the solution of which will tend to lessen the ances of war.

Another result of the war-time control was the more systematic survey of the potential resources, and their development where at all practicable. As a consequence, many resources are being developed in peace that formerly had been neglected. War control, with its compulsion to the use of substitutes, gave a greater freedom and elasticity to production, making a higher degree of efficiency possible in peace time. Incidentally to the control of industry, financial institutions, money and credit were everywhere subjected to control, with the result that new and more efficient methods of handling specie reserves and managing the flow of credit were devised and added to the normal equipment of peace times.

Some countries, finding themselves cut off because of the War from their usual sources of manufactured articles, soon learned to make these things for themselves, with the result that when peace returned the old manufacturing countries found that a part of their former markets for manufactured articles had been permanently lost. And so with raw materials; new sources of supply and substitutes were found. Thus, international trade is a longer time finding its normal ebb and flow.

For the most part the achievements of war control were made possible only by the solidarity of feeling and concentration upon national purposes engendered by extreme national necessity. No conclusions as to national control in peace time can be deduced from them. What may be deduced from the experience of the World War is that war under modern conditions demands drastic control of industry. War cannot now be conducted incidentally with business as usual. (B. M. B.)

II. CONTROL IN GREAT BRITAIN

During the first two years after the outbreak of the War comparatively few changes of importance were made in the British industrial and commercial system. In general, reliance was placed on the pre-War method of stimulating supplies to meet Government requirements by means of high prices. The slogan "Business as usual," which began as a useful injunction to people to keep their heads, exercised later a harmful influence in retarding the necessary transformation of industry and its subjection to an organised control without which the War could not have been won. The chief factors which finally overcame the resistance, not only of the business community, but also of the Government itself, to any drastic interference with industry were: (1) the rise in prices, which threatened to increase the cost of the War to an intolerable extent; (2) the competition of the civilian demand with vital requirements for war purposes; (3) the attitude of labour—the necessary corollary to "business as usual" is "strikes as usual"; (4) above all, the need for economising tonnage after the inception of the unlimited submarine campaign in Feb. 1917.

Fixing of Prices.—Unlike Germany, which began with the control of raw materials and was later driven to a (very inadequate) control of manufacturing processes, in Great Britain control started with the fixing of the prices of finished products and was then extended inevitably through each stage of production until it reached the raw material. Cost accountancy played an exceedingly important part in the British system of control. For each process of manufacture conversion costs were established, based on careful investigation, which allowed a reasonable profit to the normal firm. The restriction of profits on Government contracts increased the attractiveness of the civilian trade in which prices were not regulated, and, besides prejudicing military supplies, gave rise to great inequalities in the treatment of different firms. This led to powers being given under the Defence of the Realm Acts to the Government to requisition the output of any firm—which in turn immediately brought to the front the question of raw material prices. It was realised that a stable basis must be obtained on which to build up the series of conversion costs. Hence the Government was forced to purchase or control the supplies of the principal raw materials of industry so as to be able to allocate them to manufacturers at fixed prices. One of the greatest of these operations was the Government purchase in 1916 and following years of the whole of the British and Australasian wool clips (*see* WOOL). By the end of the World War over 90% of the total imports into Great Britain were brought under the control of the War Office, the Ministry of Food, the Ministry of Munitions, the Board of Trade and the Admiralty.

In the munition industries the price of iron and steel was fixed in 1916, and the continual increases in the costs of production due to rising wages were met by subsidies to the producers. No private business was allowed to use any of the necessary raw materials without a certificate or licence from the Ministry of Munitions. The engineering industry was reorganised on a very comprehensive scale, and government factories were set up in great numbers. The experience obtained in these factories as to exact costs of production was very valuable in enabling prices of contracts given to the great armament and other outside firms to be reduced during the course of the War in spite of increases in wages. The labour problem, which was especially great in the engineering industries, was met, on the one hand by the suspension (for the duration of the War) of trade-union restrictions on women's labour, output, etc., and by a great restriction of the right to strike; and on the other hand, by the power given to the Government to declare any establishment to be a "controlled establishment" under the Munitions of War Acts, and as such liable to have its whole output requisitioned at prices fixed by the Government, and to pay to the Treasury 80% of its "War profits" (*see* MUNITIONS OF WAR).

In the face of great difficulties the system of price fixing based on costings was successfully applied to agriculture, and advantage was taken of the control of prices to stimulate in particular the direct human foodstuffs—wheat and milk— and to make their production relatively more profitable than meat and butter. Thus the mistakes made, especially in Germany and Austria, of fixing maximum prices which on the one hand tended to discourage agriculture and production, and on the other led to the over-stimulation of meat and animal fats, were avoided.

Decentralisation.—An essential feature of the British system of war-time control was decentralisation and the greatest possible measure of local autonomy. In some cases, branches of the departments themselves were decentralised, *e.g.*, the Department of Wool Textile Production had its headquarters in Bradford, and in the munitions and most other industries important local offices were set up in different parts of the country. Wherever possible the existing organisation of each trade was utilised and drawn into the scheme of control. While broad lines of policy were laid down by officials of the civil service (not necessarily permanent officials), their detailed application and local operation in each trade were largely left to representative bodies of the trade, working in co-operation with the Departments concerned. In two important industries autonomous bodies were set up with executive powers. The Board of Control of the Woollen Industry, sitting in Bradford, was composed in equal proportions of representatives of the War Department, the industrial and commercial interests, and labour, and to this body, on which the departmental representatives were in a minority, was transferred complete control over the whole civilian side of the industry (within the limits of the wool allocated by the military Supply Department for civilian consumption) together with other important functions. In the cotton industry, the Cotton Control Board sitting in Manchester was constituted the legislative organ for regulating the industry. This board also was composed of industrial and labour representatives with two nominees of the Board of Trade.

Very great importance was also attached to the establishment in the different branches of each trade of advisory committees of business men who gave their services voluntarily and did much valuable work in the practical operation of schemes of control. In the Ministry of Food an agricultural council representing producers and a consumers' council were set up, to which orders were submitted before they were issued, thus ensuring the willing co-operation of all concerned.

All Industry Under Control.—Until Feb. 1917, in many industries, government control was still somewhat perfunctory, but from then onwards the increasing intensity of the War an the submarine blockade led to a great tightening up of the wh system. The great decrease of tonnage, together with the int Allied pooling of supplies, imposed a tremendous pressure o British industry which could only be met by concentrating th whole resources of the country on essential services, and on thos alone (*see* CONTROL, INTER-ALLIED). The Government ma use of its control over raw materials to interfere drastically wit the course of trade, and above all to restrict the freedom of i dustry working for civilian consumption. This it accomplishe partly by rationing the supply of raw materials to non-militar producers, or (in the case of food) to the home consumer, an partly by its man-power policy. In some industries, *e.g.*, boot clothing, the state secured the adoption of schemes for the pr duction of standardised articles, the profit at each stage of pr duction and sale being limited on the same lines as militar supplies. The popular discontent over the excessively high price for such products was thus in some measure alleviated.

By the end of the War, virtually no important branch o industry had been left without some form of regulation or co trol. The system of Government control in England, which f comprehensiveness and efficiency of operation was unequalle in any other belligerent country, would have had even more fa vourable results if it had been possible to apply it earlier in th War, and if it had been supported by a system of war financ which avoided inflation, with all its evil consequences.

INFANTRY (*see* 14.517).—To appreciate the lessons learne from the experience of infantry in the World War in relation t the past as well as to the future, it is necessary to emphasise on particular aspect of infantry evolution—the gradual decrease i size of the unit which one man can command. It is desirable als to visualise what "command" really implies. A corporal is sai to "command" the squad of recruits which he is training o a barrack square; he does it by shouting words of comman to them. Marshal Foch also "commanded" the Allied armies i Western Europe in 1918; he did it, however, without raising hi voice above its usual pitch.

Between the marshal and the corporal were a host of intermediate commanders of every sort, kind and description, bu we are concerned here mainly with infantry commanders an especially with those in the junior ranks. For theirs is the hardest task in a battle, and it is upon them that success depends "The wisest plans, the most thorough preparations, the most brilliant guidance avail nothing unless the fight is won by the fighters—by the platoons." The minds of superior officers therefore are devoted—especially in peacetime—to hard thinking on the problem of what they can possibly do or invent to make junior infantry commanders superior to the adversaries whom they may meet in action. A general's command implies much forethought as well as some experience in its holder, and thus his "command" again has a different meaning. He is a trainer, and it is with respect to this aspect of "command" that we are chiefly concerned.

UNITS AND WEAPONS

If we turn to the past for a moment, we find that the Greeks invented and trained their phalanx and the Romans their legion, and with these two systems the infantry arm dominated the known world for several centuries. Each of these formations was trained by precise drill, executed almost daily by junior commanders. Moreover this drill was in each case suited to the age and the *esprit de corps* of the period. In battle the voice of the infantry superior could be heard and was instantly obeyed, both in the phalanx and the legion. Then ensued the Dark Ages and comparative chaos dominated by feudal horse soldiers until archery made infantry again supreme. Precise drill was at the ot of the success of the archers and fire orders were strictly en- rced.

If we take Crécy (1346) as an example, we find that Edward I. initiated fire orders himself, though he left the command of e front-line to his son, the youthful Prince of Wales, in charge the archers. A careful survey of the ground at Crécy from the mmanding position of its windmill, in which King Edward was sted, enables one to see how it was possible for him to issue e orders to the archers posted below him. They were only a w hundred yards from him, but he could see better than they uld when the crowd of French cavaliers would offer the best rget to the British longbowmen. These bowmen had under veral reigns been disciplined and drilled with precision in the e of their weapons, and that is why they defeated the gallant it undisciplined mob of horsemen who attacked them without ethod at Crécy. It is also obvious that the diminutive size of e battle-field enabled the commander-in-chief, posted behind s reserve, to initiate fire orders and see their effect—in fact he rformed duties which now appertain to platoon commanders. oreover, the size of the whole battle-field corresponded with a ctor allotted to one battalion or at most to two in 1918.

Thus the process of devolution of the physical command oc- ipied some five centuries, chiefly because it took all that time to ter infantry armament from bows to Lewis guns; partly also ecause each generation of professional soldiers clung with punc- lious tenacity to the unsuitable drill of a previous age. Similar nacity is visible to-day but changes are in the air. Frederick e Great (1740) attained parade-ground precision even during e shock of encounter, and won his battles by means of remorse- ss drill, stepping to music and machine-like fire tactics with in- curate muskets. Such is the force of tradition that in 1914 erman companies in Flanders illustrated Frederick's tactics ith the aid of song to inspire their *Parademarsch* within close nge of British infantry. But their opponents' rifles were ac- rate in 1914 and the death roll was enormous.

Frederick, however, did not teach one system on the barrack quare and then practise a totally different one on active service; ut that is what the British infantry did before the South frican War (1899), and what some officers would like it to do gain. Their line of reasoning is that, as every war alters tactical rmations, it is not of much avail to learn any tactics which may erhaps be discarded in the next war.

British Infantry in 1913.—In Oct. 1913, the British infantry nderwent a drastic change, in spite of much opposition. The d "Eight Company" battalion was altered, and the system as adopted of dividing battalions into four companies, each 200 rong. This change gave a peace strength of about 100 men per mpany available for training and the organisation of a battal- on at the beginning of the War was as follows:—Headquarters, achine-gun section (two guns), four companies. A company nsisted of its headquarters and four platoons; a platoon of four ctions. A section was commanded by a non-commissioned ficer and was a normal fire unit. Four battalions, from various giments, were grouped into a brigade. In the British Army e regiment, is a unit of sentiment and the spring from which *sprit de corps* arises. It is based on a fixed regimental dépôt which the common link of battalions scattered over the British Em- ire. The four-company battalion marked a stepping-stone in e history of the British infantry, because the platoon became e "tactical" unit instead of the company. As a logical con- equence the fire unit (section) decreased in size and became e command of a junior N.C.O.—a corporal or lance-corporal. At first this change seemed incomprehensible to the lay mind, ecause it was contrary to the idea that in modern war the im- rovement of communications tends to centralisation and con- rol by the higher authorities. But the extent of the modern attle-field and the increase and improvement of mechanical eapons tend to isolate and break up infantry units more and ore. A further consequence of the change was that British fantry organisation became based on a four-unit system from e brigade to the platoon. This uniform distribution of units in ultiples of four proved to be handier than the French or the German distribution in multiples of three. By the end of 1918 the four-unit system was pronounced to be the best, whether for tactics, administration, reliefs or daily routine—but especially for tactical handling in the field. One reason for this is that "odd" numbers destroy the even distribution of duties.

Other Armies, 1914.—In the German, French and U.S. armies the regiment consisted of three battalions, and was a tactical as well as an administrative unit. In Germany it was commanded by a colonel with a lieutenant-colonel as his second-in-command. The battalion, commanded by a major, was divided into four companies, each commanded by a captain. The company was divided into three sections (*Züge*) each under a subaltern who had as his understudy or second-in-command, either a sergeant-major, a "vice-sergeant-major" or a "sword-knot ensign" (aspirant-officer). On mobilisation for war one additional officer was allotted to each company. Prior to mobilisation every infantry regiment and Jäger battalion was provided with a machine-gun company of six guns, plus one spare.

The French company was organised into four sections, commanded in war by three subalterns and one adjutant (superior company sergeant-major). The sections were grouped in pairs to constitute *pelotons* (platoons) under the senior of the two section leaders. In peace there were only two subalterns on the establishment for the four sections. Machine-gun sections were allotted to battalions as in the British Army. In the United States the company was composed of three officers and 150 rifles, divided into two sections, each of three squads. In the World War, however, the U.S. infantry regiment was remodelled on the continental model, having also a regimental machine-gun company, a headquarters company and a supply company.

Thus before the War the infantry battalion was in almost every country about 1,000 rifles strong allotted to four companies each commanded by a mounted officer. But the British battalion was the weakest in fighting strength, because its First Line Transport and other services were deducted from its 1,000 rifles, whereas the regimental systems of continental infantry provide these services from a separate establishment. The subalterns were dismounted officers whose commands varied as follows: British 50 men, German 80 men, French 50 men, United States 75 men. But in the British infantry a large proportion of the 50 men borne on the strength of the platoons were absent on other duties. For instance, they were signallers or machine-gunners, or bandsmen or transport drivers or pioneers—they were in fact everything except fighting infantrymen, and they should never have been on the rolls of the fighting platoons. The British Treasury, however, ordained otherwise and thus made training and fighting difficult for every platoon commander.

Changes during 1914–8.—During the progress of the War the basic organisation of the infantry of the belligerent powers was not materially altered. The changes were chiefly in the direction of additional weapons and a multiplication of kit, which reduced the infantry soldier to a beast of burden laden under a weight which destroyed his mobility. In 1915 the British infantry, as compared with the German, suffered from a paucity of machine-guns, and was slow to increase its machine-gun strength. At first an increase was made (up to four per battalion), and when manufacturers raised their output these were formed into machine-gun companies. They were gradually divorced from the infantry and formed into a machine-gun corps, firstly as brigade machine-gun companies and finally as divisional battalions. By the time this had been accomplished the lighter Lewis gun had made its appearance and had been allotted to infantry units. The first issue (not long before the battle of Loos 1915) was only four guns per battalion, but by the end of Nov. 1915, when brigade machine gun companies had been formed, the establishment of Lewis guns was increased.

The tendency at first was to use this weapon like a heavy machine gun, but when its characteristics were better understood it took its place as a company weapon in 1916, and as a platoon weapon in Feb. 1917. By March 1918, 36 per battalion became available. We then find the platoon composed of four sections, two of which were armed with one Lewis gun each. The allotment of an automatic weapon on such a scale marked an important step in the tactics of infantry. One of these new weapons, handled by only two men, could deliver a stream of bullets equal in number to, and more accurately aimed than, what could formerly be projected by 25 soldiers with rifles. Obviously the number of men required in the forefront of the battle could be reduced without affecting the volume of fire. This meant fewer casualties and bigger reserves and the maximum number of soldiers in every section was reduced to one leader and six men, making a total for all ranks of a platoon only 31 actually taken into action.

The Germans were faced with the man-power problem before any of the other belligerents, and they also appreciated the value of the light machine-gun. In March 1917 they issued three to every company, and afterwards raised this allotment to six by giving two guns to each platoon. Finally, each German battalion consisted of a heavy machine-gun company of 12 guns and three infantry companies armed with six light machine guns each, without counting the special machine-gun companies allotted to divisions for every battle. This tremendous increase in automatic weapons had an inevitable effect on infantry formations. The costly attacks on narrow frontages were abandoned. The successive lines or waves of men gave place to open formations. The four sections of a platoon were gradually separated from one another and compelled to manoeuvre and fight under their own leaders. When platoons were too weak to man four sections they fought with only two, one of which was armed with a Lewis gun. The frontages allotted to the leading platoons were increased and in some of the great battles of 1918 we find platoons attacking on frontages of 200 and even 300 yd. with very small effectives. Fire-power was at last understood.

Special Weapons.—In addition to the Lewis gun, rifle-grenade and hand-grenade, the Stokes light mortar proved to be a useful infantry weapon. Although it did not form an integral part of battalions, the brigade light-mortar batteries drew their personnel from the infantry and the mortars were allotted to battalions during operations. The light mortar was the nearest approach to an infantry gun in the British Army and, though not an ideal weapon, rendered great help in reducing enemy machine guns and strong points. The German mortars in the summer of 1918 were distributed as follows: each regiment had a regimental "*minenwerfer*" company, organised in three sections, each with three light *minenwerfer*, and in addition two or three medium *minenwerfer*. The important part played by these weapons in battle tended to prove that infantry, when scientifically armed and on ground that affords cover for movement, can act independently of other arms, and is capable of fighting its own local battle either with or without artillery support and tanks. To fulfil this rôle, however, it needs to be more highly and scientifically trained than before the World War. The importance of training the commanders of companies, platoons and sections cannot be over-emphasised, and it was the shortage of these trained officers and non-commissioned officers which caused so much deterioration after the battle of Ypres in 1917. It was also the cause of avoidable casualties in every subsequent battle.

Post-War Organisation.—The British infantry battalion is now organised in a battalion headquarter wing, and four companies. The wing includes a machine-gun platoon. Each company consists of company headquarters and four platoons, each platoon of headquarters and four sections, two of which are armed with one Lewis gun each. The platoon is the largest unit composed of men whose sole duty is to fight, and the War established it as the "tactical unit" of infantry. The section is the fire unit and consists of a leader and six men, a number which experience has proved is the largest that can be directly controlled in action by one commander. Thus the British subaltern officer's command in battle became 28 fighting men, as compared with 50 in 1914—but the Lewis guns, rifle-grenade and hand-grenade increased the fire-power of the platoon out of all proportion to the number of its men.

The French battalion comprises a headquarters group, three ordinary companies, a machine-gun company and a section of accompanying weapons (mortar or infantry gun). The compan at war strength is composed of a headquarters section and fou combat sections, and the section of three groups. The fightin group consists of a team of riflemen and a team of automat riflemen, the team in either case comprising a corporal and fiv men. In peace or when the strength is lowered by casualties, th number of sections in the company, or groups in the section ma be reduced, but the actual groups are maintained at full strength The French nowadays place all their reliance upon the ligh automatic rather than on the rifle, and their new organisation the outcome. Although their group is far stronger than the Bri ish section, to which it corresponds, the side of all its ten men cen tres round the service and introduction of the one *fusil-mitrailleu* and the rifle team inevitably loses much of the value of its greate mobility. On the other hand, the British organisation, thoug possessing greater freedom and power of manoeuvre, means tha the platoon commander has the difficult rôle of combining fou sections of which two are radically dissimilar in arms and i action to the other two. The German battalion, also, consists o three companies and a machine-gun company. A company i organised in three sections; each section (*Zug*) is divided int four or five groups (*Gruppe*) of eight men each—two ligh machine groups and either two or three rifle groups.

The Rôle of Infantry

The question is sometimes put, "What is the use of infantry Is it not butchery to expose men on foot to the mechanical ho rors of the battle-field of to-day?"

Limitations of Machines.—Man on foot is still more uni versally mobile than any machine. The more destructive weapon become the more does man seek impregnable shelter in which h can escape the missiles of death-dealing machines. An enem may conceal himself in a hiding place which is inaccessible t any machine; but where man has entered there also man ca follow to seek him out, and until the assailant possesses a me chanical octopus he must himself go in to dislodge his adversary The appliances manufactured by inventive genius only help t break down the barriers to this final act of combat. A grea artillery bombardment will drive the enemy to ground, but eve where concentration of shell-fire is achieved, it cannot dislodg him. He is safer in his dug-out than in flight. The tank is tangible, it is true, and therefore less petrifying, but man can avoid i or hide from it more easily than from infantry. Moreover it i less agile, more cumbersome, more limited in its modes of actio than the foot-soldier. There are types of obstacles which it cannot yet surmount, ground which will not bear its weight, o which is too rough or steep to cross. Cavalry like infantry is a human arm, but it affords too easy a target, is too quickly stopped by rifle or machine-gun fire and is less mobile on rugged and broken ground. Its superior speed is insufficient compensation for these drawbacks except against broken and flying infantry. Thus we see that infantry is still essential in battle, that its power is based on human rather than on material factors, and that its tactics spring from moral elements of which one is fear.

Destruction of Enemy Morale.—To wear down the enemy's nerve control is the rôle of the commander, of the artillery, of bombing aeroplanes. When opposing armies are in close contact the infantry shares in the process by raids and false attacks. In the battle the part of the infantry is to snap, not wear down, the enemy's control over his fear. The fracture is effected by the enemy's realisation that he is powerless to ward off his assailant's blow. To accomplish this we must pass a sufficient though not necessarily a larger proportion of men through the curtain of his fire to a point so close to him that they can assault or offer the threat of an assault which he realises he is powerless to prevent. The key to this assault is fire at short range to pave a way for the onslaught. Hence formations which avoid loss by taking advantage of cover and conserve the will to close with the enemy are necessary. Surprise, the simpler, more certain and less costly method, is effected by assault from an unexpected direction against an unguarded spot. The key to infantry success is therefore movement or in military language nocuvre. Fear above all is caused by uncertainty and appre- ision of the unknown which breaks down the will to resist l gives to the assault in flank or rear its supreme value. Thus close quarters mere numbers are not the deciding factor, l assaults are better launched by platoons than by battalions.

trengthening One's Own Morale.—What are the factors which ble the average man to fight down fear? First undoubtedly nes confidence—confidence in his superiority to the enemy, ed on his own skill in handling his weapons; faith in his der's skill and judgment combined with devotion to him as nan; trust in and comradeship with his fellows—the assurance t he will be backed up, that his efforts will not be in vain. ondly, *esprit de corps*—which is allied to confidence. Thirdly, cipline—the power of association to overrule instinct. Lastly, ion to minimise reflection on the dangers to be faced.

THE TRAINING OF INFANTRY

onfidence is born of training—the training of each individual, training of the leader, the training of the unit. These cessive trainings forge the infantry weapon and make it fit act its part on the battle-field. Moreover these various inings of human beings symbolise the truth that man is still master of the machine. But no greater error is current to- than that infantry is the most easily trained arm. None ds more care, more skill if it is adequately to play its part. r it is the least mechanical and by far the most human arm in stence. Yet experience of the World War indicates that of all arms and services, infantry, the backbone, was the least ined. This defect was due not so much to the reason that care, less research and thought were devoted to it—though se factors counted—but to the reason that it is the most icult arm to train, because it possesses so few concrete ele- nts. It is concerned with tactics and ground.

lements of Training.—To train infantry is to exercise an , whereas to train gunners is to apply a science; the one uires an artist, the other a calculator. The man in the ranks the artillery, the tank corps, the air service, is often a me- nic—executing a concrete task in a definite manner. Initiative he province of the officer, but even he in the subordinate ks of other arms is concerned with producing a material ct. The infantryman's use of material—his weapons—is only eans to an end not an end in itself. He himself survives the ntific developments of countless wars because his human ue remains unchanged. Even in the employment of his pons he is guided by variable factors and conditions. But use of his variety of weapons is only complementary to the he makes of tactics and ground before he gets to grips with enemy.

he variety of elements with which he has to deal has led a rule to each different unit being trained—too often mis- ined—according to the whims and prejudices of its temporary nmander, who is apt to confine himself to such parts of the ject as he himself knows best. Hence a tendency towards r-emphasis of such matters as drill, musketry, bayonet nting, which can be easily mastered by the intellect of the rage officer. Hence also the neglect of tactical training, ich demands thought and is difficult to learn and teach be- se it deals with moral and variable factors and requires a dicum of imagination.

inor Tactics and Fire Tactics.—The tactics of infantry must based on human nature and not on mechanics or geometrical fection. Yet it is almost incredible how in the past showy lutions deduced from the parade-ground have persisted on battle-field. It is a truism to say that a revolution has been ught in infantry tactics by the inventions which mechanical ence has brought to bear on war. But it is no less true that consequences of this revolution take years to understand. is lesson may be summarised in the phrase—"the power manoeuvre." It needs a complete reorientation of military ught and fresh views before we begin to extract right methods m the melting pot of war. Yet that infantry which soonest rns its lesson will be supreme.

A mastery of elementary tactics is essential if infantry is to attain its goal in battle. It must be permeated by the best doctrine which the last war can teach, and its junior commanders must no longer be subjected to the whims or prejudices of whoever happens to be in temporary command. Moreover the doctrine should be adopted by authority and be expressed in language so simple and by metaphors and illustration so clear, that it can be as readily grasped by subalterns and corporals as by general officers. Its manual of instructions should be as intelligible to the Australian bushman as it is to the staff college graduate.

Development of Leadership.—In 1806–15 the British were capable of a sustained effort in the theory of tactics as originated by Sir John Moore, and there is reason to believe that British infantry could to-day be trained to as high a pitch of comparative excellence—but not without a definite doctrine of minor tactics and some evidence of leadership to inspire its wholesale adoption. This quality of leadership in peace-time needs the special ingredients of spirit, intelligence and human sympathy, together with sufficient character and determination to carry conviction to the mass. Just as Sir John French inspired a new doctrine of peace training at Aldershot after the South African War, so now could a leader develop the experiences of the last war and reduce fire tactics to simple exercises for platoon and company commanders.

Such a doctrine would probably be based on the little group of men following a corporal whom it knows because he has trained it. In the hurly-burly of modern war these little groups retain cohesion because men will follow a leader whom they see close to them, whose voice they can hear and whose presence is familiar. These groups (named sections), trained by higher leaders whom they trust, will forget themselves and accept any risks in battle if they are convinced by habit that their effort will not be in vain, that their successes will be immediately supported. A fire unit which forms part of a trained team will sink itself unhesitatingly if it knows that the rest of the team will not leave it in the lurch or allow it to bear the brunt alone; that, when it has spent itself to make an opening, others will relieve it of the burden. But can we reasonably expect generals who were trained in pre-War tactics to take the lead and compel their subordinates to alter their methods of training?

TACTICS AND MANOEUVRE

For decades the infantries of all countries attempted to produce tactics adequate to the new weapons at their disposal by multiplying the lines which were successfully used by their forerunners in the days of the musket—with its short-range and slow rate of fire—and the case shot and solid shot of the artillery. They moved shoulder to shoulder with intervals. The idea of manoeuvre was absent. Even down to the closing stages of the World War the action of infantry units in battle—as distinct from a skirmish or an affair of outposts—was confined to frontal attacks. Manoeuvre was the weapon of the higher commanders only. A division or a brigade moved as a body; hence it was its commander alone who had the power of striking an enemy force at two or more different angles concurrently. We have already seen how slowly the idea of decentralised fire orders developed. It was the same with decentralised manoeuvre.

In any large action each of the infantry units was allotted only a fraction of the frontage of the force of which it formed a part. This narrow sector was hedged in on either side by neighbouring units of a corresponding size. How then was it possible for attack or defence on the part of infantry units to be aught but straight to their front? How can they manoeuvre if they have no space to move in? And how can they be expected to move to a flank if they possess no intervals and no flanks?

The Continuous Line.—Thus it came to pass that in spite of the fire effect produced by scattered Boers sitting on distant *kopjes* in South Africa (1899), and in spite of Japanese losses in assaults at Port Arthur and elsewhere in Manchuria (1904), European tacticians failed to shake off certain notions about continuous lines and storming masses. They appreciated the importance of putting what they called "weight" into the decisive attack, but failed to realise that the weight or forcefulness of an attack no longer increases in proportion to the number of infantrymen thrown into it. In South Africa wide and premature extensions were adopted to minimise losses on the flat veldt, but such extensions did not lead to any idea of manoeuvre. On the contrary, the unmanageable thin lines one behind the other were incapable of intelligent manoeuvre—as was discovered in peace training after the South African War.

Even then the idea of manoeuvre to a flank by a small body was not grasped, or at any rate was not taught as a definite doctrine. Skirmishing lines in extended order made rushes and utilised ground; they fired in small bodies and opened at long ranges; at the decisive points they were gradually thickened up into a crowd. These crowds surged forward at a given signal and assaulted to their front. But the infantry soldier was so near his neighbour in these sham battles that he had scarcely sufficient space to load and fire his rifle without hitting one of his friends; the units became so mixed together in the process of thickening up that neither the corporal nor the subaltern could exercise control over his own men or any unit; often he could not find them during the decisive stage of the battle. Fortunately the "cease fire" sounded and reorganisation took place; but in 1914–8 there was no "cease fire" and no umpires and the warring infantries were slow to learn. This was no doubt inevitable, and is a sufficient reason to try now to gather the lessons of 1918, and it may not be out of place to suggest that the tactical experiences of 1918 have not been embodied in the tactical handling of units in 1926.

Group Formations.—Official manuals seem always to lag behind the age, and in fact human nature conquered the line formation before its breaking up was officially sanctioned. Tradition held fast to her pre-War habit, but the need for a control which could not be obtained with the extended line helped to breach the ramparts of orthodoxy. The group attained its final and complete recognition after its success against the German "pill-box" defence in the dreary wastes of the Ypres salient in the autumn of 1917. Also the Germans in their 1918 offensive deliberately trained their infantry in similar groups with orders to penetrate everywhere by infiltration. British dispersion, enforced by new weapons and human nature, rendered penetration possible by attacking infantry groups—termed "sections" in the British army—between the posts or machine-gun "nests" of the defenders. By exploiting every initial penetration the commander on the spot attacked in front and flank simultaneously such posts of the enemy as opposed him in his own sector. This newly acquired power of manoeuvre restored to infantry the master-key of victory, and retains for it still the important rôle which the old stereotyped tactics were rapidly losing. But it took three years of war and unprecedented losses to drive home a lesson which peace training may probably obliterate.

The Infantry Attack.—The outstanding lesson gained from the new-won possession of infantry units—the power of manoeuvre—is that tactics can be based on the fundamental principles which govern the action of other independent bodies which manoeuvre. The platoon is no longer fixed in a segment of the machine of battle but is an independent moving part fighting its own small action.

Its forward sections should press on unceasingly in order to find and penetrate any weak spots in the defence and to advance to the objectives assigned to them. If the forward body of a platoon is checked by an enemy post, it fixes it firmly by fire so that the enemy's attention is absorbed "by a menacing hand at his throat" whilst the manoeuvre body (termed the platoon reserve) works round his flank to deliver a surprise blow. This act of fixing can be achieved by a combination of fire with movement. There must be the threat of the forward spring in order to fix the enemy's attention. Fire alone, from the hastily chosen halting places of an attacker, cannot be relied on to absorb the whole attention of a defender behind selected cover. Unless each forward infantry section is imbued with a determination to
press forward, the posts of the defence may be able to b
cross-fire on groups which have penetrated the position.
there is still a further means by which the enemy can be fix

Artificial Smoke Screen.—The World War added a us
weapon to the infantry—armament-smoke. This new eler
gives the user the conditions of day but imposes on his ad
sary the conditions of night. Mist or fog has often been a deci
but accidental factor in battle, but with the introductio
artificial fog which can be projected at the will of the user,
enemy's view is impeded whilst his own movements take p
in daylight. In attack, the forward sections may fix the en
posts more effectively by firing smoke to windward of them t
by rifles or Lewis guns. Thus smoke helps small local assau

Decisive Manoeuvre.—The manoeuvre body of an infa
company follows close behind its forward platoons and rem
under the hand of the captain. If and when the whole of a
ward platoon is held up by the fire of an enemy centre of re
ance, the captain uses his manoeuvre body to turn a fl
To achieve this he might have to quit his allotted sector
follow in the wake of a more successful unit on his flank. Pas
through the gap he turns and assaults an exposed flank of
centre of resistance. Such a blow has the moral effect—con
as a surprise and threatening the line of retreat—which is
key to victory. But if the defenders of the post turn to r
this flanking attack, the forward body should rush in and ass
them from the front. Such combinations are simple if p
training is staged on the basic principle of "fixing and
noeuvre," as the key formula of fire tactics.

This combination of fixing and manoeuvre is the bed-
principle of every street fight. Watch a couple of small b
tackling a bigger one. What happens? One of the small b
rushes straight at the big boy, and when his attention is fi
the other runs in from behind and delivers a blow. The
small boy puts all his energy into this effort, for he knows
stinctively that if he fails the opponent will beat them e
separately. But if the big boy attacks one of the small o
the other in like manner rushes in from behind. Thus fi
and decisive manoeuvre should become a formula engraved
the mind of every infantry corporal and subaltern, and he sh
also be trained to act upon it instinctively. It has won gen
acceptance since the end of the War and concerns above all
tactics of the platoon, which is the smallest unit which can
and manoeuvre without waiting for orders from a superior.

Defence.—Attacking infantry, owing to its open formati
can offer immediate resistance to hostile counter-attack.
halts and each unit consolidates its own ground forthwith, v
its defensive posts distributed in depth and disposed to g
each other support by fire. The rôle of the forward bodies i
break up the enemy's organised attack. If the attacker ma
a gap or effects a lodgment into the position of any forw
bodies, the reserves counter-attack to throw him out. Sho
the attack break through the forward positions on a br
front, the reserves take him in flank by fire. Just as manoeu
is superior to frontal attacks, so is defence-fire which enfila
from a flank the more damaging to the attackers' morale.
this as in all cases the training and determination of the bet
infantry wins the day, but the great advantage possessed by
defence—almost its only advantage—is that its action can
thought out beforehand. Its reserves can be placed on a fla
in readiness for action, and can be practised on the act
ground to counter-attack from favourable positions with a
iliary arms to help them.

Picture of an Infantry Battle.—Who is there with experien
of big attacks embracing miles of country in France that h
not seen the most resolute infantry suddenly assailed by a bu
of surprise-fire from the flank or rear? Its self-forgetting det
mination grows uncertain; it ceases to move and looks furtiv
for cover. If the surprise-fire continues from invisible shoote
the men become irresolute and nervous. The will to advance
gone. If the threat of a counter-assault from a flank shou
immediately follow they look to their rear and break or drib
away. Unless their own commander coming on from behi

n throw in an opportune reserve to counter the counter-attack d restore the local situation, the attack is stopped. That is w, so often in France, one German machine-gun nest—just e little group inspired by the will to resist, nourished in the inciple of surprise—would hold up the attack of a company d sometimes of a whole battalion.

It is thus we learn to visualise the infantry unit—battalion, mpany or platoon—in the battle of to-day. It possesses the wer of offensive movement and yet is protected by its open mations. Its articulation into interdependent moving bodies pable of manoeuvre is the main infantry feature developed the World War. The illimitable extension of fronts, brought out by the vast numbers which nations in arms put into the ld, forced the military leaders to seek and discover a solution the deadlock—and they found it at last by granting the power manoeuvre to infantry units down to the platoon. This revotionary idea began to emerge in the Flanders attacks of 1917 t was still only in its chrysalis stage when the War terminated 1918. It still lacks a clear, simple working formula which can practised by lance corporals in their daily exercises.

Future Development

A question naturally arises as to the probable direction which e development of infantry will take under conditions caused new inventions, particularly mechanical ones. In what way ust we improve and reform our infantry methods in order to hten the infantryman's burden in view of the probability at he may have to wear a gas mask in every future attack? ne question may be considered under two heads: firstly, means increase mobility; secondly, tactical doctrine.

Mobility.—Almost every mechanical advance means a step wards greater mobility. Every arm and branch of the service becoming more mobile—or else decaying—under the influence the petrol era. In the transport of an army the horse has ready given way to the road motor, and this in turn promises yield to a cross-country tractor with caterpillar tracks. The avy artillery is already motor-drawn, and the lighter field tillery will follow suit. Mobility is the foundation stone of the lue of infantry. Its unique position has always rested upon e fact that it is more *universally* mobile than other arms. ıt on the normal field of battle, if it is to maintain its unrivalled sition as the "handyman" of war, its mobility must keep ce in proportion with that of the other arms. To give it creased mobility two problems must be solved. Firstly, means ust be devised for bringing infantry to the scene of its action ore quickly and with less fatigue than by the use of its legs. the second place, infantry equipment must be lightened. ne soldier must not again be treated as a beast of burden—her means than piling loads on his back must be devised.

Equipment.—If infantry is to possess an adequate agility weapons and ammunition must be lightened to an appreable extent or they must be carried for him. In fact the fantryman of the future must be regarded as an athlete. very article which he does not need in the combat itself must discarded or carried for him on accompanying transport.

Wanted: a Battle Drill.—A further development in tactical ethods which has been mooted is a controllable system of ovement on the battle-field. At present armies retain drill ovements for the parade-ground and throw them aside when ey go on active service. As human nature in battle retains ly that which has become instinctive habit it is scarcely surrising that in moments of crisis one has seen men advancing, gainst the deadly fire of machine-guns, in close-packed bodies. ut if drill were brought up to date on the lines of open order id the group, it is probable that moments and even hours of riceless value would be saved. But even during the actual tack, there might well be occasions when an ingrained method control could be used to quicken the manoeuvre of deployed its and direct them to take advantage of local situations. oice control would be out of the question, but if signals were w and simple, visual control might be used, particularly if a earer means of signalling were devised.

Let anyone with experience of war ask himself if there were not moments in his recollection when he might, had his men been drilled in such a system, have saved precious minutes, an opportunity which never returned, by the use of a signal instead of the slow method of sending a message by runner. The old close order was under control, but modern fire made it impossible. With extended order the battle degenerated into the chaotic movements of an uncontrolled mob. An ingrained system of battle drill, in which intervals and distances were purposely exaggerated, would enable sub-units to be manoeuvred, to be opened or closed in "concertina" fashion according to the ground and local circumstances. Such a system might go far to combine the flexibility of the old with the invulnerability of the modern formation.

It seems improbable that in the future we shall see the extensive and elaborate field fortifications of 1914–8. The new mobility brought in by the tank, the caterpillar tractor and the aeroplane, would appear to prevent the stagnation which produced labyrinthine entrenchments in the World War. (*See* Machine Guns; Strategy; Tactics; War.) (I. Max.)

INFANT WELFARE: *see* maternity and infant welfare.

INFECTIOUS FEVERS.—In this article the various infectious fevers are dealt with.

Chicken-pox, or Varicella (*see* 6.130).—Several writers have maintained within recent years that a close relationship exists between herpes zoster (shingles) and chicken-pox, and that the virus of the two diseases is identical, on the grounds that: (1) Chicken-pox in one individual may follow herpes zoster in another within the ordinary incubation period for the former, *i.e.*, within 21 days. (2) In such cases no other source of infection may be discoverable. (3) Much less frequently herpes zoster may be apparently contracted from a case of chicken-pox. (4) Herpes and chicken-pox may sometimes coexist in the same individual. The problem, however, cannot be solved until the causal agent of chicken-pox has been discovered.

Diphtheria (*see* 8.290).—The principal cause of the spread of this disease is now generally admitted to be the human carrier, whether sick or healthy. In the great majority of cases the disease is disseminated by the diphtheria bacillus being expelled from the mouth or nostrils by coughing, sneezing, spitting, kissing or speaking. Apart from tonsillectomy, which is not always practicable, there is no certain method of ridding the carrier of bacilli. On this account a remarkable change has taken place in the methods of prevention of diphtheria. In 1913 Bela Schick of Vienna devised a test whereby immunity or susceptibility to diphtheria can be determined. The test is performed by injecting intracutaneously a minute dose of diphtheria toxin. If the subject is immune, no reaction occurs, whereas susceptibility is shown by the appearance of a small red swelling at the site of injection within 24–48 hours. Those found to be susceptible are given three subcutaneous injections of a mixture of toxin and antitoxin, which was first introduced by Von Behring in 1913, but not used on an extensive scale until some years later by Park and Zingher in the United States. After the lapse of some weeks or months immunity as determined by the Schick test is established and lasts for some years, if not throughout life, whereas the immunity afforded by injection of diphtheria antitoxin is not likely to last longer than three or four weeks.

The experience of the years from 1910 to 1925 has confirmed the earlier observations as to the value of the antitoxin treatment of diphtheria. Death and severe paralysis are practically unknown when the patient receives an adequate dose within the first 24 hours, but become increasingly frequent with each 24 hours' delay. The intramuscular method is the best mode of administration, as it is quite as simple as the subcutaneous and ensures more rapid absorption of the antitoxin.

Measles (*see* 17.947).—Caronia of Rome has isolated (1923) a minute diplococcus, which he regards as the specific cause of measles, from the blood, bone-marrow, naso-pharynx and cerebrospinal fluid of children during the prodromal and eruptive periods. Injection of healthy children with attenuated cultures of this organism produced immunity to measles, but inoculation of large and repeated doses gave rise to a typical though mild form of the disorder. Further confirmation of Caronia's investigations is required before his organism can be accepted as the cause of measles. Subcutaneous injection of the serum of convalescents within the first six days after exposure to infection is a preventive method first employed by Nicolle and Conseil in 1918 and subsequently carried out on a large scale by Degkwitz in Germany and other clinicians on the Continent and in the United States. In nearly all cases this method either prevents an attack of measles altogether or renders it very mild. In the absence of convalescent serum, which is often difficult to obtain, the whole blood or serum of adults, especially the parents, who have had measles, can be used.

Scarlet Fever (*see* 24.303).—The recent work of G.F. and G.H. Dick indicates that scarlet fever is a local infection of the throat caused by a particular type of *Streptococcus haemolyticus*, which is capable of producing a soluble toxin, absorption of which gives rise to the general manifestations of the disease. These observers successfully inoculated volunteers by swabbing their tonsils and pharynx with a culture of the organism. Subsequently they devised the "Dick test," which determines the susceptibility or immunity of an individual to scarlet fever, and is performed by injecting into the skin a filtrate of the culture which produced the disease. If the person is immune no reaction occurs, while susceptibility is shown by the appearance of a red area within 12–24 hours. Desquamation, which was formerly considered as the chief agent in the dissemination of the disease, is now generally regarded as harmless, unless the scales have been contaminated by discharges from the nose and ears. The duration of infectivity is now held to be much shorter than formerly. It is probable that most cases cease to be infectious in the course of the fourth week, unless they are complicated by discharges from the nose or ears. Specific immunisation against scarlet fever is still in the experimental stage, but very promising results have been obtained by subcutaneous injection of susceptible persons with a small amount of the toxic filtrate of the variety of *Streptococcus haemolyticus* which causes scarlet fever. Further observations are required to determine the duration of the immunity acquired by this method. Passive immunity can be acquired more rapidly by injection of a special scarlet fever antitoxin, but is probably less permanent.

The method employed by the late Dr. Robert Milne, consisting in inunction of the skin with olive oil and application of 1·20 carbolic oil to the throat, has proved to be valueless, as it does not prevent the spread of infection or the occurrence of complications and return cases. Encouraging results have been obtained from the use of an antitoxic serum prepared by injection of horses with gradually increasing doses of sterile scarlet fever toxin. It has been found that if the serum was given early the course of the disease was shortened, and the incidence of complications and sequelae greatly diminished.

Typhoid and Paratyphoid Fevers (*see* 27.503).—The great diminution in the incidence of these diseases in recent years in many countries has been due partly to immunisation in the army and navy during 1914–19 of a large proportion of a particularly susceptible age-group and partly to the careful supervision of the water and milk supplies, which has reduced the disease to such an extent that the health authorities are able to devote more attention to the prevention of contact and carrier cases. Numerous statistics have been published in various countries showing the efficacy of antityphoid and antiparatyphoid vaccination. Among the most striking are those given by Russell. During the two years in which the United States took part in the World War there were 1,065 cases of typhoid or paratyphoid or one among 3,756 men, with 156 deaths or one death among 25,641 men, as compared with one case for every seven men and one death among every 71 men in the Spanish-American War of 1898. The duration of immunity following inoculation varies from two to four years or longer, but under certain circumstances, such as ingestion of massive doses of typhoid bacilli and impairment of resistance, which are specially liable to occur among soldiers on active service, the immunity is lost in a much shorter time. The serum treatment of typhoid and paratyphoid fe
is still in the experimental stage, the great decrease in these
eases having prevented a trial of it on a large scale in re
years. Vaccine treatment unlike vaccine prophylaxis has
become generalised, and the results obtained are inconst
Some observers, indeed, regard the vaccine treatment of typ
as an example of non-specific proteintherapy, as the same res
have been obtained by injection of *B. coli* and staphylococ

Diet.—The modern tendency is to feed rather than to st
the typhoid patient, who is now no longer condemned to an
clusively milk diet for several weeks, but may be allowed o
readily digestible articles of diet from an early stage. A n
liberal diet enables the patient to offer a better resistance to
disease, to be less liable to complications and to make a n
rapid recovery.

Treatment of Carriers.—After the carrier state has lasted
months without being affected by drug treatment such as
amethylene tetramine for urinary carriers, and chloroform, m
thol and lacto-bacillin for intestinal carriers, operations such
removal of the gall-bladder (cholecystectomy) in the cases
intestinal carriers, or of the kidney (nephrectomy) in the cas
urinary carriers must be considered.

Paratyphoid Fevers.—These are acute infectious diseases
to the action of bacilli, of which three varieties have been
scribed, viz., *Bacillus paratyphosus A*, *Bacillus paratypho*
B, and *Bacillus paratyphosus C*. Though on the whole
severe except in war time, they closely resemble typhoid fe
in their clinical appearance and course, and can only be dis
guished therefrom by bacteriological examination. Anot
point of difference is that while typhoid fever is an exclusiv
human disease, paratyphoid fevers may infect both man
animals, *e.g.*, dogs, cows, rabbits and pigs, and be transmit
from man to animals and vice versa.

Typhus (*see* 27.508).—As the result of their study of the epid
ics which occurred in Tunis from 1906 to 1909 Nicolle and
collaborators have shown that typhus is transmitted by the
or faeces of infected lice, and not by other insects such as bu
fleas or mosquitoes, or by discharges from the mucous me
branes as in other infectious diseases. Recent research indic
that the minute intracellular organism known as *Ricket*
prowazeki is the cause of typhus, this conclusion being based
experiments showing that the virus of typhus and *Ricket*
prowazeki are inseparable in infected lice, as well as on the pr
ence of bodies indistinguishable from *Rickettsia prowazeki*
typhus lesions in man, where they have been found with gr
regularity in the blood-vessels of the various tissues.

The Weil-Felix reaction, which was described by Weil a
Felix of Prague in 1915, occupies as important a position in t
diagnosis of typhus as the Widal reaction in that of typh
fever, or the Wassermann reaction in that of syphilis. It co
sists in the agglutination by the patient's serum in a diluti
above 100 of a proteus-like organism named X 19 isolated fr
the urine of a typhus case. The reaction appears toward the e
of the first week, rises rapidly to its maximum between the 1
and 13th days, and gradually falls in convalescence, but may
main positive for months and thereby enable a retrospecti
diagnosis of typhus to be made. The prophylaxis of typhus co
sists in the complete delousing of patients and contacts, as well
in the disinfection of clothing, which is best carried out by stea
The serum and vaccine treatment of typhus is still in the expe
mental stage.

Whooping Cough (*see* 28.616).—It is now generally recognis
that the micro-organism in the form of a cocco-bacillus, d
scribed by Bordet and Gengou in 1906, is the causal agent
whooping cough. It is found in a practically pure culture in t
catarrhal stage and first week of the paroxysmal stage, and the
rapidly diminishes in number, being outgrown by numero
other organisms, especially *Bacillus influenzae* and the pneum
coccus. In the great majority of cases, therefore, the diseas
ceases to be contagious long before the characteristic whoopi
has ceased. Recent writers have drawn attention to the fa
that whooping cough is not so rare in adults as it is commonly su

ed to be, but that it may assume at this period atypical forms
ich are responsible for a spread of the disease. A vaccine pre-
ed from the Bordet-Gengou bacillus usually in association
h other micro-organisms has been used on a large scale in the
vention and treatment of whooping cough, but clinicians
by no means unanimous as to its value. Among the numer-
drugs recommended for the treatment of the disease ether
ninistered by intramuscular injection has recently enjoyed
onsiderable vogue on the ground that it reduces the number
l severity of the paroxysms. (J. D. Ro.)

NFLATION: *see* CURRENCY.

NFLUENZA (*see* 14.552).—The term influenza will be used to
ly "a pandemic outburst of disease characterised, clinically,
a rapid course, catarrh of the respiratory tract, pyrexia and
ne degree of prostration; and epidemiologically, by a tendency
occur in several successive waves at short intervals of time."
is provisional definition is applicable to the visitation of 1918–9,
l to other outbreaks of febrile respiratory catarrh more re-
te in time and about the distribution of which less is known,
is not applicable to the sporadic cases or even the localised
demics of respiratory catarrh to which the name influenza has
n so often applied, especially in the years following fairly
sely upon pandemic outbursts.

The Influenza Pandemic of 1918–9.—This pandemic swept over
world in three successive waves, the first appearing quite
ldenly in May and June 1918, the second starting at the end
September or early in October and waning in December, and
third wave, less uniform in character, appeared early in
rch 1919. This outbreak, attributed by France to Spain,
Spain to France and by America to Eastern Europe, seems to
ve appeared almost simultaneously amongst the nations of
"Entente" on the Western front, and amongst all those
nmunities in intimate touch with them and in the closely
ked theatres of war. It showed the explosive character that
possible only for a highly invasive infection assisted by con-
ions of swift communication such as obtain in modern war.
This first wave made its appearance a little later amongst the
ntral Powers and their neighbours. Early in July it attained
full proportions in Germany, Austria, Norway, Sweden and
nmark, Holland and Switzerland. In several large areas of
world's surface, in the South American republics, in Ber-
ıda, the British West Indies, the Azores and in the islands of
Pacific and Australia, the summer of 1918 seems to have
ssed without an influenzal outbreak. In New Zealand, cases
said to have appeared in Aug., the harbingers, perhaps, of
autumn, rather than the first manifestations of the summer,
vc.

This first wave passed rapidly, so that a "frequency curve"
weeks, in which the incidence in the worst week is taken as
o %, shows a steep ascent to a maximum, followed by an
ually steep and almost symmetrical fall, the whole episode
ssing within about five or six weeks. So benign was the type
t many cases among soldiers at the battle-front escaped
ord, as the men never "reported sick" but merely rested for
day or so in their units, and this was fortunate, as the army
spitals were soon overcrowded. The death-rate was incon-
lerable, but there was an ominous tendency to a higher mor-
lity amongst the later cases, just before the wave came to an
d, seeming to suggest an increase in virulence. The first batch
cases looked "like a mild attack of measles without a rash."
spiratory catarrh, congested conjunctivae, headache, lassitude,
rexia of short duration, a feeling of prostration with the return
temperature to normal, and then a rapid recovery of health;
ch was the course in the vast majority of the cases during the
st wave. Complications were almost unknown during this out-
eak. A few cases which developed broncho-pneumonia or
emorrhagic oedema of the lungs towards the end of the wave
nt up the case mortality. In all these characters, the first wave
sely resembled the outbreak of 1890, except that in 1890 the
ath-rate was greatest amongst the middle-aged and elderly,
ile in 1918 the chief sufferers were amongst the "young adult"
oups.

The Second Wave.—Towards the end of September or early in October, the second wave suddenly gathered force and swept over the world. St. Helena is said to have escaped. Mauritius, too, had a reprieve; and the quarantine measures applied by Australia were successful for the moment but this fatal pandemic spread throughout Europe, America, Asia and Africa.

The upward curve of morbidity was almost precisely similar to that of the summer and the maximum was reached as quickly as in the previous wave, but the fall was much slower and less regular. The outstanding difference between the two waves was the marked tendency to pulmonary complications and the high death-rate of the second. The singularly uniform syndrome of the summer epidemic gave place, in the autumn, to several varieties of clinical picture depending on varying combinations of several factors, amongst which might be reckoned the virulence of the microbic invader, the resistance of the patient, the nature of the bacterial flora of his respiratory tract, and environmental conditions such as occupation, wages and housing. As a rule, the attack was ushered in by the catarrhal and pyrexial symptoms noted in May and June. In many cases, especially where circumstances permitted of immediate rest and treatment, the disease took a favourable course towards recovery, although prostration was clearly always a more marked feature than in the summer. In others, the early pyrexial catarrh was sometimes followed by intense toxaemia leading so rapidly to a fatal issue that there was no time for pulmonary complications to develop. But frequently the lungs became severely affected and the patient passed into a state of anoxaemia recalling that due to exposure to the "pulmonary irritants" of gas warfare.

But there was a formidable difference between the two conditions. While the "phosgene" patient had to deal with a sterile exudate, evoked by a chemical irritant and capable of rapid absorption if vitality was maintained, the lungs of the influenza patient were charged with an exudate evoked by a living virus which had already overcome tissue resistance and could offer to "secondary invaders" conditions of symbiosis favourable to their growth. Here lay the danger. The virus of influenza could open, as it were, the door to the *streptococci*, *pneumococci*, *staphylococci* and other organisms normally held within safe numerical limits upon the respiratory mucous membrane. The *post-mortem* appearances, while tending to have certain basal characters in common, varied considerably with the nature of the "secondary invaders" and other factors. In nearly all cases, there was a haemorrhagic tendency not often seen in other acute lung affections; and this sometimes amounted to a haemorrhagic oedema involving the greater part of both lungs. "Wet lungs," "dripping lungs," were expressions frequently heard in the *post-mortem* room. Areas suggesting haemorrhagic infarcts with their bases extending under the pleura were often noticed. The cut surface of the lungs showed, as a rule, peribronchiolitis and patches of broncho-pneumonia with a general state of oedema throughout the parenchyma of the lung; or a whole lobe might give the appearance of red, or in older cases, grey hepatisation.[1] The third wave had no distinctive characters. It resembled the first wave rather than the second, though pulmonary complications and fatal cases were fairly numerous.

Etiology.—As to the causative organism of influenza we remain, even now, still in doubt. The view that the *Bacillus influenzae* (Pfeiffer) was the cause of the disease, received little support from the new investigations carried out from 1918 onwards. This work was directed, for the most part, to the search for a "filter-passing virus." During the second wave of 1918, the researches of C. Nicholle and Lebailly in the French War Zone, of H. G. Gibson, F. B. Bowman and J. I. Connor at Abbeville, and of J. A. Wilson at Étaples, in the zone of the British Armies in France, afforded highly significant evidence in favour of a filterable virus, although the restrictions imposed upon bacteriological work by war conditions and the transitory nature of the epidemic rendered conclusive findings impossible.

---

[1] For a detailed account of the *post-mortem* appearances, together with their morbid histology, see the article by Maj. Tytler, R.A.M.C., in *Special Report Series No. 36*, Medical Research Council (1919).

In 1919, an investigation was undertaken by Zamanouchi, Sakakami and Iwashrima, in which the filtered and unfiltered emulsions of sputum from 43 cases of influenza were injected into the throats and noses of 24 healthy volunteers, six of whom had recently suffered from influenza. Of the 18 previously uninfected persons, all developed influenza after an interval of two or three days, but the six who had had the disease remained in good health. Similar results were obtained with the filtered blood of patients. At the same time, the spraying of cultures of Pfeiffer's bacillus, sometimes "pure," sometimes mixed with other respiratory bacteria, into the throats of 14 healthy persons failed to lead to illness of any kind.

P. K. Olitsky and F. L. Gates in the Laboratories of the Rockefeller Institute for Medical Research were able to approach the subject with much more deliberation and with a much better equipment than was available in France; and their results are proportionally more convincing. Like Gibson and his coworkers, they produced in rabbits a condition closely resembling human influenza by means of filtered or unfiltered nasal secretions taken from human patients during the earliest stages of the attack. They provided independent confirmation of the discovery of Gibson and Bowman that "cultures" in Noegouchi Medium were capable of transmitting the disease to animals, and showed that the anaerobic and filterable organism thus cultivated retained its activity after long exposure to glycerine and possessed antigenic properties. To the minute organism isolated by them in the course of this inquiry, they gave the name of *Bacterium pneumosintes* (πνεύμων lung: and σίντης injurer), "since a striking feature of its effect in rabbits is to diminish the resistance of the lungs to the action of ordinary pathogenic bacteria."

Their work received speedy confirmation at the hands of Dr. M. H. Gordon, C.M.G., F.R.S., in the course of an influenzal outbreak among the Nursing Staff of St. Bartholomew's Hospital, London, in 1922. Still further support for a "filter-passer" as the virus of influenza was later provided by Sir Spenser Lister in South Africa. These independent inquiries, leading to similar findings in America, England and South Africa, go far to establish the "case" for a filterable virus as the causative agent of influenza; but caution is still needed in drawing final conclusions until a more precise knowledge is available as to "filter-passers" in general (*see* FILTER-PASSING MICROBES).

Epidemiology.—In the absence of final knowledge as to the causative agent, many points of fundamental importance still remain obscure. Was the pandemic of 1918–9 a sudden awakening to virulence of some germ already widely distributed in western Europe or was it a "new arrival" operating in "virgin soil"? Then the question arises: "Where could such a germ come from?" If previous pandemics were due to the same agent, no doubt, somewhere, from one pandemic to another, some human individual or chain of individuals carried on the virus until the time was ripe for a fresh outbreak.

The first wave coincided with the arrival of the first drafts of American troops in Europe, who must have brought into common circulation pathogenic strains that had long remained dormant in isolated and relatively immunised communities. The crowded troopships afforded just the incubation places that would permit of the maturation of such an infection; and Europe, with its crowded concentration areas and billets, offered an unequalled opportunity for its spread. The last influenzal pandemic had occurred just 28 years before. There might be a few scattered "carriers" and perhaps some residual immunity among the middle-aged and the elderly; but the adolescents and the young adults would in 1918 be "virgin soil." It was just these lower age-groups that suffered most.

How, then, explain the second wave with its greater severity? —and the third? Surely, if immunity played a part, these waves should have been much less extensive, much more benign, and confined to those persons who had previously escaped. These are good, but not final, arguments. The passage of the first wave may have left behind it a virus of exalted virulence, many "carriers" and many "allergic" subjects whose behaviour to reinfection might betray the phenomena of hypersensitivene of the respiratory surfaces and a tendency to inflammatory ex dates on contact with the air-borne virus. Under such cond tions a fresh outbreak would be specially likely to arise in th fall of the year, a period of rapid fluctuations of temperatu when the chill evenings drive men into the warmth and close con tact of crowded dug-outs, shelters and billets.

It is impossible to believe that the so-called "influenza" t which deaths were attributed every year between 1892 and 191 was the same disease as the fulminating pandemic that followed Apart from the extreme contrast in invasive power, the distr bution of "influenza" mortality by age-groups[1] emphasises th essential difference between, let us say, the death-rates for 191 and 1918, the one having a preponderating death-rate among the old, the other, amongst the young. Such differences can har ly leap into existence within a few months. The known facts o increase and diminution of bacterial virulence do not support th idea that such a vast alteration is probable or even possible i so short a time.

Acquired Immunity.—Evidence that morbidity and mortalit were less marked, in the second wave, amongst those who ha been attacked in the first, when thoroughly analysed[2] was foun to indicate that "these data show a considerable immunisin power in the summer attacks and we conclude, although wit natural hesitation, that it is probable, on the average, that a appreciable degree of active immunity was attained by those wh passed through an attack in its first and mildest manifestations.

The evidences for immunity are of varying efficiency in di ferent places, and the populations of many areas show no tend ency at all to acquire resistance to infection as judged by comparison between the behaviour of those attacked and thos missed by the first wave when confronted by the second.

We believe these data to be unsound as a basis for comparison. It is highly probable that many persons were infected during th summer and yet failed to show appreciable illness. The vas difference that may exist between the numbers *infected* and th numbers *affected* by a bacterial invasion can be judged from wha we know of the meningococcus and the diphtheria bacillus. An yet these latent infections may confer active immunity, as we know from the "Schick Reaction" in the case of diphtheria and from many other examples as well. The mere fact of a previ ous "attack" is not a safe guide in classifying populations fo inquiry as to their relative immunities. The best evidence of the acquisition of immunity is to be found in the phenomena o natural recovery of the individual and of the disappearance of pandemic waves from the community. The fact that these groups of pandemics are separated by long and fairly regula intervals, as a rule about 20 years, is not without significance in this connection, since at least this period might be necessary to reduce the residual "immune population" from the last pandemic to an ineffective number.

Artificial Immunity.—No vaccine can be entirely satisfactory unless it is known to contain the virus or germ of the disease in question. The vaccine issued by the War Office and afterwards by the Ministry of Health was confessedly of a provisional nature since the causative agent was still uncertain. Its formula was as follows:—

	Per cu. cm. of vaccin
Bacilli influenzae (Pfeiffer)	400,000,000
Pneumococci	200,000,000
Streptococci	60,000,000

Unless Pfeiffer's bacillus be accepted as the causative agent, this vaccine must be described as consisting entirely of the "secondary invaders." As such, its issue was entirely justifiable and its effects were such as might be expected: satisfactory in diminishing complications and mortality but practically *nil* in preventing the disease. Vaccine, then, cannot, as a prophylactic help us much at present; nor can we, in the light of recent experience, hope for great results from general measures of hygiene.

GLIS, ELSIE MAUD (1864–1917), British physician and on, was born at Naini Tal, India, Aug. 16 1864. After a iood spent in India and Australia, in 1878 she settled with amily in Edinburgh. She studied at the school of medicine omen in Edinburgh and at St. Margaret's College, Glasgow, iating M.B. and C.M. In 1895 she took up private practice linburgh and was instrumental in establishing a second l of medicine for women in that city. Dr. Inglis became one of iost prominent suffrage workers in Scotland. In Aug. 1914, ed by her, a special committee of the Scottish Federa- of Women's Suffrage Societies, aided by the National Union omen's Suffrage Societies, undertook the organisation of the ish Women's hospitals for foreign service, and raised ooo. She first went to Serbia in April 1915 to relieve Dr. u at Kragujevac. In Nov., during the enemy invasion rbia, Dr. Inglis and a few others remained behind until 1916 as prisoners of the enemy to care for the Serbian ded. In Aug. 1916 she took a unit to the Dobruja for service the newly formed Serbian division attached to the Russian . She died at Newcastle-on-Tyne Nov. 27 1917. See Lady ces Balfour: *Dr. Elsie Inglis* (1918).

ITIATIVE (*see* 23.1).—The initiative is one of the two forms rect popular legislation, the other being the referendum. zerland is the classic land of both initiative and referendum. ite as 1910 its experience with these devices of popular was much more extensive than that of the rest of the d combined.

ie Swiss example was copied first in the United States where nitiative was introduced by South Dakota as early as 1898. equently nearly half the states in the American Union have ited one or both forms of direct legislation. Most of these nonwealths are west of the Mississippi, but of more recent s five eastern states, among them Ohio and Massachusetts, accepted the initiative. Twelve states provide for official tins of information, commonly known as "publicity pam- ts," containing texts of laws to be voted upon with argu- ts pro and con, which are distributed before the vote to all ors in the state. As a common feature of the commission commission-manager forms of government now in effect in e 400 cities throughout the United States, direct legislative hods have also been made widely applicable to local charters ordinances.

ollowing American developments in this field the next great in the extension of the initiative was taken after the World by the constitution makers of several revolutionised or new es of Europe. In varying forms this device has been established by the constitutions both of the German Reich (1919) and of the Prussian State; also by the constitutions of Austria, Estonia and the Free City of Danzig—all the latter dating from the year 1920. The constitution of the Irish Free State (1922) provides specifically for the referendum; it authorises also the Irish Parliament to establish the initiative by law, expressly stipulating that a petition signed by 50,000 voters shall be sufficient to start action either upon a constitutional amendment or upon an ordinary law.

Swiss Experience.—Up to 1908 the Federal initiative in Switzerland was employed, generally without success, to promote radical measures. Since that year it has scored a number of constructive achievements, among them the amendments providing for Federal regulation of water-power (1908) for election of the National Council by proportional representation (1918) and for the submission of treaties concluded for periods of 15 years or more to popular vote upon the same terms as ordinary legislation, *i.e.*, petition signed by 30,000 voters or demand of eight cantons (1921). In 1922 a drastic capital levy initiative proposal brought forward by the Socialists was defeated by a popular vote of 736,652 to 109,702 and by all cantons against none. Experience with direct legislation under the new constitutions of Europe has been too brief to warrant conclusions. In Germany where a petition requires 3,000,000 signatures, the initative has been used but once (June 20, 1926) but without success. (*See* GERMANY.)

American Experience.—In the United States the initiative has been freely employed, so freely indeed that in connection with referendum measures the ballots of certain states have been at times greatly overcrowded. The initiative has been repeatedly used by small reform groups to advertise their projects. In Oregon it was employed successfully to pass a so-called compulsory school attendance law (1922), obviously inspired by hostility to parochial schools, which was held by the Supreme Court of the United States (1925) to be unconstitutional. Coincident with the extension of direct legislation there has developed a tendency to exclude from its operation certain classes of measures, particularly finance bills and Acts of an urgent character. Thus in the United States the Massachusetts initiative and referendum amendment (1917) bristles with restrictions excluding from popular vote religious issues, judicial tenure and powers, local legislation, specific appropriations, anti-Prohibition measures and various personal and property rights. In spite of much criticism, however, direct legislation is generally sustained by popular opinion in those American states which have provided for its establishment.

INLAND WATER TRANSPORT.—Transport by navigable waterways in the last years before the War reached very high figures indeed. In 1875, 10,400,000 tons were carried by water in Germany; in 1910, 64,750,000 tons. The bulk of the increase was on the large rivers and canals; the less important waterways showed no advance, and in some cases actually a falling-off. In the Netherlands and Belgium the ports of Rotterdam, Amsterdam and Antwerp benefited by the great development of Rhenish industry in Germany, the Rhine being admirably suited for carrying both ores and coal. In the riparian states of the Danube the movement of industrial products downstream and of cereals and oil upstream has produced a similar increase in water-borne traffic.

This general development of traffic by navigable waterways everywhere led to the undertaking of important hydraulic work in the construction of new waterways and the improvement of existing ones. Steps were taken to regulate and canalise rivers; canals were cut to link up important rivers; existing canals were enlarged so as to be navigable by vessels of larger tonnage; and gradually a whole network of navigable waterways has spread over central and western Europe. The total length of the navigable waterways in France before the War was more than 11,000 kilometres. In Germany it exceeded 10,000. The capacity of the German waterways was on the whole greater than that of the French, since many of the canals in France were navigable only for vessels of 300 tons or less.

Effects of the War.—The World War interrupted the development of inland navigation, and its termination was followed by a transport crisis due mainly to the disorganisation of the railways through the wear and tear of rolling stock and rails, and the destruction of considerable portions of tracks and railway installations. Normal currents of traffic had to be re-established, and demobilisation raised a difficult transport problem. Even the full use of navigable waterways was insufficient to meet immediate requirements. The destruction of many waterways with their works (bridges, locks, etc.) and of many vessels used in inland navigation, helped to make matters more difficult. But repairs were fairly quickly effected and in 1920–1, indeed, when the railway crisis was still acute in consequence of a shortage of rolling stock, there was a surplus of inland navigation tonnage owing to the considerable increase in freights due to the rise in the cost of living. Governments avoided or took measures to prevent any great increase in railway rates until the existence of large deficits showed that it was necessary to adapt rates to the increased expenditure. Navigation, on the other hand, being entirely in the hands of private individuals, had to adapt itself immediately to the increased working expenses.

Furthermore, governments in some cases used the railways to establish new currents of transport, which had become desirable in consequence of altered frontiers, or to help national seaports to compete with foreign seaports. Sometimes, too, by instituting competitive rates on the railways, governments tried to obtain larger receipts which would enable them to meet the deficit of the railway budget. Another factor which unfavourably affected the financial results of inland navigation concerns was the absence of proper upkeep of the waterways during the years 1914–8. Rivers which require constant attention suffered to a large extent in this respect, and it proved impossible to employ the river-craft to their full capacity.

But the main cause of the bad conditions of inland navigation after the War was that financial and economic crises, the instability of the exchanges, and general impoverishment did not allow the resumption of transport which had been expected.

In France the total amount of goods carried on rivers and canals, which was 41,896,754 tons in 1913, was only 21,500,000 in 1920. In 1924 the figure had risen to 36,758,000 tons, traffic assuming large dimensions in the north of France, as well as in respect of goods and vessels coming from and proceeding to the port of Strasbourg. The following figures for the port of Paris may be noted: in 1913, 4,786,649 tons were loaded and 11,709,824 tons unloaded; the figures for 1924 were respectively 2,769,166 tons and 10,221,228 tons.

The total traffic for the Rhine, which in 1913 was 54,562,574 tons, had fallen in 1918 to 25,608,609 tons and by 1923 as low as 16,608,609 tons. In that year—a quite abnormal one certainly, owing to the Ruhr occupation—traffic through the port of Duisburg-Ruhrort, which in 1913 was about 26,000,000 tons, and which was still 14,000,000 tons in 1922, fell to 3,980,412 tons.

The situation is exactly the same as regards traffic across the German-Dutch frontier near Lobith. From over 37,000,000 tons in 1913 the figures fell in 1918 to scarcely 5,000,000 tons, but by 1924 had risen again to 23,000,000.

On the Danube in 1911 the total movement of goods was 6,802,639 tons and in 1924, 3,757,010 tons. The year 1925, however, showed a considerable increase in traffic.

The same effects are observable in Russia, although, in this case, it is necessary to take account of the great disturbance caused by the Civil War, the Bolshevist régime and the famine which ravaged the Volga basin in 1921. In 1913 the total weight of goods carried by water amounted to 2,281,900,000 pouds (approx. 38,000,000 tons), of which corn accounted for 229,000,000 pouds. In 1920 the total figure had fallen to 665,500,000 pouds. The corresponding figure for corn is negligible. For 1925 the total figure was, according to official statements, 1,405,200,000 pouds.

Nevertheless, general improvement took place. Take as an example the port of Rotterdam. The total amount of goods transported on barges in 1924 was 19,000,000 tons, whereas in 1923 the figure was only 8,000,000 tons. Even allowing for the effects of the Ruhr occupation, this denotes a very considerable increase.

Extension of Waterways.—The improvement of navigable waterways was resumed after the War and, although many big schemes can hardly be expected to materialise, it is none the less true that a large number of far-reaching plans are already in course of being realised, or are ripe for execution.

Rhône-Rhine Navigation.—The navigable waterway which the canalisation of the Rhône would establish from Marseilles through Lyons and Geneva (if the French and Swiss governments agreed
about the régime for the Lake of Geneva), might be of first-
importance for traffic to Switzerland, and the eventual continua
of this waterway through Switzerland by the canal known as En
roches (a scheme warmly supported by the Swiss Assn. for Rh
Rhine Navigation), would increase its importance. This schem
a navigable waterway between the Rhône and the Rhine thro
Switzerland seems still immature.

Rhine Navigation.—The second large scheme prepared by
French Govt. is for the great Alsace Canal between Huningue
Strasbourg. This canal, which will serve both for navigation and
supply of water-power, is to follow a course nearly parallel to
Rhine over a distance of about 114 kilometres. The plan invo
the erection of a weir across the Rhine bed. Further, eight po
stations will be constructed on the canal and two locks place
each station. The dimensions of this waterway would allow ba
of 1,200 tons, normal type on the Upper Rhine above Mannh
The scheme for this canal required the approval of the Central C
mission for Rhine Navigation. After giving its consent to the
struction of the first reach of the canal in 1922, the commissio
April 1925 approved the scheme for the sèven other reaches sub
to certain conditions.

Switzerland has prepared a scheme for the regulation of the R
between Strasbourg and Basel. This scheme has also been condit
ally approved by the Central Rhine Commission, and the work
therefore shortly be put in hand (*see* RHINE).

Communication with Antwerp.—A clause in the Treaty of Versa
provides for the possible construction of a deep-draught canal f
Antwerp to the Meuse and the Rhine, ending in the neighbourh
of Ruhrort. The early execution of this scheme is unlikely, especi
as the plan for the Antwerp-Moerdijk canal, which is provided
in the new Dutch-Belgian Treaty, will secure for Antwerp ad
tages at least equal to those offered by the Antwerp-Ruhrort c
and at an infinitely smaller cost. No technical details are yet kn
of the Antwerp-Moerdijk canal scheme, but the waterway
created will be made navigable for the large Rhine barges, that
say, for vessels up to 3,000 tons.

Meuse Canalisation.—In the Netherlands the most import
scheme now being carried out is the canalisation of the Meuse
Dutch territory, which further involves a junction canal betw
the Meuse and the Waal and the Juliana canal from Maasbr
southwards, the latter intended to link up the mining centre with
navigable waterways of the country. The canalised Meuse wil
navigable for boats of 2,000 tons. Locks 260 metres long will be
to take a tug and two barges of 2,000 tons each. The Meuse-W
canal will be navigable for boats of the same tonnage.

Completion of Rhine-Vistula System.—In Germany two l
schemes are being carried out. The Mittelland canal, which
connect Hanover with the Elbe near Magdeburg, will establish
uninterrupted navigable waterway between the Rhine and
Vistula. This canal will form the last section of the waterway be
with the construction of the Dortmund-Ems canal between
and 1899, followed by the Rhine-Herne canal, opened in 1914,
the Bevergern-Misburg canal constructed during the War.
last-mentioned canal, which is 172 km. long, is without locks.
total length without locks, including certain parts of adjacent can
is no less than 213 kilometres. The Mittelland canal will be nav
ble for boats of 1,000 tons. It will cross the Elbe by a bridge,
plans for which have been submitted for the approval of the In
national Elbe Commission.

Rhine-Main-Danube Connection.—The second important sch
in process of execution is the junction between the Rhine, the M
and the Danube. The idea of linking up the Rhine and the Dan
is a very old one. Charlemagne conceived the idea of constructi
canal, traces of which can still be seen. The Ludwig canal, opene
1846, was only navigable by small boats up to 120 tons and
never been much used. It is anticipated that the area tapped
the Rhine-Main-Danube navigable waterway will exceed that
any other European river and canal system. The scheme invol
the canalisation of the Main, the construction of lateral canals
of a junction canal between the Main and the Danube, joining
with the latter near Kelheim. It also necessitates the regulatio
the Danube between Regensburg and Hofkirchen, and betwe
Passau and the frontier and in addition its canalisation over
stretch between Hofkirchen and Passau, that is to say, in the
varian Kachlet. The waterway will be navigable for canal barges
1,200 tons and for Rhine barges up to 1,500 tons. The scheme
provides for the utilisation of hydraulic power; in fact, it is the p
duction of electric power that has made the scheme practicable.

Other German Schemes.—Among the other plans for the constr
tion of canals in Germany, such as the Hansa canal, the canal fr
the Weser to the Main, the Kuesten-Kanal and the junction ca
between Neckar and Danube, only the last deserves serious co
sideration at present. The canalisation of the Neckar might b
considerable value for the development of navigation and for
port of Mannheim. At one time it seemed that, mainly for politi
reasons, opinion in Germany was in favour of constructing
Weser-Main canal (the Weser being the only important river wh
has escaped internationalisation), in order to direct part of
traffic from the Danube to Bremen, after the construction of t
Main-Danube canal. The Weser could also carry some of the tra

ılly carried by the Rhine and the Elbe. But the changed polit-
tuation makes it improbable that this scheme will be put into
at any early date.

ian Waterways.—In Italy a canal has been constructed from
o to Brondolo on the Lagoon of Venice. A canal is also in
of construction from Milan to the confluence of the Adda and
, whereby Milan will be linked by waterway to Venice.

choslovakian Waterways.—In Czechoslovakia, besides canalisa-
vork on the Elbe and the Moldau and the regulation of the
be, the Govt. has carefully considered two canal schemes, an
Danube canal and an Elbe-Oder canal navigable for vessels of
tons. The length of the Elbe-Danube Canal would be about
lometres. Its course would follow as far as possible the line of
ıost important towns. Financial considerations are retarding
ecution of these schemes.

ish Waterways.—Polish plans include schemes for several canals
, navigable by boats of 1,000 tons, would constitute, together
he regulated parts of the Vistula, a complete system of naviga-
ıterways across Poland. This plan would involve the construc-
f a canal which would start from Kattowitz in Upper Silesia,
northwards and join the Vistula either at the mouth of the
or near Thorn, making use in several of its sectors of existing
ıble waterways as, for example, Lake Goplo. Another canal
extend from Posen via Konin and Warsaw to Pinsk, taking
art of the Warte and of the canalised Bug, together with the
structed King's canal between Brzesc and Pinsk. The latter
way would have to be continued from Pinsk to the Russian
er in order to link up with the great navigable system of
ı.

Russian System.—The Russian rivers which are naturally
ıble have suffered but little from the lack of upkeep in the
of the last 10 years. The proposal to construct the Rostov
to unite the Volga and the Don may be carried into effect,
h there are great technical difficulties in the way of this scheme.
mpletion would reduce the cost of transport of oil from Baku,
om Astrakhan, corn from the valleys of the Volga and the
, coal from the Donetz and merchandise from Persia. The
tance of the proposed canal is obvious, as the immense system
Volga, which is navigable for more than 16,000 km., will thus
ked up with the Black Sea, and the Baltic, Black and Caspian
vill be connected by navigable waterways. There is already a
e between Leningrad via the Mariinsky system and the Volga
rakhan and thence to the Persian port of Enzeli. The immense
ory of Russia may become of capital importance in the future
the point of view of inland waterway communications. The
ı of waterways is more than 200,000 km. in length, of which at
t some 40,000 are navigable. The Asiatic Russian system
he Ob-Yenesei mouths to Central Asia and Lake Baikal lies
e the scope of this article.

nomic Considerations.—Economic considerations will natu-
play an extremely important part in any decisions taken in
to the improvement of existing waterways or the con-
ion of new ones. The question will inevitably arise whether
way would not prove more serviceable than a waterway.
reference will clearly go to whichever mode of transport is
er. In comparing the advantages of waterways and rail-
we must distinguish between rivers and canals; and we
further discriminate between canals built across flat
ry and those constructed across land where there are
ed differences in level.

ers not naturally navigable may generally be rendered nav-
by regulation works, such as spur dikes or longitudinal
or by canalisation works such as the construction of dams
the bed of the river and locks to enable boats to pass.
orming of large reservoirs in the upper courses of water-
belonging to the basin of a large river may also constitute
cellent means of improving navigability by regulating the
f water. In this way a greater minimum depth is obtained
he period of navigability during the year is lengthened.

a rule the cost of building a railway having the same
ing capacity as a river is appreciably higher than the cost
king the river sufficiently navigable. Moreover, the cost
er-craft having a given loading capacity is less than that of
y rolling stock having the same capacity. Further, the
ge power of a locomotive is only a small fraction of that of a
This argument remains true even if a proper use of a water-
nvolves the execution of improvement works. Moreover,
conomic development of the area served by the river leads
considerable increase in passenger and parcels traffic, for
the railway is necessarily more suitable than the water-
so that we always find railway lines alongside the river, connecting up the various important centres situated thereon. The argument that a river can compete with a railway holds good even if the traffic does not, strictly speaking, consist of heavy goods, such as ores or coal. The Danube is a case in point; before the War the volume of traffic on that river amounted to nearly 7,000,000 tons.

The case is different, however, if it is an artificial navigable waterway, *i.e.*, a canal, which has to be built. As a rule such a work is not justified from the economic point of view unless the prospective traffic in heavy goods (ores, coal, building material, cereals, and certain other agricultural products) is to amount to several million tons per annum. In order to determine the cost price of transport by canal we have to allow for possible profits and advantages derived from the exploitation of hydraulic power, and accordingly we have to make a distinction between a canal crossing flat country and a canal built in mountainous districts. Many projects for artificial waterways have been rendered feasible by the utilisation of water power. Wherever the configuration of the ground has permitted, recent schemes have combined the construction of a navigable waterway with the exploitation of hydro-electric power. The question therefore whether, in any given case, it is preferable from the economic point of view to construct a canal rather than a railway cannot be answered so readily as when the alternatives are a railway and a river; the answer depends upon a very large number of factors.

International Rivers.—A special category of waterways is constituted by those which come under the scope of the Convention on the Régime of Navigable Waterways of International Concern[1] concluded at Barcelona on April 20 1921. The criteria adopted at Barcelona were the fact of crossing or separating a number of countries, and natural navigability to and from the sea. In addition to the obligations which devolve upon riparian states, particularly in connection with works of upkeep, the Barcelona Convention lays down the principle of freedom of navigation and equality of treatment for all flags.

The objection has sometimes been raised that two different ideas have been confused, namely, the territorial idea and the idea of international traffic. It is clear that if it is in the interest of international traffic that there should be no flag discrimination, this principle applies wherever international navigation is carried on, independently of the fact whether the navigable waterway crosses or separates several states or not.

On the other hand it is only natural that, as regards international rivers, there was a desire to impose certain strict obligations on riparian states in connection with the hydraulic works to be carried out; these obligations, however, should rather be regarded as reciprocal obligations between riparian states. It would seem not impossible by drawing a clear distinction between the territorial idea and the idea of international traffic, to lay down, for all navigable waterways on which international traffic can be carried on, contractual provisions similar to those which have been drawn up for maritime ports.

---

[1] In the application of the statute, the following are declared to be navigable waterways of international concern:

1. All parts which are naturally navigable to and from the sea of a waterway which in its course, naturally navigable to and from the sea, separates or traverses different states, and also any part of any other waterway naturally navigable to and from the sea, which connects with the sea a waterway naturally navigable which separates or traverses different states.

It is understood that:

(*a*) Trans-shipment from one vessel to another is not excluded by the words "navigable to and from the sea";

(*b*) Any natural waterway or part of a natural waterway, is termed "naturally navigable" if now used for ordinary commercial navigation, or capable by reason of its natural conditions of being so used; by "ordinary commercial navigation" is to be understood navigation which, in view of the economic condition of the riparian countries, is commercial and normally practicable;

(*c*) Tributaries are to be considered as separate waterways;

(*d*) Lateral canals constructed in order to remedy the defects of a waterway included in the above definition are assimilated thereto.

(*e*) The different states separated or traversed by a navigable waterway of international concern, including its tributaries of international concern, are deemed to be "riparian states."

2. Waterways, or parts of waterways, whether natural or artificial, expressly declared to be placed under the régime of the General Convention regarding navigable waterways of international concern either in unilateral Acts of the states under whose sovereignty or authority these waterways or parts of waterways are situated, or in agreements made with the consent, in particular, of such states.

Inquiry into Existing Conditions.—In accordance with a resolution of the Economic Conference of Genoa, which was approved by the Council and Assembly of the League, the Organisation for Communications and Transit decided in 1924 to make inquiries of the various European governments concerned regarding the present situation of inland navigation in their respective territories. It also decided that the study of the complex problems which might be raised in connection with the great international rivers with many riparian states, should be entrusted to Mr. Walker D. Hines, United States Director of Transport during the War, who was appointed after the War as arbitrator in the allocation of river tonnage on certain international rivers. Accordingly Mr. Hines carried out an exhaustive study of the position of inland navigation on the Danube and also carefully examined the existing difficulties on the Rhine. It is hoped that Mr. Hines's reports on Danube and Rhine navigation as well as the results of the general inquiry will help to promote co-operation among the riparian states and to solve existing difficulties, in order that inland navigation may develop unhindered, and may occupy among the various means of communication a position which will enable it to play a great part in restoring economic stability and promoting the prosperity of the European nations. For the development of inland water transport in America *see* the articles Great Lakes and St. Lawrence and Mississippi River.

INOUYE, KAORU, Marquess (1835–1915), Japanese statesman (*see* 14.587), died Sept. 1 1915.

INSANITY (*see* 14.597, and Psychiatry; Psychoanalysis; Psychosis; Psychotherapy).—A change in the conception and in the handling of the facts characterises the present century. Instead of " Lunacy " and " Insanity " we speak to-day of mental disorders, of psychoses and psychoneuroses, viewed as problems of the adaptation of the individual to his environment.

During the World War a wide range of mental disorders had to be met by medical and military officers many of whom had never before concerned themselves with such problems. A new type of sympathy and sense of duty towards the victims of " war shock " laid the foundation for a more understanding interest in mental disorders in general, and aroused the demand for their effective management, not by mere relegation to official asylums, but by active therapeutic measures.

Definition.—" Insanity "—implying as a rule an incapacity to grasp the fact and nature of the existing sickness or disorder and a lack of responsibility for personal care and conduct, with possible neglect of or actual danger to self or others—is a contingency rather than the essence of many disorders, and cannot properly be studied and understood by limiting oneself to the " insane " as we find them in the centres of segregation which we call asylums, refuges, retreats or mental hospitals. The wider field of psychiatry (*q.v.*) now includes mental and behaviour problems outside as well as inside hospital walls, and experienced help, medicinal at times but also to a large extent taking the form of guidance in the problems of adaptation, has supplemented or replaced mere custody in institutions. Mental hygiene, administered through mental health boards and committees in the United States and in several European countries, offers constructive and preventive measures which are carried out largely in centres where physicians, psychologists and
workers collaborate in the work.

Advances in Etiology

Nationality and Race.—Interesting statistics on menta
orders in different nationalities making up the admissio
the Massachusetts hospital at Worcester, and to the New
state hospital at Blackwell Island suggest that national and
habits play an important part, the greatest differences lyi
the relative rôle of alcohol and syphilis and in the frequen
temperamental and psychoneurotic maladjustments.[1] The
admitted had 27·69% alcoholic psychoses and 37% largely
chogenic (temperament- and behaviour-determined) diso
while the Jews presented 0·32% alcoholic but 65% largely
chogenic disorders. Of the Irish only 7·59% showed paresis
a form of brain syphilis); of the Jews 14%; of the Germans
and of the negroes 29·41%.

Occupation.—The incidence of mental disorders in
occupations is dependent largely on the degree of exposu
harmful influences, and also on the temperamental factors
may determine the choice of a profession.[2]

Heredity.—The question of heredity is not as simple
appeared in 1911. While the dispositions are inherited, it
highly probable that additional factors, in the form of life-
riences, play a considerable rôle. The attempts to use Men
principles led to the conviction that affective disorders (m
depressive psychoses) follow a dominant, and schizophreni
orders a recessive type. The work of Mott and others ap
to show that these two conditions may follow a law of anti
tion according to which the mental symptoms develop
earlier age in succeeding generations of psychopathic
Lately, we meet with the assumption that at least two or
factors are needed to determine schizophrenic or manic-d
sive attacks, and geneticists like Jennings even tell us th
had best forget the theory of unit characters, in man, beca
the complexity of the facts to be considered. Eugenics (*q.v*
shown itself applicable in two ways, negatively in the ste
tion of the most obviously degenerate offspring of psycho
families, and positively in the training of the young to
healthy mating and sound sexual hygiene.

Infections.—The claims made with regard to the impor
of infection (14.598) and in the publications of a few surg
inclined psychiatrists have not been borne out under
scrutiny. Both the " agglutinines pointing to strepto
infections present in every case " of manic-depressive diso
and the claims of 80 to 90% recoveries after removal of
infections and of the colon, are largely discredited, part
the very material of those making the claims. In the face
the propaganda, the theory of autointoxication and much
more recent theory of endocrine disorders as etiological f
in mental disturbances are having an equally difficult time
the rigorous tribunal of strict hospital and field work and
tical tests. This does not mean that the " physical causes
being neglected or belittled. Much research has been
still being carried out on the morbid anatomy and biochem
of the psychoses and psychoneuroses. Mott has demonst
changes in the endocrine and particularly the generative g
of dementia praecox which in his view point to an " inbor
of vitality " in these patients. However, the old contro
between the physiogenic and the psychogenic theories as
causation of mental disorders is dying down before the
and more comprehensive conception of psychobiology, acc
to which the physical and mental make-up, the perso
tendencies and the determining factors and situations are
into account in the study and treatment of the patient.
cases constituting or akin to the dementia praecox or s
phrenia or parergasia group (described as katatonia and
phrenia in 14.606) have been shown to be much more re
understood and formulated for purposes of treatment
genetic-psychodynamic basis, with special attention to the

tances of the development of symptoms, than on the basis sweeping claim of inevitable deterioration due to " un- n " toxins or other causes, or on the theory of insufficiency docrine glands.

Special Types of Disorder

eble-mindedness.—The study of feeble-mindedness has been hed in various ways. The Binet-Simon tests and their fications furnish a dependable and comparative measure of ctual intelligence in terms of the " mental age " and the elligence quotient " or I.Q., *i.e.*, the mental age attained ed by the chronological age. One speaks of idiots where the nable age does not exceed three years, of imbeciles up to a -year level and of the higher grades of feeble-minded or ns between the eight and 15-year level. A retardation of less three years may lie within the range of error. The British commission of 1904 found that in groups of urban indus- and agricultural areas there was an average of ·32% of e-minded children and adults in the general population, of ·83% of feeble-minded among the children of school age, a higher percentage in towns than in country districts. A e-to-house survey of the children of school age of a well-cir- cribed industrial district of Baltimore, Md., was undertaken e Henry Phipps Psychiatric Clinic and published by Dr. C. ie Campbell.[1] Since then numerous surveys in the United s have corroborated the Baltimore results, which make it that about 2% of the children of a community should have al institutional training and some of these protection for an additional 6% should be in special classes for the re- d, and another 5% should have at least individual adapta- of the curriculum.

eater attention to the psychology of education has revealed act that children may fail to keep up to the standard of age for causes other than feeble-mindedness, and may pre- problems of maladjustment which had best be handled by sychiatrist. In England and Scotland the Mental Defi- y Act of 1913 has widened the range of defectives who may y be committed to institutions and makes provision for l imbeciles. Early diagnosis and anti-syphilitic treatment fect due to congenital syphilis is followed by improvement.

quired Mental Diseases.—A distinct advance is shown by act that the disease entity concept is giving way to the less atic concept of reaction-types. The specifications of the s of mental disease given in 14.597 are to-day largely replaced more genetic and constructive formulation and interpre- n of patients or individualities.

mentia Praecox.—An intermediate phase of rather opti- c simplification had introduced the concepts of maniac- essive (or affective) psychoses as essentially non-deteriorating, posed to the schizophrenic psychoses (also called dementia cox), which are apt to pass into deterioration, emotional ference and apathy. The manias and the melancholias d constitute the manic-depressive psychoses, while hebe- nia and katatonia are now included in schizophrenia. But these diagnoses, which aim largely at prognosis, have had eld to the recognition that one had best admit a number of tically important reaction-types of special working and ency of evolution, requiring further a specification of the al factors and the assets of the patient both for the deter- tion of the intrinsic nature and the formulation of a prog- s in each case.

ne simple notion of " one patient one disease," and a classi- ion under a one-name diagnosis indicating either a good or d outcome, cannot do justice to the multiplicity of points h demand consideration. A totally new conception of the titution of personality and its hereditary and individual ponents has supplemented the formerly dominant and almost sive conception of brain destruction by poisons and other cies. There is to-day less interest in special disease entities in the working of definite processes or developments vari- open to modification and adjustment.

The psychoanalytic contributions towards our knowledge of personality and towards the interpretation of mental symptoms, and the methods of treatment based on these theories, are variously evaluated, but have been stimulating in the study and utilisation of life-experiences (*see* PSYCHOANALYSIS and PSYCHOTHERAPY).

General Paralysis.—One of the most remarkable changes has occurred in our experience with the most fatal and disastrous form of mental disorder, general paralysis or paresis. There is no longer any doubt about its being due to an invasion of the brain by the spirochaete of syphilis. The disease may occur in children or adolescents through hereditary transmission of this organism, as well as in adults in whose cases symptoms may appear 10 or even more years after acquired syphilitic infection. But, far from being a uniformly fatal disease, it has now been found to yield to treatment. Early diagnosis, assisted by the application of the Wassermann test to the cerebrospinal fluid and not only the blood serum, and therapeutic infection with malaria (*q.v.*) or other recurrent fevers which appear to be incompatible with syphilis of the nervous system, enable as many as 40% of patients to enjoy a prolonged remission from their symptoms or to obtain a complete cure.

Commitment or Certification

It is unfortunate that there will probably always be a group of patients or phases of illness that lie between the two extremes of (1) voluntary co-operation and (2) forcible treatment. While there is a growing desire to extend facilities for treatment on a voluntary basis, it frequently happens that delay in dealing with an unwilling patient involves risks when suicidal or homicidal impulses are present. Following the lead of the continental clinics, hospitals have been opened in the United States and elsewhere for the study and treatment of early cases of mental disorders.

Most of the American institutions have an increasing number of " voluntary commitments " requiring in writing a " three days' notice of intention to leave," so that the physician may have the right to detain the patient pending the consideration of the best course to take in the further care. The commitments themselves in many states are left to a statement of two impartial physicians; in others they require court procedure or even jury trial, a method that is, however, more and more limited to habeas corpus actions, *i.e.*, a demand to show cause for the detention of a patient as a " committed " person.

The medico-legal problems of responsibility in mental disorders are still in an archaic state on account of the unfortunate fact that the rules of evidence which were invented for the normal are not favourable for the presentation of facts which have a psychiatric bearing. Another point of loose practice occurs in the United States in the proper disposal of patients who are declared " not guilty on account of insanity." A patient who gets into conflict with the laws should remain under safeguard until he shows evidence of insight and capacity for self-management.

The principles of equity procedure in use in juvenile courts promise beneficial reform and valuable experience based on a study of the individual delinquent according to psychiatric principles. The moral changes which are liable to follow an attack of epidemic encephalitis constitute a new and difficult problem (*see* ENCEPHALITIS LETHARGICA).

Statistics.—Statistics are notoriously inadequate where no continuous census and control of the population and its whereabouts is maintained. The number of " certified " insane patients under care in England and Wales was 131,557 on Jan. 1 1925, an increase of 1,217 over the number on Jan. 1 1924, but evidently less than the number before the War; 48·9% are males, 51·1% females. The recovery rate calculated on the direct admissions is given as 34·86%. The death-rate calculated on the daily average number of interned patients is 7·62%. The absence of any greater increase of numbers during and since the War is probably only apparent. The fifth report of the British Lunacy and Mental Deficiency Board of Control (1919) brought out a ratio of 208 (instead of the usual 76) cases of death to each

---

[1] *Mental Hygiene*, 1917, i., pp. 96–147.

1,000 of the interned insane and defective population, owing to a temporary increase of tuberculosis, diarrhoea and dysentery, typhoid fever, etc. The lack of fresh milk and fats and the disorganising of the nursing through the War must have been largely responsible.

Effects of Prohibition.—Considerable interest adheres to the question of the effect of prohibition in the alcoholic mental disorders. Wherever the alcohol traffic has been brought under control the reduction of "alcoholic insanity" has been striking. Where propaganda against prohibition has been most active, a moderate return of the old conditions has been noticeable. The experiment is too short and too imperfectly carried out to furnish an answer to the many questions arising.

INSECT BITES AND STINGS.—Insects may be the cause of disease or of morbid conditions in man in several different ways: (1) by living *on* his skin or hair, as in the case of three varieties of pediculi or lice (the head-louse, the body-louse, the crab-louse); or *in* his skin, as with the itch-insect (though this is strictly not an insect at all but a spider-like parasite), or with the tropical chigger, jigger or sand flea; (2) by depositing their eggs on the skin or mucous membrane, or on wounds, whence the larvae find their way below the surface, usually by boring or burrowing, as is the case with several tropical flies; (3) by being the instrument of transferring a bacterial infection to man from some other animal, as is the case with the rat-flea in plague, or by taking part as host in the life-cycle of a spirochaete or a protozoon and passing the parasite on to man, as is done by certain mosquitoes in yellow fever or in malaria; (4) by the direct and immediate effects of their bite or sting. It is with this last method only that the present article is concerned.

In Great Britain, as in most other countries, such bites and stings are exceedingly common, the most frequent biting insects being the common flea, the bed-bug, gnats and mosquitoes, and the most frequent stinging insects being the wasp, the bee, the hornet and the ant. It should be realised, too, that the effects of the louse are due not merely to its presence, as mentioned above, but to its actual bite.

The consequences of these bites and stings are well known, very few persons escaping some personal experience thereof, though susceptibility varies widely in different persons. Local irritation may be extreme, and the skin lesion produced may vary from a small reddened or erythematous patch or a tiny papule, to large urticarial or nettle-rash wheals, or even to a spreading cellulitis or inflammation of the tissues under the skin. These effects, though giving rise to intense discomfort, are rarely serious and usually pass off completely in a few hours or at most a day or two. Occasionally, however, dangerous developments occur.

The conditions most likely to lead to such developments are: (1) a very large number of stings, as when a swarm of angry bees settles on the body; (2) the lesion being on a mucous surface such as the tongue, the palate or the pharynx; (3) the supervention of some local complication such as erysipelatous or other streptococcal infection, or the direct transmission of some form of septic poisoning as by the bite of a fly which has been feeding on putrid material. In all such cases skilled surgical aid should at once be sought, as in extreme instances death has occasionally resulted and urgent measures may be necessary to deal with the situation.

Treatment.—The poison injected with an insect sting is, at least in many species, formed by a mixture of the secretions of two glands, one of which is acid (formic acid) and the other of which is alkaline. In most cases the acid predominates; hence weak alkaline solutions (soda or ammonia) are commonly effective in allaying the irritation. In some cases, however, especially, it is said, with the sting of some wasps, the alkaline element is predominant and in such instances a weak acid lotion (s
diluted vinegar) gives most relief. Other local application
effective character are alcohol, spirits of camphor, a solu
menthol or of permanganate of potash, a dilute solution
bolic acid, or even slices of the homely onion. In every ca
sting itself, if it remains in the skin, should be carefully ren

As preventive measures when insects are prevalent, car
menthol, lavender and oil of eucalyptus appear to have
virtue; and skilful and assiduous campaigns against flies
quitoes and wasps have of late added greatly to the ameni
a number of localities. *See* Bacteriology; Kala-Azar;
sitology.

(H. B.

INSTALMENT SELLING is in essence an extension of cre
retail purchasers, under some form of contract by whic
purchaser agrees to make partial payments at stated int
over a period of weeks, months or even years. It enables
sands of persons of limited means to acquire goods which
could not otherwise possess. The goods purchased are u
delivered after the payment of an initial deposit. This dep
sometimes merely a nominal sum; but frequently it amou
one-fourth or one-third of the price of the goods. The sel
tains title, or its legal equivalent, in the property until th
instalment is paid. This is accomplished by means of a c
mortgage, a conditional sales contract or a lease. The la
the method employed in Great Britain. In this article a r
of American developments will be given first.

I. IN THE UNITED STATES

The customary practice in the United States, wher
greatest development of instalment selling has occurr
described as follows: "When goods are bought on lease o
ditional sales contract, the title remains in the sellers
passes to the buyer only upon completion of the stip
payment. Under the lease plan, instalment payment
designated as 'rent.' (This form of instalment sellin
devised to conform to the laws of certain states.) But wh
chattel mortgage form is used, the title passes immediat
the buyer, and he gives the mortgage as security for paym
the balance due. Under any of these forms, the sellers m
possess the property if the conditions of the sales contra
not met by the buyer." (See *Instalment Merchandising,*
pilation No. 2, issued by the National Association of Credit

A tremendous expansion of instalment selling took place
years following the World War. The aggregate amou
instalment credit in force in the United States in 192
estimated to be close to $3,000,000,000; and this est
though based on insufficient data, is believed to be conser
in view of figures from the automobile industry showin
the total of automobile instalment paper then outsta
amounted to about $1,500,000,000. The grand total
instalment sales in the United States in 1925 was said
$5,000,000,000.

This extraordinary development was naturally viewed
alarm" by many conservative economists, merchant
bankers. Aside from what might be called moral objectio
chief criticism was that large-scale instalment buying mus
to unhealthy inflation and consequent disorganisati
business and finance. It is probable that severe business d
sion, with its accompanying unemployment and the
quent failure of workers to pay their instalments, would
disastrous to commercial firms that had failed to scr
carefully all credit applications. On the other hand, i
pointed out with much force that a high element of safe
taches to credit risks, each relatively small, which are
scattered throughout the community. The continued succ
many firms whose experience in instalment selling long
dates the latest boom, is proof that such a business may
soundly and as profitably conducted as any other.

Credit merchandising, in fact, had made a rapid g
before the beginning of the present century. It was first a
extensively to the sale of subscription books and wa
adopted by the piano and musical instrument business. I

applied to the sale of furniture, sewing-machines, jewellery,
toves; and thousands of these products have been paid for
ıe month by people with moderate, steady incomes. A very
proportion of instalment purchasers in the days before the
mobile were housewives who found it possible to make
l weekly or monthly payments out of their household
vances. Women have continued to exercise a large influence
his type of buying; and most articles thus obtained are
led upon by the whole family.

or a long period a certain social disapproval hung over
lment buying, particularly if the articles purchased were
ries. The purchase of homes by this method was, however,
ys regarded as praiseworthy, and most homes have been
ht on this plan. The boom of recent years, which has
st entirely removed the social stigma, began with the
tion of this method of selling on a large scale by the auto-
ile industry. When the United States entered the World
the time payment plan was utilised in the sale of huge
tities of Liberty bonds; and in the years that followed many
stment houses did a considerable volume of business selling
rities on deferred payments.

ıe volume of instalment sales of automobiles prior to 1916 was
st insignificant. Mass production of motor-cars closely
wed the development of finance companies to care for in-
nent business. Some of these finance companies were
nised outside of the automobile industry; others were
nised by large manufacturers. One of the most important
ıese was the General Motors Acceptance Corp., the volume
hose transactions grew from $10,000,000 in 1919 to nearly
,000,000 in 1925. Alfred P. Sloan, Jr., President of the
eral Motors Corp., stated that the losses, *i.e.*, retail charge-
luring this whole period were only .199 of 1% of the volume
etail business handled. (See *Nation's Business*, April 1926.)
. Hanch, General Manager of the National Assn. of Finance
ıpanies reported the results of an extensive survey completed
ng 1924 as showing a loss ratio of less than ⅛ of 1% on
egate new and used car business, amounting to $195,500,000.
American Bankers' Journal, April 1926.) It is seen there-
that losses in collection have been very small.

1926 there were more than 1,000 finance companies in the
ed States created for the purpose of handling automobile
hases. More than 75% of all motor vehicles sold during the
ious year were purchased on the instalment plan, the deposit
lly being about ⅓ of the price of the car, the balance being
led into 12 equal monthly payments.

nance corporations did two kinds of business, wholesale and
il; that is, they financed the purchase of cars by dealers from
ufacturers and the purchase by retail buyers from dealers.
he case of one low-priced car it was possible in 1925 to get
ession by making an initial payment of $12.40, and furnish-
wo endorsements to the note. This was followed by weekly
nents of $5 for a year, and at the end of the year a so-called
on-payment completed the transaction.

he fee of the finance company added to the purchase price
known as the time-price. After deducting the initial pay-
t from this time-price the remainder was generally divided
12 or more equal parts which constituted the monthly pay-
ts. Finance corporations usually calculated 15% per annum
rest on money actually outstanding, or from 6 to 8% on the
hase price. However, in some cases, where initial payments
very low, the subsequent payments extending over more
a year, and with no responsibility by the dealer for col-
ons, the final cost to the purchaser was as much as 30%
ve the cash price.

inance corporations secured their funds from the banks,
the particular function they served was to provide the
ssary machinery for investigation, supervision and collection
h the banks lacked. The different contract forms employed
already been described. It was customary for the purchaser
ıake out a note to the dealer for the amount remaining after
initial payment. The dealer passed on this note to the
ıce corporation, which paid him its face value minus its own fee. The dealer would either indorse the note, and thus assume responsibility for the payment of the monthly instalments, or he would agree to re-purchase the car in case of default by the purchaser. In some instances, however, the dealer assumed no responsibility: under this, the "no-recourse" plan, the charges of the finance company were higher. Under any plan the purchaser was usually required to insure the car against fire, theft and accident.

The prosperity of the automobile industry and the enormous sale of motor-cars in the United States was the direct outcome of instalment selling. This fact could not escape notice by manufacturers and dealers in other products. Consequently many articles never hitherto distributed by this means were offered on the time-payment plan; and many retail merchants who had once frowned on instalment selling either adopted the method gladly as a proved means of increasing business, or did so reluctantly to meet competition. In 1926, in the United States, it had become possible to purchase practically every article of consumption costing upwards of $25 (with the possible exception of food) on time payments.

This trend was well illustrated by the announcement in 1925 by a leading men's clothing store of Chicago of a so-called "budget system" under which garments might be purchased on a cash payment of ⅛ to ¼ of the purchase price, the remainder being payable in 10 weekly instalments. This shop had always conducted its business very conservatively, and had refrained from everything remotely related to instalment methods. Other retailers were inclined to be censorious, and clothing manufacturers were divided as to the merits of this innovation. But the management reported, after a short test, that it was successful, and some interesting facts were brought out. This store, like many others of the same class, maintained charge accounts for a large number of customers; and it is stated that payment on these accounts was often delayed as much as 60 or 90 days. But the customer who pays ¼ down and then 10% of the balance each week pays for his goods more quickly than he would under the ordinary charge-account.

One of the most conservative stores in New York has instituted an elaborate budget system for the sale of furniture. This budget system is essentially a plan for selling on time payments, but it has the advantage that the store first consults with the purchaser as to his income and furniture requirements, seeking by this means to minimise their risk and at the same time more accurately to satisfy the customer's needs. The consultation is of genuine benefit to the purchaser and often enables him to make a larger purchase with greater economy than if he bought haphazardly or piece by piece.

It is apparent that under these conditions credit can be extended to thousands of persons to whom a merchant would hesitate to grant an open charge account. Moreover, the purchaser doubtless feels it safer and more convenient to budget his payments by the week or month rather than to have the entire amount fall due within 30 days and then allow the account to remain unpaid for a longer period, through the acquiescence of the store-keeper, but with a consequent impairment of the purchaser's credit standing.

Although it has been customary to add a time-price or interest charge in making instalment sales, some merchants have endeavoured to maintain the same price for the cash customer as for the instalment customer. This practice probably cannot long continue. Certain stores have already taken advantage of the situation to advertise "no credit" and "cut prices" for cash, with the idea of showing the public the cost of time purchases. The possibility of selling more cheaply on a strictly cash basis will doubtless prove sufficient incentive for the expansion of this class of business; and by the operation of ordinary economic law will serve as a salutary check on instalment buying.

The cost of instalment selling, considered by itself, is high. It has been estimated to be as much as $800,000,000 yearly in the United States. This might be regarded as sheer economic waste were it not for the fact that tremendously increased production, made possible by the time payment privilege, has served to lower prices; so that the purchaser buys enough cheaper to pay the cost. Increased demand likewise keeps factories busy and gives employment to more workers. The protagonists of instalment selling insist that much of the prosperity of the United States since the War, in the face of strong European competition with its cheap labour, can be traced to the development of the home market by means of time-payment financing. It is even suggested that certain backward countries could benefit by the cautious introduction of this method of marketing.

It is typical of the diversity of opinion which still envelops the subject that some authorities regard instalment buying as tending to demoralise the purchaser, while others, probably more numerous, believe that it benefits the individual and society. "We are sorry," said the Babson Statistical Organisation in July 1925, "to see this stampeding to an instalment business. We don't believe that it is wise for anyone unnecessarily to get into debt, whether manufacturer, merchant or the public. Getting into debt has been the cause of most failures, and we are sorry to see another stratum of the public adopt it. On the other hand, is there any ethical reason why your employees are not justified in giving serial notes for their purchases of goods, as you are justified in giving notes for your purchases?"

The story is told by a writer opposed to instalment selling of a man on an income of $60 a week who had contracted for purchase amounting to $72 a week. He explained that he could not resist the persuasive suggestions of salesmen. But most observers agree that the American household had not lost its sense of proportion; and the occasional emergence of cases like this is a reflection on the credit departments of the sellers rather than on the principle of instalment selling. It is probably true, also, that further experience with deferred payments not only tends to make credit departments more cautious, but likewise trains the purchaser to be on his guard against undertaking obligations which he cannot meet.

This training must have considerable social value. The workingman who seeks to buy a piano or an automobile on credit soon learns the importance of having a good reputation for meeting his obligations promptly. The instalment merchant would prefer, as a matter of fact, to sell an expensive article to a man of moderate income with a proved reputation than to a more prosperous individual who was dilatory in meeting his obligations. Having bought his automobile or piano, having discovered the value of established credit, and having learned some of the mechanism of business, the buyer becomes a more stable unit in the community. He sees it will not be at all impossible for him to buy his own home, and, if his interests lie in that direction, to establish his own business.

The question is at once raised: why does not the instalment purchaser save the money in the first place? The psychologists could doubtless provide a complete answer; it is perhaps sufficient to say here that it is easier to pay for an article already acquired, especially if the sense of obligation is reinforced by a properly managed collection department, than it is voluntarily to lay aside each week or month a certain sum for the satisfaction of a desire that cannot immediately be realised. The wage-earner, attempting to save, necessarily finds it difficult to resist the demands made on his money, even though he manages to avoid petty temptations to squander; and instalment selling serves its best purpose when it provides the purchaser with products of enduring value. The fact is business could hardly go back to the pre-instalment days even if it wanted to.

An analysis of the population in the area between Boston and Chicago, the Great Lakes and the Ohio river, proved that for the purchase of an article costing $75 or more, after house-rent, groceries and clothing are taken care of, only 10% can pay cash; 30% are entitled to standard credit terms on a 30 to 90 day basis, and 60% must have four months to one year to pay. (See *Advertising and Selling Fortnightly*, April 22 1925.) It is only necessary to glance through the magazines and note the advertisements of hundreds of articles selling for more than $75 to realise that these businesses could not prosper if they were forced to reduce their output to the level of the cash de
Where, then, does the money come from to pay for these pro
It is difficult to escape the conclusion that people work hard
deny themselves casual expenditures in order to pay for
thing of real worth which they greatly desire. In many inst
too, it is certain that the article so acquired promotes greate
ductivity on the part of the purchaser.

The opposition to instalment selling has come from
sources. Partly, no doubt, it is inspired by manufacture
merchants who have failed to change with the times;
from other manufacturers and merchants whose goods w
lend themselves to this method of merchandising and
suspect, rightly or wrongly, that money is being diverted
the purchase of their goods. Open opposition has come
labour leaders, who probably feel that the working-man
paying for goods on the instalment plan will be less dispo
go on strike, and perhaps prove more docile in his att
toward his employer. A few banks have expressed them
as opposed to the instalment business, but the majority hav
willing to underwrite it in one form or another, otherwis
vast expansion already noted could not have occurred.

If instalment selling is to continue on a sound and prof
basis, there is no doubt that certain precautions must b
served. (1) It seems undesirable to extend this meth
sale to expensive products of great fragility or little int
worth. (2) An article combining high cost of operation, u
and depreciation, with little or no earning power, is for the
part unsuited for sale on long-term credit. (3) Special safeg
must be devised if the goods sold on time have little or no
when repossessed, or if the period of payment is likely to o
their usefulness. (4) No company should engage in
business without a well-equipped collection department
the direction of an experienced credit man. (5) Credit sho
granted only after sufficient investigation to give a reaso
assurance of the applicant's ability and willingness to pay.

The last point is by all odds the most important; there
hardly be any "problem" as to instalment selling if all
departments were properly managed. The seller is never f
to sell against his better judgment, and if abuses have cre
the seller must take the major share of the responsib
Fortunately, such abuses tend to rectify themselves. There

II. IN GREAT BRITAIN

The development of the system of purchase on the instal
plan in Great Britain and her colonies has proceeded on si
lines to those outlined above in the United States, thoug
in so accentuated a form. The idea was by no means n
England, since pianos were being sold on the hire-pur
system in London so far back as 1838. The present cen
however, has seen an enormous expansion in instalment se
which has been accelerated since the end of the World
One instance of this will suffice. In 1919 few motor-cars
sold on the instalment plan in Great Britain. Four years
one of those best able to judge computed that of the £15,00
retail turnover on motor vehicles, over £4,000,000 was do
the hire-purchase system, the greater proportion of this
amount being spent on commercial cars, including motor-
motor-lorries and motor chars-à-bancs. In 1925 the total
over had risen roughly to £52,000,000, of which not less
one-half was done on the instalment payment system.

The estimate of the hire-purchase traders is that be
50% and 60% of the furniture turnover and over 50%

piano, motor-cycle, sewing-machine and farm implement iess in the same year was done on the same basis. Even the sh Govt. in 1926 was selling by instalments surplus army s including aeroplanes and horses. The percentage of lment selling of factory machinery in Great Britain is, ver, very low on account of the fact that British limited ity concerns prefer either to take a discount for cash or to credit for the full amount of the purchase, since many of are public companies. Particularly remarkable, however, he successes reached through the sale of what may be called plements of business." For instance, the Remington Type- r Co. offered their portable typewriters on the instalment m in April 1925, the terms being an initial payment of .od., followed by eleven monthly payments of £1.1s.od. ng the sales for the six months preceding this offer at the rate o per month (a purely fictitious figure) it was found that the had increased in Oct. 1925 to 210, in Nov. to 269 and in Dec. 5. Thus in eight months instalment selling had increased ale of portable typewriters by over 200%, while the news- r advertising for the eight months was only about 5% e that for the preceding six months. To-day there is ically no great London or provincial department store is not selling furniture, gramophones, wireless sets, pianos sewing-machines on the instalment system.

ie financing of instalment selling in Great Britain has pro- d more slowly than in the United States. There is one rtant reason for this. The City does not like motor flotations y time; and it likes motor finance corporations even less. rdingly, these companies have usually had to go to the ance companies or their own directorate for their money. her, the British public has never become enamoured of motor s, and this dislike has extended to the shares of the finance panies. Yet there are several corporations in Great Britain a turnover of £2,000,000 to £5,000,000 per annum, and it is able that the present prejudice of both the City and the l investor against the shares of such concerns will be over- eventually. The system of financing motor hire-purchase eat Britain is identical with that in use in America. In the of a new car, however, it is usual to ask 25% in cash as a payment, the remaining payments being spread over a d of 6 to 18 months. It is common for the financing com- to charge 7% to 8% on each transaction for 12 months' mmodation. Obviously the actual rate of interest paid is o to 16% since the average amount on loan for each month ly half of the total. It must be remembered, too, that etailer is normally charging his customer from 5% to 8% he credit given, so that the net cost to the retailer is quite l. It will be clear, therefore, that the use of the instalment iod of selling entails a greater capital in relation to turnover cash selling. In other words, it tends to turn a former cash iess back to the basis of the old-fashioned credit business, 1 the customer took from 3 to 12 months' credit.

ie question which exercises British business men is whether xpansion of instalment selling similar to that which has n place in the United States during the past six years would lutary or dangerous. Goods sold on the instalment system in a sense, put into stock. One of the main causes of any iess slump is the excess of goods in stock. In a time of ession it is clear that the number of failures to meet payment d increase. How seriously would it increase? Further, as bank rate rose, the financing companies without large re- es would find their profits heavily cut, and possibly turned losses. At the same time it would be difficult for them to re new business on account of shortage of money and er rates of interest. British finance and British business are pelled to study this problem for themselves, since the con- ns of American business are so different and no serious p has occurred in the United States since instalment selling me so prevalent. The conclusion, however, would appear to hat the sale by instalment of articles with a re-sale value, of articles which do not depreciate with enormous rapidity, fe within almost any achievable limits. But very large sales in articles unsuitable for re-sale owing to the heavy depreciation, *e.g.*, clothes, might be extremely dangerous if acute business depression became rapidly felt.

The legal aspects of instalment selling in Great Britain are somewhat different from those prevailing in the United States. The property in an article purchased on "deferred payments" passes to the purchaser, *i.e.*, he becomes owner from the moment of the first payment, whereas under the hire-purchase system the purchaser merely acquires the right of possession, no right or property passing to him until the final payment has been made. It is vital therefore for the business which desires to sell its goods on the instalment plan to see that the actual contract signed by the buyer is one for hire-purchase, in which the successive payments are considered merely as rent, until the final payment is made, prior to which latter event the ownership remains in the vendor. Otherwise the purchaser after obtaining possession will be able to sell or encumber the goods, and an innocent purchaser or mortgagee will obtain priority of title.

Another contingency which has to be considered in Great Britain is that of distraint for rent. In the United States generally the landlord does not possess this remedy. All he can do is to put the tenant who is in arrears out on the street together with his goods. In Great Britain the landlord can enter upon the premises, seize the tenant's goods found therein, and sell them to realise the amount of rent due, and this liability extends to goods purchased by the tenant under the hire-purchase system, other than pianos, sewing-machines, safes, gas-engines and printing-machines. On a par with this is the danger of the purchaser becoming bankrupt, in which case the trustee in bankruptcy may, and probably will, sell the goods in question for the benefit of the debtor's creditors, unless the agreement has been drawn up in consonance with the best British practice. The legal situation, generally speaking, is so full of pitfalls and the law on many points so uncertain that any firm considering entering into the instalment business should take care to obtain the best legal advice on all phases of the subject.

It should be added that, from a credit standpoint, the instalment business has proved quite as safe so far in Great Britain as in the United States. The average losses through bad debts by the members of the Hire Traders Protection Assn. is under 2% per annum. One of the leading London firms reported recently that their loss from bad debts was less than 1% per annum. Even in one of the most risky fields, that of the sale of motor-cars by instalment, the average percentage of losses from this cause has never been placed above 2½% by competent authorities. (C. Ch.*)

INSULIN.—In 1889 Von Mering and Minkowski proved that the complete removal of the pancreas from animals produced signs and symptoms which are practically identical with those found in human beings suffering from diabetes mellitus. Previous to that year the pancreas, the gland which secretes powerful digestive enzymes into the first part of the small intestine, was not definitely associated with the utilisation of sugar by the animal body. It was soon shown that a small amount of pancreas grafted under the skin prevented the development of diabetes in an animal from which the rest of the pancreas had been removed. It was also discovered that blockage of the pancreatic duct did not produce diabetes, although degeneration of the pancreatic tissue, with the exception of numerous small structures called the islets of Langerhans, resulted.

Historical Notes.—These minute structures apparently unrelated to the acinous tissue which forms the digestive enzymes, were first noted by Paul Langerhans in 1869. Schafer was one of the first to suggest that pathological changes in the islet tissue might be responsible for the production of diabetes in man. He also suggested that "Insuline" would be an appropriate name for the hypothetical internal secretion by means of which some authorities believed the islet tissue to exert its control over sugar metabolism.

Experiments and Discovery.—In the year 1921 Banting and Best, at the University of Toronto, began a series of experiments the results of which proved that a substance could be obtained from the pancreas which would enable diabetic animals to utilise sugar. This substance was originally secured from the degenerated pancreas of the dog. The degeneration was produced by tying the pancreatic ducts, which causes an atrophy of the cells of the gland which produce the digestive ferments, but leaves intact the islet tissue. The available supply of degenerated pancreas was, of course, very small and efforts were soon made to secure the material from other sources. After a series of experiments in which small amounts of material were obtained from the normal pancreas of the dog and from the fetal calf pancreas, the active substance was obtained from the adult beef pancreas by alcoholic extraction of the fresh tissue. This discovery provided ample material with which to study in detail its action on experimental animals and to apply it to the treatment of patients suffering from diabetes mellitus. Animals from which the pancreas has been removed suffer from the same symptoms that the human diabetic experiences (*see* DIABETES). The sugar which cannot be used accumulates in the blood and is excreted in the urine. The normal animal stores sugar in its liver in the form of glycogen, but the diabetic liver does not form this substance. The administration of insulin to the diabetic animal corrects all these abnormal conditions and enables the animal to utilise carbohydrate in a normal manner. The average life of a completely depancreatised dog before the discovery of insulin was less than three weeks. These animals have now been kept alive, by the administration of insulin, for over two years and will undoubtedly live much longer.

Use and Value.—Insulin was first applied to the treatment of diabetic patients in Jan. 1922. The results have been uniformly successful, and thousands of patients are now being kept alive by the hypodermic injection of this material. Insulin does not cure the disease but replaces the internal secretion which the diabetic has lost the power to produce. The substance is administered subcutaneously and is not effective when given by mouth.

Standardisation.—Insulin is standardised by observing the extent of lowering of the normal rabbit's blood sugar produced by small amounts of the active material. The administration of too much insulin to diabetic patients is dangerous but the situation can be recognised by the occurrence of definite symptoms. The condition can be quickly corrected by the ingestion of sugar in any convenient form.

Employment in Cases of Coma.—Previous to the discovery of insulin a large proportion of diabetics died of coma. The intelligent use of insulin combined with proper dietetic treatment prevents the development of coma. Patients in coma can in most cases be rescued by the administration of large doses of insulin.

Specific in Diabetes Mellitus.—Insulin has proved to be a specific in the treatment of diabetic coma. It is invaluable in the treatment of severe diabetes mellitus. The use of the active substance in the investigation of the physiology and the biochemistry of the carbohydrates in the animal body has already brought to light numerous important new facts. It is quite possible that it is in this last field that insulin will contribute most to the welfare of the human race and the progress of medical science. (C. H. B.)

INSURANCE (*see* 14.656).—The years immediately preceding the World War were not extraordinarily interesting from the insurance point of view, although those of military age who then effected assurances had, later, excellent reasons for satisfaction that they had done so, since all who were insured with British offices were covered, whether or not the risks of war were specifically excluded from the terms of the policy.

I. GREAT BRITAIN

Life Insurance

Most of the British offices transacting what is known as ordinary life assurance had issued policies free from all restrictions, whereas some of the companies transacting industrial assurance had specially excluded the risks of war. All these companies which had done so decided, however, to waive their
rights. The value of the complete cover may be gauged
facts that, after the outbreak of hostilities, an additional pre
of £7·7·0% was quoted to cover the war risks, and that th
soon advanced to as much as 20% per annum.

Losses of the War Period.—What the World War mea
life assurance was indicated in a paper read by Mr. H. B
assistant actuary of the Commercial Union Assurance
before the Insurance Institute of London on Dec. 20 1920
ferring to the British offices, Mr. Brown estimated th
losses during the five years 1914 to 1918 inclusive as follows

1. Mortality in excess of the pre-War ratio resulted in a l
about £3,000,000 a year.
2. Depreciation in excess of the amount for just before th
was estimated at £4,000,000 a year.
3. The reduction in the net rate of interest due to the high i
tax resulted in a loss, as compared with the pre-War peri
about £500,000 a year.

The total losses, as compared with the period immed
preceding the War could, therefore, be estimated at, rou
about £7,500,000 a year during the five War years. In the
immediately before the War the total divisible profits o
British offices, in respect of ordinary life assurance, amo
to about £6,500,000 a year, of which about £6,000,00
divided among the policy-holders, and about £500,000
distributed among the shareholders of the proprietary
panies. During the War the normal profits continued
realised subject to the deduction of the special war losse
scribed. The special war losses thus exceeded the normal p
of the same period and it may be estimated that, down t
end of 1918, the War probably cost the life offices, as a
about five years' bonuses.

Post-War Conditions.—After the end of the War a great c
came over life assurance conditions. Instead of sufferin
preciation in security values year by year, the investm
began to appreciate, while favourable opportunities for
investment of funds continued. Against this fact had to
the consideration that taxation continued to be heavy.
offices were, however, relieved from the burden of the s
war mortality. They were still guided in their calculatio
premium rates by mortality tables relating to the expe
many years ago. Investigations are being made by th
stitute of Actuaries into mortality experience, but the r
are not to be expected for some time. Meanwhile, thes
bodies have issued the results of their inquiries into the e
ence of annuitants. These show that the longevity of annui
is distinctly greater than that of the general public. C
quently, in 1924–5 most of the British offices amended
annuity rates and would probably have further increase
prices asked but for the favourable rates of interest which
obtained on their investments.

While the difficulties of the British offices due to the
were serious, they were far less formidable than those of so
the continental companies in countries whose currencie
preciated heavily in value. Agreements were reached bet
the different countries respecting the basis of settlement
large number of policies were, for instance, effected by Bel
with German institutions, and an agreement was only re
at the end of 1925 respecting the settlements. In the U
States the effect of the War on the insurance offices was
paratively small. The American offices have mostly withd
from life assurance outside the United States. This secessio
provided opportunities for Canadian offices some of which
vastly increased their business within the last decade.
assurance per head in Canada and in the United States is
much greater than the corresponding amount in Great Bri
The average sum assured in the last-named is only about
of the corresponding sum assured in Canada and not
more than one-third the assurance per head in the United St

Industrial Life Assurance.—Criticism of the industrial
assurance system in Great Britain led to the appointmen
May 1919, of a departmental committee by the Board of T
to inquire into the business carried on by industrial assu

ıpanies and collecting societies. The report of this com- tee was issued in July 1920, and made various recommenda- s. Evidence was given before the committee that the con- ience and economy in collection could be improved by the oduction of the block system, under which an agent is gned an exclusive area for his work. The lead in the reduc- of working costs has been taken by the Prudential Assurance , which by gradual steps has lowered its working costs from ;% of the premium income in 1920 to 27·86% in 1924. This ıction made possible the introduction of a reversionary bonus em for the industrial policy-holders on the general lines ap- d to ordinary life assurance. The committee recommended appointment of an industrial assurance commissioner, and first report, which was issued in 1924, showed that the ap- ıtment had been of value to the assuring population, particu- y in its relations with the less satisfactory type of offices.

Fire Insurance

ire insurance was affected by the World War in so far as tions existed between insurance companies and the assured ountries which were at war with each other and also by the ıence of the War on prices on commodities. This was par- larly seen in the great increase in the amount of the claims ing 1919–20. In fact, the cost of the claim settlements has ı much higher in the post-War period than in the pre-War od. This development is illustrated by the estimates of the of the principal fires in Great Britain and Ireland. The cost hese, which only take into account fires in which the dam- amounted to £1,000 or more, as estimated by *The Times*, ounted to £3,300,000 in 1916, to rather over £4,000,000 in 7 and to £5,500,000 in 1918. In 1919 the cost of the prin- l outbreaks advanced sharply to £9,462,000; in 1920 they e £9,374,000; in 1921 they amounted to £8,128,000; in 1922 6,218,000; in 1923 to £7,192,000; in 1924 to £5,017,400; and 925 to £5,122,100. It will be seen that since 1920 the cost he claim settlements has very much declined, which reflects, ny rate partly, lower values.

osses from Fires.—In order that the total cost of all the fires in ıt Britain and Ireland may be estimated, it is usual to assume 50% may be added to the above figures in order to include the of all fires in which the damage amounted individually to less ı £100,000. Excluding the exceptionally costly years 1919–20 ill be seen, therefore, that the total cost of all the fires in Great ain and Ireland may be calculated at something like £10,000,- These figures are small in comparison with the cost of the fires orth America, in which the British insurance companies transact ge volume of business. The losses in the United States vary very h from year to year, since losses, when they occur, are usually emely costly. In 1922, for instance, the total cost was estimated bout £80,000,000.

osses from Earthquakes.—There have been no other losses com- ıble with those caused by the earthquake at San Francisco in). The British offices settled all claims made upon them prompt- n full. On Sept. 1 1924 there occurred the great earthquake in ın. The British and American insurance companies had, how- , been careful specifically to exclude the risk of earthquake from erms of the insurance. It was generally held that, with such finite exclusion, they could not pay claims for damage for which were in no way liable. In order, however, to show practical ıpathy with the Japanese people, the British companies offered eturn all premiums for the year which had been paid in respect roperty damaged or destroyed. The American offices also in- ıted their readiness further to return the premiums paid, and the tude of the insurance companies was known to have created a ourable impression in Japan. Claims were also made in respect he damage caused by a great fire at Smyrna in Sept. 1922, during ar between Turkey and Greece. Insurance companies main- ed that the fire was a direct outcome of war, the risks of which been definitely excluded from the policies covering property in city. Their attitude was upheld in the courts.

nsurance managers have pointed out that claims are frequently l in respect of damage for which they are not actually liable. By lvertence, some fact may have been omitted from the proposal n, and insurance companies, instead of standing on their rights, e been ready to settle claims. In the case of damage directly sed by earthquake and war, an essential principle was involved h, it was declared, they could not throw to the winds in justice he rest of the assured and to their shareholders.

he increase in the size of buildings has meant a great increase he values at risk in limited areas, and losses in respect of commodities stored in warehouses now amount to very large figures. As an example, a fire in a tobacco warehouse in the Port of London in April 1923 amounted to as much as £1,050,000. The risk of damage caused by civil disturbance, which has been apparent in various countries since 1911, has induced the insurance companies to make the fact clear that such damage is not covered by the terms of the ordinary fire insurance policy. The risk may usually be covered for a small extra premium, and many commercial enterprises now take the precaution of specially effecting such insurance. When there are no exceptional circumstances rendering the risk unusually hazardous it is accepted for a nominal rate. In cases, however, in which the risk has seemed to be a quite serious one, high rates have at times been paid. The London market is the principal centre for the acceptance of such risks, and business has from time to time been transacted there in respect of most countries.

Marine Insurance

In the years immediately preceding the World War there was a demand for the insurance of ships and cargoes against war perils. The insurance was granted as a rule at nominal rates; but the existence of the demand was indicative of the uneasiness which prevailed. Happily for the maintenance of British commerce, a government scheme had been prepared in advance, since it had been realised that, unless the resources of the nation were behind British shipping, vessels would, on the outbreak of hostilities, remain in port or would immediately take shelter there and overseas commerce would have been brought to a standstill. When war broke out, schemes were immediately brought into operation. That designed to cover vessels was worked through the instrumentality of the mutual shipping clubs, and provided that, in return for a premium, the Government should assume the greater part of the risk. For the purpose of accepting the war risk on cargoes a government office was established in the city of London under the auspices of the Board of Trade and with the active assistance of leading underwriters.

At the same time, underwriters at Lloyds and of the insurance companies themselves wrote risks, with the result that the lesser risks were accepted by underwriters at rates below those quoted by the government office, which was thus called upon to assume the more serious risks. Underwriters also granted war insurance in respect of many neutral ships and their cargoes to which the British Govt. scheme did not apply. The maintenance of the government schemes was, however, of great value, especially at times when losses due to the submarine warfare were very heavy. But for the fact that the government scheme was available for the acceptance of the war risk, in respect of cargoes in British ships, the rates of premium quoted in the open market must at times have risen to very high, if not prohibitive, levels. A substantial surplus was realised on account of the government cargo insurance scheme.

Missing Ships.—One difficulty which had to be taken into account was that a large number of ships became missing, and that it was not always easy to decide if these had been lost though direct war perils, or if their loss had been due to the risks of navigation, especially as some of the usual aids had been withdrawn. This question was carefully considered by a committee representative of shipping and underwriting, and it was agreed that, in the event of vessels becoming missing, there should be arbitration. The underlying idea was that an arbitrator, after hearing such evidence as was possible, could form an opinion as to the probable loss of the vessels, whereas if the question had been taken into court the proceedings might have been long and costly and no better decision could have been expected. In some cases the loss was apportioned by the arbitrator in such proportions, as seemed reasonable, among the war-risk and marine-risk underwriters.

Underwriting.—In spite of the War, or rather because of it, large underwriting profits were made in the London market during the period of hostilities and immediately after it. Underwriters took great risks in which they were, as events showed, justified. The remarkable rises in the values of ships and commodities meant that premium incomes were very much augmented, and many companies, new and old, were attracted to the business. Two years after the cessation of hostilities there was a marked reaction. With the sharp decline in the values of tonnage and commodities the amount of insurance business likewise declined. In view, especially, of the great increase in the size of the market, there was not enough insurance to feed it, particularly as underwriters had become accustomed to assuming far larger lines than they had been used to write before the War. Severe depression set in, and various attempts were made, extending into 1926, to try to obtain some stiffening of rates.

An extraordinary feature of marine underwriting in recent years has been the extended period over which claims have been presented. Before the War it was considered that an account could, for practical purposes, be considered as closed at the end of the third year. There might then be still a few claims unsettled, but the total of these would not be of sufficient magnitude to disturb the main results of the underwriting as then disclosed. After the War no such calculations could be made, and it is now common for claims to be presented for any of the years up to 10 after which the insurance was written. There were special reasons for such delays during, and immediately after, the war period, when tonnage was in keen demand. Any repairs that could be postponed were deferred for as long as possible, especially as the repairing yards were fully occupied with work.

MISCELLANEOUS

Workmen's Compensation.—Important recommendations respecting the system of compensation for injuries to workmen in the United Kingdom were made by a departmental committee appointed by the Home Secretary in May 1919, which reported in July 1920. The committee was presided over by Mr. Holman Gregory, K.C., M.P., and included representatives of the workers and of insurance companies. The committee, after a thorough examination of the subject, found that there were certain defects in the system then obtaining, but were of opinion that these defects could be remedied, largely without resort to a state system of insurance, although not without the introduction of a certain measure of state control. They proposed that, in future, definite percentages of the premium income should be expended in benefits to injured workmen or their dependents and that the remainder should be available for the management expenses or profits of the companies, and the payment of commission to agents, the latter not to exceed 5% of the premium income in any case. They calculated that there would thus be saved on the then cost to employers a sum of between £1,250,000 and £1,500,000 a year, which, under the existing organisation, would be paid away in expenses of management, commission and profits.

In order to provide against the risk to the workmen of uninsured employers proving unable to meet the obligations placed on them by the Act, it was proposed that every employer other than the Crown, a local or public authority, a statutory company or a householder in respect of servants not employed by him for the purpose of his trade or business, should be required to insure against the workmen's compensation risk. Employers with an annual wage-roll exceeding £20,000 were to be entitled to claim exemption from compulsory insurance upon compliances with prescribed conditions. Householders were excluded from the provision of compulsory insurance because, as the risk of accidents to domestic servants is small, the premium charged by insurance companies is more or less nominal, and also because it was considered that the cost and difficulty of enforcement would be out of all proportion to the numbers of persons involved. The committee was informed that a large proportion of householders already insured, and they believed that when the proposed increased liabilities were effective, few would be so unwise as to fail to cover their risk by insurance. Up to the end of 1925 no legislative action had been taken on these recommendations.

Motor-Car Insurance.—The general insurance department of a composite company includes miscellaneous forms of insurance, among the chief of which is motor-car insurance. During the World War comparatively little was done in this type of business. In 1919–20, when private cars again came into use, the insurance experience was very unsatisfactory. Costs of repairs were on a high scale, and there was an epidemic of thefts. For 1920 some of the leading companies reported substantial losses. Early in 1921 rates of premium were advanced, and since then the business has, on the whole, been transacted on a fairly profitable basis.

Credit Insurance.—Of recent years notable developments have taken place in the insurance of bad debts in British oversea trade. This business has for many years been successfully transacted by the Trade Indemnity Co., in which the great composite insurance companies have taken a financial interest. In 1925, on the initiative of Mr. A. M. Samuel, M.P., then head of the Overseas Trade Dept. a committee of bankers, financiers and business men was set up in order to investigate the advantages that might be secured from a further extension of insurance facilities for this purpose. This committee, whose report was issued in the spring of 1926, made certain recommendations with a view to a further development of this type of business. (C. MA.)

II. THE UNITED STATES

The business of insurance, with its basic element of m
assistance, has shown a progress in the past 15 years bot
volume and ramification unsurpassed by that of any
industry. In the United States as in no other country ha
surance in all its various phases become universally recognis
an essential of commerce and industry. To this fact ma
attributed in large measure the achievements of Americ
business enterprises. Insurance coverages permit men
corporations to hazard their resources on new developm
without fear of loss from natural and unavoidable catastro
The importance of insurance as a national factor may
visualised by the fact that at the end of 1925 the comb
companies had a premium income of $4,000,000,000 with
admitted assets of over $14,000,000,000.

Life Insurance.—The life insurance companies aim to su
the demand for life insurance as best suits the wants of all cla
and conditions of men. The old life insurance policy, while
business was in an experimental stage, was so loaded
conditions and restrictions and so limited in its applicati
that comparatively few persons availed themselves of this
tection; but recently numerous forms of policies have
devised to suit the wants of all sorts of people, and the condit
and restrictions have been eliminated to such an extent
practically the only exaction remaining is that the person ins
shall pay his premium. The last 15 years have been not
prolific in the invention and development of plans of life in
ance. Ordinary life insurance, through its several classe
policies—whole life, limited payment, term and endowmen
provides ample choice for the selection of a form of protec
best suited to the needs, financial resources and saving abili
of all classes from the average wage-earner to the multi-mill
aire. The great industrial insurance companies, with t
weekly payment contract, reach the homes of the work
classes and enable them to provide for funeral benefits
against personal distress and dire want. Paramount among
recent innovations in life insurance is group insurance, thro
which industrial corporations collectively insure employees
gardless of age or physical defect. The premium is lower than
which could be obtained through individual contracts, by rea
of the overhead savings in insuring a large number under
policy. Other introductions include business and partner
insurance, disability, double indemnity benefits and mon
income insurance.

The comparative aggregates of the old line legal res
companies are proof of life-insurance expansion. In 1910
total life insurance in force was over $16,000,000,000 and
aggregate admitted assets totalled something short of $4,c
000,000. During 1910 the combined companies had a t
premium income of about $600,000,000 and wrote during t
year a trifle over $2,500,000,000 of new insurance. The t
for these companies for the year ending Dec. 31 1925, show t
legal reserve life insurance companies had over $71,000,000
of insurance in force, including industrial business, and asset
over $11,600,000,000. The premium income was almost $2,5
000,000 and the new insurance written in 1925 was over $16,0
000,000. In a country with a population of 115,000,000 peo
there were in 1926 practically 100,000,000 policies of life ins
ance in force, on what were estimated to be about 60,000
lives. So extensively has the idea of life insurance been s
in the United States that it is estimated that more than e
other person in the country is insured.

Fire Insurance.—Because fire insurance has for years b
recognised as an essential adjunct of industrial and comme
enterprise, its growth in the years since 1910 has not been, f
a comparative standpoint, as spectacular as life, casualty
miscellaneous insurance. Nevertheless, its progress has k
pace with the industrial development of the country and
met the demands imposed upon it by the upheaval occasioned
the World War and the evolution of recent years and rec
inventions. While in the period there was nothing in the nat
of a catastrophe such as the conflagration and earthquake

Francisco in 1906, nevertheless losses were uniformly high consistent underwriting losses were incurred. In the period, there were upward of 75 single fires in the United States ing property losses of over $2,000,000, and reaching as high ne instance as $35,000,000. The energy and resources of the insurance executives during the period have been directed g the lines of fire prevention and fire protection work. -insurance engineering experts are now consulted in every ding operation, and there is no incorporated village or city ch has not taken cognisance of the fire hazard by the organ- on of fire departments, by water systems and by the adoption re prevention and protection ordinances. Control of the sical hazard, however, has been offset by the development of moral hazard to which a great part of the fire losses at the ent time may be attributed. The growth in resources and me of the fire insurance business is indicated by a résumé e total transactions of the companies. The figures show that assets of the companies totalled $550,000,000 in 1910, were tly over $700,000,000 in 1915, over $1,000,000,000 in 1919, over $1,730,000,000 at the end of 1925. In 1910 the premium me of these companies was but $287,000,000. It had hed $353,000,000 by the end of 1915 and almost doubled f in the intervening four years, for during 1919 it was almost ,000,000. Consistent progress during the succeeding years lted in these companies showing a premium income in 1925 901,000,000. Modern industrial advancement has done h to stimulate the growth of fire-insurance companies, while he same time demanding a wider scope of indemnification. has resulted in the undertaking of many additional lines surance by the fire-insurance companies, the principal of h is motor-vehicle insurance. Other lines of insurance sacted by fire companies include tornado, windstorm and one, hail, inland marine, sprinkler leakage, riot and civil motion, air-craft, explosion, earthquake, rain, crop, flood, and freeze, tourist baggage, parcel post, water damage, use occupancy, and registered mail. While the total premium me from many of these lines is at the present time small, rtheless it indicates a comprehensiveness of service quite in ing with the modern tendency to place upon insurance the len of preventing economic or financial catastrophes from possible anticipated contingency.

ean Marine Insurance.—Ocean marine, which is the oldest wn form of insurance, reached a volume during the period of World War never before approached. The demands placed n insurance companies for marine coverages exhausted the urces of existing carriers, and induced the entry of most of arger fire-insurance companies into this field. To supplement her the demand during the War, there was organised a bureau ar risk insurance by the U.S. Treasury Department. This of inestimable assistance to American commerce, and pro- ed a premium volume during the period of its existence of ut $50,000,000, the bulk of which was obtained between . 17 1916 and April 27 1918—almost $39,000,000. Ocean ine insurance, however, has not progressed in America with r forms of insurance, because it is bound by national laws subject to national taxation, though it is an international ness and in direct competition with international carriers, stricted by laws and not subject to the high taxation im- d upon American carriers. The premium volume of Ameri- companies for ocean marine insurance amounts to around 000,000 per year.

asualty and Miscellaneous Insurance.—Casualty insurance is latest development among the general classifications of rance prevailing in the United States. To a great extent it fies modern progress, and the bulk of its business is directly to modern economic and inventive conditions, workmen's pensation and automobile liability insurance being the two ing classes in regard to premium volume. The forms of alty and miscellaneous insurance cover accident; automobile sion, property damage, and liability; bail bonds; bank sits; burglary and theft; credit; check forgery; engine machinery; fidelity; flywheel; health; live stock; liability, public, elevator, employers, etc.; plate glass; property damage and collision; surety; steam boiler; sprinkler; title; workmen's collective and workmen's compensation. In 1910 casualty and miscellaneous insurance companies had total assets amounting to about $300,000,000, while their total premium receipts were $94,000,000. The leading classes of business were liability insurance, with premiums of $28,000,000; accident, with premiums of $23,000,000; fidelity and surety, $15,000,000; health, $6,000,000; plate glass, $3,500,000; burglary and theft, $2,500,000. In 1925 we find that companies offering the various forms of casualty insurance and miscellaneous insurance had over $1,700,000,000 of assets, while their premium volume was almost $650,000,000. In that year the leading classes of coverage were as follows: workmen's compensation, premium income, $130,000,000; automobile liability, $117,000,000; surety bonds, $56,000,000; liability (public, etc.), $47,000,000; accident, $45,000,000; automobile damage, $41,000,000; fidelity, $33,000,000; burglary and theft, $28,000,000; health, $20,000,000; plate glass, $16,000,000. It is worth noting that the writings in two of the individual lines of casualty insurance in 1925 exceeded the total writings in all classes in 1910. (A. L. J. S.)

INSURANCE, SOCIAL (*see* 14.656).—Social insurance is the name given to the arrangements, whether provided by the state or private agencies, whether voluntary or compulsory, for paying a certain sum of money, or goods and services in kind, as compensation for the loss resulting from certain kinds of emergencies which in their nature lead to diminished capacity to earn or to an increase of expenditure. The object of all branches of social insurance is to protect the workman against the fact and fear of insecurity and its accompaniments—the exhaustion of savings, a lowered standard of living and recourse to public or private charity. This device gives him a legal right to a definite sum. The causes which may reduce the workman to want are of two kinds: those which are unexpected, catastrophic and undesired emergencies, and which entail a lowered capacity to earn or an inability to earn; and those which are desired and normal happenings, but entail an increase in expenditure even where the income has not diminished. In the former class should be included industrial accidents and occupational diseases, non-industrial accidents, ill health, invalidity, blindness and unemployment, burial, unprovided widowhood and unprovided orphanhood and, in the latter, old age, maternity and provision for growing children. In order to deal with these problems modern states have created new institutions, assumed control of existing machinery and provided subsidies, and their legislation on the subject constitutes in its totality a veritable code guaranteeing the workman a minimum of security in all his emergencies.

I. GENERAL INTRODUCTION

Origin of Social Insurance.—Social insurance began as a device employed voluntarily by workmen to protect themselves against emergencies. Trade unions, friendly societies, employers' welfare funds and private insurance companies organised provision for the cost of burial, ill-health and unemployment, and settled the rates of contributions and of benefits. Germany, under Bismarck, was the first country to realise the value and necessity of the compulsory method of insurance against sickness, industrial accidents and old age, which was applied to practically the whole industrial population by the laws of 1883, 1884 and 1889. Great Britain was the first to experiment (in 1911) with a national compulsory system of unemployment insurance, and possesses the most comprehensive system of pensions for widows and orphans of any country in the world. The schemes first introduced in the Central and Western countries in Europe are now being copied by other countries, by the South American Republics and Japan.

Since the War new risks have been provided for in countries where before only one or two were recognised. Classes hitherto excluded from insurance legislation are being brought increasingly within its scope. Gradually the families of insured members are being recognised as standing in equal need of insurance with the breadwinner. Money and service benefits are being added to bring them up to an amount which will give the insured population a minimum sufficient to maintain them in efficiency.

A new factor which is likely to grow increasingly insistent is the effect of compulsory insurance on the costs of production and consequently on international competition. It is in the interest of countries like Great Britain and Germany, which spend heavy sums annually on social insurance, to press for the extension of similar activities in other countries. In 1924 Great Britain spent an aggregate of some £170,000,000 (contributed by employers, workers and the State) and Germany some £60,000,000 on the various branches of the social insurance systems. The International Labour organisation has adopted at its annual conferences a number of conventions and recommendations on unemployment insurance, maternity insurance and workmen's compensation, and the exhaustive studies made by its staff provide an armoury of information.

In Great Britain legislation in connection with provision against social risks, either by way of compulsory insurance, provision by the employer or regulation of voluntary insurance falls under the following heads: compensation for industrial accidents and industrial disease, old age pensions, sickness and invalidity insurance, maternity, unemployment, widows' and orphans' pensions, blind persons, family endowment (provision for children under the War Pensions and Unemployment Insurance Acts). Each of these is dealt with below.

Great Britain may claim to have the most comprehensive system of social insurance in the world, but most industrial countries have adopted some schemes covering one or more risks. The two branches most highly developed in the United States of America are workmen's compensation and pensions for widows and orphans.

Basis of State Action.—Why does the State interfere in the matter of social insurance? From the days of the Elizabethan Poor Law the State has been the ultimate resort of those who are destitute. When all other means had failed those in distress, they could turn to their parish for relief, though this relief has generally been inadequate and granted only under deterrent conditions. Social insurance reduces the number of those who will become destitute.

Moreover, unless compulsion is applied, few will make adequate provision against these social emergencies. But to the community as a whole, assuming no change in our habits, these risks are unavoidable, and it is now regarded as the business of the State to contrive that they shall be provided for. Even the individual who is fully conscious of the dangers he runs will frequently be unable to make adequate provision, and therefore Parliament may decide that the immediate costs should be borne by the employer or by the State itself. Another consideration has been slowly emerging. Only Parliament can decide that large bodies of people shall be compulsorily insured. When it has gone so far it cannot allow private organisations to administer the insurance badly or at too great a
Since the administration is extremely simple, once the act
has worked out costs in relation to benefits, there is everywh
tendency for social insurance to be organised through St
monopolised funds. Behind all these arguments of a prac
nature lies the consideration that every worker is an asse
the State, and the community as well as the individual su
when his health or efficiency is impaired.

Limits of Social Insurance.—Many of the older advocate
social insurance are beginning to be nervous about its col
growth, and complaints are frequently made of the heavy bu
which it imposes on the nation. It is misleading, howeve
lump together, as some critics do, aggregate expenditure
pensions, health and unemployment insurance, workmen's c
pensation and burial insurance premiums, and bring o
grand total of some two or three hundred million pounds w
is called "national expenditure." It is not national expendi
in the sense that it is all provided by the Exchequer. On w
men's compensation and burial insurance the State pays noth
And its contributions in respect of the three compulsory in
ance schemes are, of course, only a fraction, even if a subs
tial fraction, of the total cost.

The following tables show the respective shares of the work
the employer and the State in Great Britain.

Health, Widows and Orphans and Old Age Contributory Pensio
(weekly contributions)

	Worker	Employer
Men	9d.	9d.
Women	6d.	7d.

State contribution (*a*) Health: two-ninths of the total cost of ben
(payable on disbursement). (*b*) Pensions: £4,000,000 a year. (T
will be a slowly rising *additional* cost to the Exchequer in respe
old age pensions at 70, equal to £1,700,000 in 1926–7 and £4,700
in 1935–6. At the same time there will be a relief to the Exchequ
respect of health and unemployment insurance. The *net* Exche
charge on all these pensions will, it is estimated, be £5,700,00
1926–7, rising to £6,400,000 in 1935–6. The finance of the sch
is complicated; it will be found discussed in detail in the Gov
ment Actuary's Report on the Financial Provisions of the Wido
etc., Pensions Bill, Cmd. 1925.

Unemployment
(weekly contributions)

	Worker	Employer	State
Men	7d.	8d.	8d.
Women	6d.	7d.	6d.
Boys (16–18)	3½d.	4d.	4⅝d.
Girls (16–18)	3d.	3½d.	4⅜d.

Moreover, it is plain that if the State were not paying t
millions which have been reduced by the Economy Act of
into the insurance funds, it would be forced to pay as much
perhaps even more, in other ways—*e.g.*, in supporting a pu
health service, in various palliations of unemployment, in e
Poor Law relief, or some similar form of public assista
State-aided insurance, in short, is judged to be true economy.
it is that we find extensions and improvements being advoca
in all directions. The paradox of social insurance, indeed, is
steady growth in spite of constant attacks upon it and the l
of any visible widespread enthusiasm for it.

Unification.—Parallel with the movement for the extens
of social insurance there is a movement for its unification.
present all the emergencies are treated by different adminis
tive machinery, with different methods for raising funds
different rates of contributions. Since the objects underly
all these schemes are broadly the same, the prevention of
titution, the abolition of the fear of insecurity and the provi
of a minimum in all periods of need, it is undesirable that th
variations should continue. Moreover, the workman, the
sured person, wishes to be spared the trouble of dealing wit
host of organisations. However the present medley has be
brought about, it is surely desirable that all these diffe
schemes should be unified. And unification must be taken

not merely the correlating, co-ordinating or riveting er of all the schemes, but their complete amalgamation ject of finance, administration and underlying principles. advantages claimed for a unified scheme are:—

The problem of social emergencies will stand out prominently eps for prevention will thus be encouraged.

Administrative expenses would be very much less and insur- ould be provided cheaply. The benefits given for the same ms will consequently be higher.

The workman dealing with one body will be more likely to his rights and how to claim them.

Existing anomalies, such as death by industrial accident re- different treatment from death through a non-industrial nt, or natural causes, will be abolished.

A department of state will be better able to tackle the whole m than the variety of agencies that now are at work. Im- nents will be carried out more easily, investigations will not npered by private interests.

doubt such a department of state would be a huge affair. ould the change over from the present system be easy. l interests and inter-departmental jealousies would have overcome, and the machinery for dealing with every d workman greatly extended and improved. But that is rection in which social insurance is tending, and not only at Britain. In some of the more important recent codes of insurance, those of Russia and Czechoslovakia, sickness, ge, invalidity and death are treated in unified schemes. roposed French and Australian schemes are also very ehensive. The unification of social insurance is also being ed in Germany.

II. WORKMEN'S COMPENSATION

Great Britain the Employers' Liability Acts of 1880 and orkmen's Compensation Acts of 1897, 1906 and 1923 con- the legislative basis for providing compensation to eople who suffer "personal injury by accident arising out l in the course of employment," or in consequence of one industrial diseases brought specifically under the Act of In the Act of 1880 negligence had to be proved against nployer. But in the Act of 1897 employers were held to be isible for injuries arising out of work in their establish- , even when negligence could not be proved, on the ground he workman was unable to bear unaided the monetary loss injuries involved. In 1906 the scope of workmen's nsation was greatly increased. In the Workman's Com- tion Acts the individual employer is alone held to be isible for paying compensation, and neither the worker nor ate makes any contribution towards the cost. It is still o the employer to choose whether he will insure himself in private insurance company against the risk of having to compensation claims, or pay them himself.

number of workpeople who obtain some measure of tion is estimated at over 17,000,000, but the statistics of orking relate only to some 8,000,000, to those employed ipping, factories (to which the Factory and Workshop apply), docks (including wharves, quays, etc.), mines, ies, constructional work (not including building construc- and railways.

es of Compensation.—The rates of compensation laid down e Act of 1923 are broadly: for partial incapacity, a sum to half the difference between the man's earnings before fter the accident; for total incapacity, half-wages up to a num of 30s. a week. Compensation is payable from the day of incapacity. Where, however, the incapacity lasts ur weeks, the first three days also rank for compensation. in addition to the loss of at least half his wages the workman st cases suffers the loss of the waiting period, the cost of s, medicines, artificial limbs, etc., the cost of training for job; and in all cases where disputes arise he is liable to the costs of litigation. Although in theory the employer le to bear the total costs of an accident, in practice it is ful whether much more than a third of its financial burden ed upon him, the workman bearing still about two-thirds loss.

In fatal cases a sum of between £200 and £300 is paid to the widow, which may be raised by additional allowances for children up to a maximum of £600. It should be observed that whilst some provision is made for dependents in the case of fatal industrial accidents, no provision is made for their needs in the case of non-fatal accidents.

The Home Office has estimated that the total of the charges and expenses for workmen's compensation in the seven great industries was not less than £5,000,000 in 1913 and 1914, £6,000,000 in 1919, £8,500,000 in 1920, 1921 and 1922, £9,000,000 in 1923. But these figures relate only, as we have seen, to about half the industrial population. Assuming that the accident rate in the other occupations is only half what it is in the seven great industries, then in 1923 the cost of workmen's compensation to employers must have been about £13,500,000. Since, however, the workman is still made to bear between one-half and two-thirds of the loss resulting from an accident, it has been estimated that the annual loss due to industrial accidents and diseases amounts to between £30,000,000 and £40,000,000 per annum.

The administrative expense in the case of workmen's compensation has for many years been about 50% of the premium income. The Holman Gregory Departmental Committee reported in 1919 that "During the last five or six years the employers have had to pay £100 in premiums for every £48 paid out in benefits to insured workmen." The companies agreed in 1923 to confine administrative expenses to within 40% of the premiums they received, with a further reduction to 37½% at the beginning of 1927.

Although employers generally insure themselves against the risk of being called upon to pay workmen's compensation, they are not bound to do so, and very frequently the smaller employers fail to make any such provision. Cases thus arise where the workman is obliged to take less than he is entitled to by law. It has therefore been proposed that employers should be compelled to insure, so that the workers may be certain of receiving compensation.

Over 30 diseases have now been scheduled as being due specifically to various industries and in respect of which compensation is provided. But in the many kinds of industrial diseases which may also arise apart from the employment—*e.g.*, bronchitis in cotton workers—no compensation under the Act is provided. This system is also criticised as involving frequent litigation and delay in payment. Moreover, agents are alleged frequently to induce injured workmen to take smaller amounts than their due. Insurance companies, as often as they can, induce the workman to accept a lump sum, since in spite of their heavy cost of administration they have only clumsy machinery for making weekly payments and for the review of benefits as the children grow older or die. Lump sum payments very frequently mean the rapid dissipation of benefits.

Neglect of Preventive Measures.—Perhaps the most serious fault is the neglect of preventive measures. There is little evidence of a steady and significant decline in the number of industrial accidents, of which about 400,000 occur annually. The neglect of the well-known and tried devices of the "Safety First" Association, with their educational influence on the workpeople, both by employers and by the insurance companies, is a glaring piece of carelessness. Second only to this in importance is the scant attention paid to the rehabilitation of injured workmen.

It has been suggested that a Government fund for insuring employers against the liability to pay compensation could be run at a much lower administrative cost than private insurance. In the United States competitive funds have an administrative expense of 6 to 9%. Another suggestion is the linking up of workmen's compensation with health insurance and the scheme for widows' and orphans' pensions. This might be desirable in itself, but would necessitate compulsory insurance in a state scheme. It would indeed involve altering the whole basis of the present law. The device of workmen's compensation has been so widely adopted that the International Labour Organisation was able to adopt a convention on this subject at its conference in 1925.

III. PENSIONS

Old Age Pensions.—Old age pensions were first granted in Great Britain by the Act of 1908. This Act, which was amended in some particulars by the Acts of 1911, 1919 and 1924, provided for the payment of pensions to all persons who had reached

70 years of age, who had been British subjects for at least 10 years or if natural British subjects had resided in the United Kingdom for a period of not less than 12 years since attaining the age of 50.

The amount of the pension was to be adjusted to the means of applicants. They must be below a certain standard before they could claim, and the pension was in no case to exceed 10s. a week. The scheme was non-contributory in character, and the entire cost of the pensions and of the administration was defrayed out of national taxation. Under the existing Acts, the application for a pension must be made, in the first place, at the local post office on a "claim to pension" form. The local excise officers appointed under the Acts by the Treasury to be pension officers report on the means of the applicant; the pension committee decide on the validity of the report and the rate of pension. The claimant or pension officer, if dissatisfied with the decision, may appeal to the Minister of Health within seven days of receipt of the notice of the committee's decision. If the claim is allowed the applicant obtains his weekly pension at the local post office.

The Old Age Pension Act of 1908 was the first Act to provide permanent public assistance outside the Poor Law. Its advocates argued that even if the workman could save enough to provide for ill health or unemployment he could not be expected to save enough to provide both for himself and his wife after 70. The scheme adopted bore signs of its origin in the older system. The pension is granted only to those who are not, it is true, destitute, but necessitous. No one is eligible who has an income of £50 a year or over. The amount of the pension varies directly with the need of the applicant. The poverty qualification infringes the idea of social insurance, the essence of which is to grant a legal right to a definite sum. The pensions scheme, it is true, does this, but grudgingly and on conditions which savour of the Poor Law. It involves vexatious inquiries; it discourages thrift and the aid of relatives; it is unjust. On the other hand, it is the first branch of social insurance in which the State intervened directly. Its inquisitorial character was inevitable in a non-contributory scheme.

In 1910, the first full year of the working of the old age pension scheme, the cost was £8,468,128. In 1924 it amounted to £24,000,000. In 1965 the Government actuary estimates that the same scheme will cost more than double that amount, some £57,000,000. This is attributed to two causes, the growth in the annual number of births between 1850 and 1890 and the decline in the death rate. The cost of granting universal old age pensions without tests or a means limit would be an additional £14,000,000 a year, rising to about £19,000,000 in twenty years. The total net cost of administration of the scheme, covering the expenses of the pensions committee, was estimated for the year 1924 at £800,000. This constitutes an administrative expense of $3\frac{1}{3}\%$.

The operation of the old age pensions scheme revealed an appalling mass of poverty among those over 70, and it was known that the lot of those between 65 and 70 was little better. The Act of 1925 introduced contributory old age pensions at 65, and also abolished the means disqualification for those insured. This Act, however, allows the non-contributory pension at 70 to continue until it is slowly absorbed by the contributory insurance scheme.

Non-contributory old age pension schemes exist in:—

(1) Australia, Denmark, France, Great Britain, the Irish Free State, New Zealand, Norway, in certain of the United States and Uruguay.

(2) Contributory pension schemes have been introduced in Rumania, Spain, Switzerland, Belgium, Italy, the Netherlands, the Serb-Croat-Slovene kingdom, Bulgaria, Czechoslovakia, and recently in Great Britain.

The Act of 1891 passed by Denmark for assisting the aged has thus been the forerunner of the modern schemes of old age pensions and insurance which have now been adopted in most industrial countries.

Old age is assumed to occur at some stated age which varies from 50 to 70 years according to the country.

Pensions for the Blind.—In Great Britain the Blind Act of 1920 provided that all blind persons of the age of 50 or over should be granted pensions at the same rates and on the same conditions as those applying to persons of 70 and over. The local authorities are empowered to make provisions for the blind—such as the establishment of workshops, assistance to homeworkers,
teaching and assistance in book production—out of the
funds. Such provision is aided by a state grant.

Widows' and Orphans' Pensions.—The contributory O
and Widows and Orphans Act 1925 marked a new developm
social insurance in Great Britain. Two methods are ope
Government for making provision for widows and orphan
of compulsory contributory insurance, or as it is tern
Great Britain, contributory pensions, or that of non-c
utory pensions.

From January 1926 widows have received a pension of
week, together with 5s. for the first child under 14, or under 1
child is still attending school, and 3s. for each of the others
scheme has been linked with one for providing old age pens
10s. a week at 65 instead of 70 to all insured men and wome
out inquiry into their means. Both these schemes are joined
existing scheme of contributory health insurance and th
contributory old age pensions. It has been estimated th
benefits accruing to an insured man and his dependents un
Act are roughly equal in value to an endowment assuran
£200 payable at death or at the age of sixty-five.

But instead of being entitled to an old age pension, if his
was very restricted, at the age of 70, he will under the new sch
able to draw his weekly pension of 10s. for the rest of his
reaching the age of 65, whatever other sources he may poss
whether he gives up work or not. His wife will also be entitl
pension at sixty-five.

The new scheme provides also that on his death—at whate
—his widow will receive a weekly pension of 10s. until her
unless she marries again; if he leaves children at school under
of 16, his widow will be entitled to draw 5s. a week for the eld
3s. a week for each of the others; and if the children are mot
as well as fatherless payments will be made in respect of the
they reach the age of 14, at the rates of 7s. 6d. a week for the
child of a family and 6s. a week for each of the other children.

The pension age, it should be observed, is reduced only in t
of those who are insured, and it is only in their case that the e
means disqualification is to be removed. Those who have n
insured as workers remain under the existing system. The c
health insurance may be expected to be lessened by the s
because many workers who will be drawing their old age pens
65 will no longer be entitled to their invalidity benefits. Un
Economy Act 1926 the Government lessened, therefore, th
contribution to health insurance.

The first full year in which old age pensions at 65 will be p
be 1928–9, when the costs will be £12,400,000, from which th
steadily rise up to the maximum in 1965–6, when they will a
to £21,500,000. In that year the total cost of old age pensio
be £85,900,000. In the first complete year (1926–7) the
widows' and orphans' pensions will be nearly £11,000,000, a
amount will rise steadily until 1965–6, when it will be £38,8
In that year the total payment on account of old age pensio
widows' and orphans' pensions will be £125,000,000.

For many years to come the old age pensions scheme is t
growing liability and the war pensions scheme a dwindling o
1926 these two services cost about £94,000,000. In forty yea
will cost about £90,000,000. After that the state grants out o
grow less until, as the percentage of those who come in after
increases, the Government will be called on to pay less and les
its liability will gradually dwindle to nothing.

The contributions to be paid by the insured persons are 4
week by a man and 2d. by a woman, while the man's employe
pays $4\frac{1}{2}$d. and the woman's $2\frac{1}{2}$d. The State also contributes it
under the new scheme.

IV. INDUSTRIAL INSURANCE

Abuses of the Unreformed System.—By industrial life a
ance or burial insurance the working classes obtain be
sufficient to cover the cost of burial. This form of insura
common in Great Britain because of a very deep and

l terror of a pauper's funeral. Between 1903 and 1924 the ıt spent by the workers on this branch of insurance sed by about 400 per cent. The great success of the in-al insurance companies is due to the army of some 70,000 s employed by them to collect weekly the small premiums. l insurance is brought by them to the worker's home in ι form and at such a price that he can provide for it out of ıall earnings. Indeed, the agents have been able to per- many working class families, and especially the mothers, .e out one or more policies for each member of the house- so that it is a common thing for a workman to spend en 1s. and 2s. a week for this branch of insurance. It has :laimed that "there is scarcely a home among the millions working classes in this country which is not visited at once a week by these agents." In 1921 it was stated here were over 50,000,000 "industrial policies" in force, ıich £35,000,000 was paid annually in premiums. To this l be added the interest on invested capital. It is estimated :xpenditure for "death" benefits is equal to about twice ee times the amount spent on health, maternity, and dis-ent taken together.

s business has been subjected to very strong criticism. A tmental committee, presided over by Lord Parmoor, .ed in 1920. It was found that some 44% of the premiums in agency and management charges, proving that this ɔd was needlessly costly. Excessive house-to-house can-.g led to considerable overlapping and wasteful competition. ersistence of the agents led to the purchase of policies by ıs who could not afford to pay for them, with the result ome 5,000,000 policies lapsed annually. There had been :s and scandals and the system was full of abuses.

ee policies were proposed for dealing with the situation:—

To nationalise the business and to provide burial benefits *lsorily* under the national insurance scheme.

To control it, to remove the more flagrant abuses, and to he joint charges of administration and profits.

To control it, but to leave the insurance companies to remove ıin causes of complaint themselves.

'armoor committee recommended this third policy, which ı effect adopted by Parliament.

utory Regulation.—The Industrial Assurance Act 1923, tcome of the report, made the Chief Registrar of Friendly ies the industrial assurance commissioner, with wide s, and every office, whatever its constitution, which .cts industrial assurance business is now required to make ıs to him. The companies are required to make an addi- deposit of £20,000 in respect of industrial assurance :ss, and the collecting societies have to make a similar it.

accounts of the industrial assurance business must be kept .te from other branches of insurance business. The commis- has power to examine into and report upon the affairs of any ıny or collecting society where an offence has been committed ıis opinion is likely to be committed. Every office transacting usiness had to have a valuation made by an actuary not later he end of 1925, and where a deficiency was disclosed the com-ner might present a petition for winding up the company. ıpts are being made to lower the administrative expenses in vays. The "block system" of canvassing for business, by a definite area or number of blocks of houses is assigned to one is being substituted for the anarchic method which allowed agent to canvass where he would. Companies will still com-vith one another, but not the agents of the same company. is also an increasing tendency to pay agents by salary rather ɔy commission. This will give the company greater control, ncourage sounder methods of obtaining clients. In the third efforts are made to induce regularly employed people to pay ums monthly. Fourthly, higher premiums are canvassed for er to lower the proportion of administrative expense. One ıny working along these lines has reduced the expense from o something below 30% in a few years. But we are warned rom even this company we must expect no reduction of the f administrative expenditure to premiums below 20%.

re are strong arguments against allowing the business to ı voluntary. The present method, apart from incidental , is open to objection on the ground of its wasteful administra-nd the undesirability of continuing the voluntary method the compulsory is adopted in related branches of insurance. Now that we have a system of life insurance endowment policies in the widows' pension scheme, it is contended that it is absurd to omit life insurance burial policies.

Many countries grant this additional benefit in conjunction with their health insurance schemes, an arrangement which keeps administrative expenses low. The State can administer this benefit at an expense below 2% of the premium income.

V. HEALTH INSURANCE

The National Insurance Act of 1911 constituted in many respects a new departure in British social policy. Workmen's compensation was already in operation, but the judicial justification of the new scheme was entirely different, whilst the state was, and still is, very little concerned in its actual administration. The Old Age Pension Act might be regarded as the offspring of the old ideas of Poor Law, and it was very easy to administer. The device now introduced of contributory insurance conveying a legal right to a definite amount was unknown previously in Great Britain. The Act of 1911 was in fact a novel experiment, both as regards the health insurance and the unemployment insurance sections.

Health Insurance.—The National Insurance Act 1911, Part I., makes provision for insurance against loss of health and for the prevention and cure of sickness. It is compulsory on all manual workers between the ages of 16 and 70 and non-manual workers with incomes under £250 who have not claimed the right of exemption. Over 15,000,000 persons are included. The normal benefits provided under the scheme include:—

(1) The payment of a weekly benefit of 15s. for men and of 12s. for women for not more than 26 weeks as sick benefit.

(2) A disablement benefit after the 26th week of 7s. 6d. per week so long as the beneficiary is incapable of work.

(3) A maternity benefit of 40s. to the wife of an insured man, which is raised to £4 when she is herself an insured person.

(4) Provision for medical benefits. This medical benefit consists of such medical treatment as can consistently with the best interests of the patient be properly undertaken by a general practitioner of the usual professional skill. It also includes the provision of medicines and of such medical and surgical appliances as are approved by the regulations issued by the supervising body, the Ministry of Health.

The employer is responsible for the payment of the joint contribution for himself and for the employee, which since January 1926 is 9d. for each employed man and 8½d. for each employed woman, but he deducts 4½d. in the former case and 4d. in the latter case from their wages. But, as shown above, the contributions in respect of pensions are now combined with these, and the actual value of the weekly stamp affixed by the employer is 1s. 6d. for men, and 1s. 1d. for women. The purchase money of the stamps, which are obtained from the post office, is paid into the National Health Insurance Fund. The State adds two-ninths of the cost of the scheme. The benefits are determined actuarially on the basis of the contributions from the employers, the workers and the State.

The administration of the scheme is carried out by approved societies and insurance committees. Approved societies consist of trade unions and friendly societies, collecting societies and special branches of insurance companies, which are to be "recognised" if they are democratically controlled and non-profit making. The medical benefits are administered by the insurance committees. These consist of local bodies representing the interests concerned, the insured persons, the doctors and the Ministry of Health. Deposit contributors, of whom there are about 250,000 are persons unwilling or unable to become members of approved societies. They are entitled to benefits up to the amount of the contributions paid in respect of them. Unlike ordinary members, they cannot draw more than that amount if their illness continues.

Most approved societies have attracted the majority of their members from particular trades. In consequence some have a high sickness rate and some a low one. The latter are in a position to give additional benefits above the normal benefits; the former suffer from deficits even when they give only the normal benefits. This system involves a certain amount of unfairness, to counterbalance which four devices for securing some measure of equalisation have been introduced:—

(1) The system of "reserve values" to allow for the age distribution of members.

(2) The contingencies fund to guard against the probability of an excess of liabilities, or deficiency on valuation of a society due to expenditure for benefit being in excess of the expected.

(3) The central fund to guard against the probability of a deficiency on valuation caused by abnormal rates of sickness due to the nature of the occupation of the members or the environment in which they live, or an epidemic such as influenza, or some other cause beyond the control of the society.

(4) The women's equalisation fund to meet the fact that women, especially married women, have a high rate of disability, principally on account of child-bearing. This fund was withdrawn and a sum added to their reserve value in its place.

In spite of these funds, the benefits obtained by clerks and agricultural labourers are very much higher than those obtained by miners, and it has been suggested that the whole of the Government grant of two-ninths should be used to guarantee all insured members the same benefits.

Proposed Amendments.—A royal commission was appointed in July 1924 to inquire into the scheme of national health insurance, and to recommend any alterations or improvements that might seem desirable. It reported early in 1926. Two reports were issued, both recommending changes and extensions, but, the minority being a good deal bolder than the majority. There was general agreement on the fundamental soundness of the system, on the need for a considerable extension of benefits, and on abolishing the insurance committees and transferring their functions to the local health authorities. The extension of benefits advocated by the majority is, however, to be made only "as and when funds are available to meet the cost." The minority report, on the other hand, rejects this proviso, and makes definite recommendations in favour of an all round extension of benefits, and especially for (a) the provision of medical treatment and attendance for children of school leaving age and for the dependents of insurance; (b) extended provision for child-bearing women before, at and after confinement; and (c) increase of the rates of cash benefit paid under the Health Insurance Acts to the present rates under the Unemployment Insurance Acts—*i.e.*, 18s. a week for men and 15s. for women.

Furthermore, the minority recommended the abolition of the approved societies system. The approved societies, they hold, are a failure. They are not democratically controlled, they are uneconomical, and they are "a hindrance to the development of a complete public health policy." The local authorities, therefore, should take their place.

Compulsory health insurance schemes are to be found in many European countries, including Germany, Austria, Bulgaria, Czechoslovakia, Great Britain, Norway, Poland, Russia, Belgium and the Serb-Croat Slovene kingdom. All the States in Australia have introduced non-contributory maternity grants. Japan introduced a scheme of health insurance in 1922, and Chile in 1924. In Poland, Russia and the Serb-Croat Slovene kingdom the territorial fund has in effect a monopoly of insurance. In Germany, Austria and Czechoslovakia the territorial fund is the leading but not the sole insurance institution. In some countries, *e.g.*, Germany, Rumania and Bulgaria, survivors' insurance, consisting as a rule of both burial benefits and pensions for their dependents, is attached to the various health insurance schemes.

Unemployment Insurance.—Great Britain was the first country to introduce a system of compulsory unemployment insurance. The National Insurance Act 1911 (Part II.), as a first instalment, made provision for insurance against unemployment in certain selected trades. The scheme was extended to include additional groups of workers by the Munition Workers Act of 1916. The Act of 1920 brought into insurance all persons of the age of 16 and upwards employed under a contract of service, excepting domestic servants, outworkers, agricultural workers and non-manual workers employed at a rate of remuneration exceeding £250 a year. Employees of local authorities, railways and certain other public utility undertakings, members of the police forces, and persons with rights under a statutory superannuation scheme may, in certain circumstances, be excepted.

As in the case of Health Insurance, the scheme is co
utory, and the stamp and book method is employed for coll
contributions. Every insured person is given an unemplo
book, on which his employer fixes a stamp weekly for the a
to be paid in contributions in respect of himself and his emp
the part of the contribution made on behalf of the workm
of course, withdrawn from his wages.

The rates of contribution, as revised in 1926, are, for me
a week from the employer, 7d. from the employee and 8d.
the State; for women, 7d. from the employer, 6d. fro
employee and 6d. from the State. These contribution
paid into the unemployment fund, out of which come all
fits and administrative expenses connected with the sche

Rates and Conditions of Benefits.—The rates and conditi
benefits laid down in the 1924 Act are that after three
unemployment, provided no suitable work is available,
receive a flat rate of 18s. a week and women 15s. a week, w
additional allowance of 5s. a week for a dependent w
husband, and 2s. a week for each dependent child. Und
Act of 1920 one week of benefit was payable in respect of
six contributions, and not more than 26 weeks of benefit
payable in one year.

Every insured person claiming unemployment benefit must
his unemployment book at an Employment Exchange when n
a claim. If the insurance officer is satisfied that no work in h
trade is available, and that the workman is bona-fide unemp
he will receive his benefit. A workman is regarded as unemplo
the purposes of the scheme when he is able-bodied, efficien
though willing to work in his own trade at the current rates of
unable to find employment because of lack of work. Benefits a
paid to those thrown out of employment through trade disputes

ables him to judge of the bona fide of applicants for bene
they are offered suitable employment and refuse it, the
is withheld.

Courts of referees of employers and employees constitute a
of appeal from an insurance officer. He in turn has an
against them to an umpire.

The total number of insured work-people in Great Britai
Northern Ireland has grown to nearly 12,000,000 and the a
receipts of the unemployment fund at the present rate o
tributions are between £40,000,000 and £50,000,000 per annu
1922 the expenditure of the fund was over £58,000,000, and
to the Treasury was incurred, most of which has since been
repaid.

The extended scheme of 1926, including also the mass of
trial workers (agricultural workers and domestic servants a
cluded), was introduced on the eve of the trade depression,
reserve funds had not been accumulated to meet the great de
Rates of contributions and of benefits have been frequently ch
the unemployment fund instead of being a creditor has be
debtor of the Treasury. The administrative checks on app
originally intended and the limitation of benefits have no
applied. In 1920 there was introduced the system of what
first called "uncovenanted" benefit, and is now known a
tended" benefit. Extended benefit is benefit allowed to unem
persons who have exhausted their "standard" benefit (*i.e.*
they are strictly entitled to in respect of their contributions)
granted under certain conditions and at the discretion of the M
of Labour. This discretion was taken away in 1924 and ext
benefit was made a right, subject only to the fulfilment
statutory conditions; but it was restored by the Act of 1925.

All this has led to unemployment insurance being decried
"dole" system. But dole is clearly a misnomer for the st
benefit. And even as regards extended benefit, the expec
always is that the recipient of it is one who had contributed
fund, and who will in the future pay the premiums against the
fit he has drawn in advance. It should be noted that the debt
Treasury is not very large, and is certain to be repaid from t
employment fund as soon as the volume of unemployment
ishes. During a period of four years from the beginning of t
pression in 1920 workers' contributions were £62,000,000; th
employers £71,500,000, and of the State £46,000,000. Thu
Exchequer provided slightly over a quarter of the total a
spent. Taking the whole duration of the scheme, the State has
and lent very little more than was originally intended by Parlia
(The Economy Act of 1926 provided for a reduction of the
grant in respect of unemployment insurance.) Nor is it a fac
the same people have remained unemployed all these four
An investigation made in 1924 into 10,000 claims showed

employment from 0 to 29 of the 125 weeks of the period covered

had done some insured employment in from 30 to 59 weeks; in from 60 to 89 weeks; and 30·5% in from 90 to 125 weeks. it is wrong to say the workman is drawing a "dole," it is clear the nature of the insurance scheme has changed owing to the sity and continuance of the industrial depression. At present heme provides for the insurance of all workers in the insured s by means of premiums paid by or in respect of those alone are actually employed and not by all those who are insured.

ce unemployment is a normal feature of industry, there is na facie ground for making benefits equal wages. There is d a large school which demands "work or maintenance" unemployed, and maintenance at full rates of pay.

t the practical difficulties of this are obvious. Generally ing, criticism of unemployment insurance takes the form ggestions for improving and strengthening the existing ne, not for abolishing it. It is proposed that agricultural ers and domestic servants should be included, that greater r should be given to advisory committees of employers mployees in its administration, that Parliament should set body with authority to advise what political and economic es will mitigate unemployment, and an interdepartmental for giving effect to such policies.

irteen years' experience has demonstrated that compulsory ployment insurance is entirely practicable, that the British ne has been conceived on right lines, that it embodies which are socially desirable, that it is actuarially sound, it is extremely elastic, and that it has been one of the signal sses of British administrative effort.

lepartmental committee of inquiry into the whole question employment insurance was set up by the British Govern- in 1925.

mpulsory unemployment insurance has now been adopted other countries. It was introduced in Italy by a legis- decree in 1919, which was superseded by a decree of 1923. ia introduced it in 1920. Queensland adopted it in 1920 Soviet Russia includes it in its Labour Code. Poland luced a system in July 1924. The Irish Free State is nuing the compulsory system it took over from England. e voluntary system of unemployment insurance supported ate subsidies previously known as "the Ghent system," peration in nine States, but the British method is steadily ng more adherents.

urance by industry.—The proposal to organise insurance dustry has attracted special attention in relation to un- yment. But there is no reason why it should not be lered also in relation to the other branches of social insur- Workmen's compensation in this country is organised in nner which ought to satisfy the advocates of insurance by try, and it is possible, if it is desired, to organise unemploy- insurance and health insurance in a similar manner. idea underlies Professor Commons' scheme for the American s.

e arguments in favour of this course and against it may be y summarised as follows:—

the burden of these social emergencies in each industry is d directly on that industry, a financial incentive will be to the employers to prevent them in each industry, and a r arrangement might even be made for each firm so as to nt them in each firm, and so lessen their burden. Why it is asked, use this obvious instrument for stabilising yment? Each industry could form one representative isation of all concerned in it, which would attempt to le with these social emergencies. Experience of working her in this way by employers and workpeople would enable to face other problems. Thus insurance by industry is to be part of the wider policy of giving the workers some of control in industry. Another argument used is the e of adjusting benefits to earnings. Unfortunately, some of arguments have little force. Thus the money incentive can be offered would be relatively so small that experience the rebate system offered under the 1911 Act to employers kept a stable staff proves that it would have little or no in inducing employers to seek means to reduce the amount of unemployment. The desire to give the workman and his employer some share in the administration of the scheme can be achieved through increasing the functions of advisory committees both of employers and of work-people. Similarly the better adjustment of benefits to wages can be achieved in other ways.

There are many difficulties in the way of this proposal. First there is the difficulty of classifying and delimiting industries, though it must be admitted that the same difficulty will have to be tackled if Whitley Councils are ever to be made really effective. Nor have suggestions been wanting how to deal with the class of floating labour, especially of unskilled labour which finds employment now in one industry and now in another. It is argued also with force that in case of decaying trades the technical process may become obsolete, but the industry continues, and it is proper for the industry to bear the burden of maintaining those who are too old to adjust themselves to the new conditions.

But there are other serious objections. Each industry would have to institute its own system of exchanges, and this would make the administrative expenses of insurance high. Besides, workmen might be tempted not to transfer from a high benefit industry to a low one even when it was economically desirable for them to do so. Labour would tend to become immobile.

Moreover, it may be doubted whether it is really unfair for, say, clerks to pay towards the cost of insuring unemployment in the coal industry. They consume coal, the trades in which they are engaged probably use it. Shipbuilding is dependent upon the iron and steel manufacturing industry, engineering, woodmaking and other industries. Most industries are dependent on coal and transport, and they all use electricity and gas. When industry has grown so interdependent there seems to be no substantial injustice in a flat rate system. (J. Co.)

VI. MEDICAL ASPECTS OF HEALTH INSURANCE

Insured Persons.—The number of insured persons in Great Britain is approximately 15,000,000. They consist of persons under a contract or service, namely all manual workers without any income limit, and non-manual workers with an income limit of £250 a year. Certain other persons, within the same income limit, who have previously been employed insured persons or who have married an insured woman, are allowed to enter the scheme voluntarily. On the other hand some employed persons who have sources of income other than their employment may be exempted, and certain whole classes are excluded from compulsory insurance because they are serving under conditions which provide benefits equivalent to those of the insurance scheme.

The Medical Service.—This large proportion of the workers of the country has been entitled not only to the cash benefits described, but, since January 1913, to such medical advice and treatment as can reasonably be expected from general medical practitioners as a class, other than in respect to a confinement. This is a very wide range; and gratuitous service even beyond this range has repeatedly been given. There are about 15,000 medical practitioners engaged in this work. Every registered medical practitioner who wishes to do so has the right to take part in the service, unless and until he be removed therefrom after due inquiry according to prescribed methods and machinery. To this provision the medical profession has always attached the utmost importance. Equally important are the provisions that every insured person has a free choice of all available doctors, that he may change his doctor at any time, and that the doctor may, with due notice in the case of illness, request his patient to seek other advice. The maximum effective number of insured persons for whom any doctor may, single-handed, make himself liable is 2,500. With a doctor of quick mind, methodical habits, and considerable ability, who devotes the major part of his time to insurance practice this number is reasonable, but in an average case where a corresponding amount of private practice is undertaken, this number is probably too large for efficient work in times of stress. In some densely populated areas where the number of doctors is relatively few and the lists correspondingly large a certain amount of complaint may at times have been justified, but these conditions are, by common consent, adjusting themselves and the service improving. In fact, the number of doctors who have lists effectively exceeding 2,000 is small, the average number of insured persons per doctor being less than a thousand.

The aim of all these arrangements is to make the conditions of insurance practice approximate as nearly as possible to those of private practice. The actual and legal relationship between doctor and patient is the same in both, the only modification of this statement (and that a small one) being that since the whole body of insurance practitioners of an area have undertaken the responsibility for attending all the insured persons of that area, each practitioner must attend any insured person in an accident or other emergency whereas this is merely an obligation of humanity in non-insurance practice. In addition, the doctor under the insurance system undertakes to give certain certificates with regard to incapacitating illness and to keep certain records and make certain reports as required by the Ministry of Health.

Effects of the System.—After 13 years of such a system it is true to say, in general, that the incidence of incapacitating illness among the working population has diminished, that whole classes of persons are now receiving a real medical attention which formerly they did not get at all, that the amount and character of that attention is immensely superior to that given under any of the old forms of contract practice, that illness is now coming under skilled observation and treatment at an earlier stage than formerly, and that the bias towards preventive rather than mere remedial treatment has been reinforced.

Good as this is it might yet be better. The existing definition of insured persons includes some—the higher-paid manual workers—who could make the necessary provision for themselves without state aid. Equally clearly it excludes many others who urgently need such aid,—*e.g.*, poor persons not under a contract of service, such as hawkers and small tradesmen. The dependents of all the lower-paid insured persons, however defined, manifestly need aid for securing adequate medical attention in some way and might well be brought within the insurance scheme. To make the required adjustments will give rise to some formidable difficulties but these should be faced and overcome. The difficulty with regard to the inclusion of dependents is almost wholly one of finance. The difficulty of including other poor persons is that of collecting compulsory contributions (not necessarily weekly) from those who have no employer. The difficulty of excluding the higher-paid of those now included is that of applying an income limit to the manual worker as well as to the clerk. These difficulties are not insuperable.

Extension of Scope of Treatment.—The extension of the scope of the medical advice and treatment available so that it shall include not merely such as can in the best interest of the patient be given by general medical practitioners as a class, but also consultant and specialist services (including dental treatment), and the advantage of pathological laboratories, would not only be of immense advantage to both doctors and patients, but would solve a good many of the minor problems which give rise to daily troubles under the existing system. The expense of such an extension as has been recommended by the royal commission on the Insurance Acts, to whose reports reference has already been made, would not be prohibitive, and experience already gained would greatly facilitate the necessary working arrangements with the medical profession. A subsequent further extension to cover residential institutional treatment, the provision of nurses, and other ancillary services would be quite practicable and would complete a national system designed to leave no one without the means of readily obtaining adequate medical attention in all forms of illness. (H. B. Br.)

INTELLECTUAL CO-OPERATION, International Institute of In Sept. 1921 the League of Nations, on the proposal of Léon Bourgeois, added to its existing technical committees International Committee on Intellectual Co-operation, ma up of distinguished scholars chosen first from 12, afterwards fr 14, different countries. Its membership included, among oth Mme. Curie, Prof. Einstein, Prof. Gilbert Murray, M. Ju Destrée and Dr. Millikan. M. Henri Bergson was elected first chairman.

The task assigned the committee was that of studying better organisation, through united international effort, literary, artistic and scientific work. The committee so became convinced that if it were fully to accomplish its task must have a permanent administrative organ to prepare its p gramme and carry out its plans. In 1924 the French Go offered to defray for the League the expenses of such organ, asking only in return that Paris be its seat. The Leag accepted the offer; and in Sept. 1925 the International Institu for Intellectual Co-operation opened its offices in Paris, at Palais Royal.

The institute is divided into seven specialised sections whi are as follows:—

General Section.—This makes a preliminary survey of all proble submitted to the institute. It draws up an annual set of internatio statistics on intellectual life and its changes in level. It studies general problems and suggestions that bear upon the internatio organisation of intellectual work.

Scientific Relations.—This section deals with specific problems international scientific organisation. It keeps in touch with important existing institutions and associations in this field, and a them to co-ordinate their efforts, encouraging the creation of n bodies where these are necessary. It follows closely the powerful still unco-ordinated activity of international scientific congresses

Artistic and Literary Relations.—These two sections study organisation, from an international point of view, of literary a artistic production. They prepared in 1926 a plan for an Int national Office for Museums. They investigate the question general protective laws for artists and works of art.

University Relations.—This section acts as a link between insti tions of higher education in all parts of the world. To this activ mmittee attached a particular importance from the first. In ey suggested to the Council and the Assembly of the League ed for an International University Information Office, since 1. In 1925 the Assembly decided to refer to the Institute for the question of a general international *entente* in matters of ion.

l.—This section deals with the legal problems raised by plans ernational intellectual co-operation. In accord with the International Labour Office, it studies the economic conditions of intellec- orkers.

rmation.—This section studies also the means by which the of intellectual work are diffused, particularly the problems of roduction and printing. It seeks to co-ordinate the activity of cal publications which treat the various phases of intellectual

institute is strictly international in character. Its officials to 20 different nations: the section for general affairs, for ce, had as its first head an Englishman; the section for sity relations a Pole; the information section an Italian; ction for artistic relations a Belgian; the section for literary ns a Chilean, a woman; the section for scientific relations a n; and the legal section a Spaniard.

staff, drawn from all parts of the world, represent the varied intellectual interests. But all of them, from the a director down, are moved by the same desire: to seek in ndividual problem submitted to them, with all the exactnd modesty of experts who understand the clear limitaof a given task, the methods best adapted to reconcile the ts of each nation with those higher interests of the mind overn the broad sphere of intellectual life.

ELLIGENCE, ANIMAL (*see* 14.680).—A broad distinction is only drawn between instinctive and intelligent behaviour nals, and it is necessary therefore to frame some definition t is meant by intelligent action. In this matter McDougall writes as follows:—

> definition and demarcation of instinct and intelligence have uch debated of recent years; but no general agreement as to cise use of the words has yet been reached nor can be reached greement as to the nature of the facts denoted shall have been ed. But the great majority of all parties would agree that we operly call "instinctive" those actions of animals which seem urposive (*i.e.*, exhibit the marks of behaviour) and which are ned by any animal independently of previous experience of situations. . . . Intelligent action, on the other hand, is lly defined as one which seems to show that the creature has d by prior experience of similar situations, that it somehow to bear its previous experience in the guidance of its present Instinct (abstractly conceived and with a capital letter) is or inborn capacity for purposive action; intelligence is the ty to improve upon native tendency in the light of past exce (pp. 70, 71). (*See* PSYCHOLOGY.)

e authors, particularly Fabre and Bergson, have attempted ke the distinction between instinct and intelligence an te one, attributing to instinctive animals psychical powers almost miraculous kind. This view is not widely accepted se who have studied most carefully the manifestations of ct. The fact is that neither form of behaviour appears ." Glimmerings of intelligence may be awakened in even ost stereotyped of instinctive actions, and intelligent is often merely an extension and embroidery of instinctive iour. Their resemblances are more important than their nces—both are forms of purposive activity, adapted to ng some end connected with the maintenance and conce of life, and finding their driving force in the primary c impulses of the living thing (E. S. Russell, *The Study of Things*, 1924). The contrast is between the accuracy and nical undeviability of instinctive behaviour, inborn in the l, and the probing tentativeness of intelligent action, seeks to modify in the light of individual experience and pt to changing circumstance the blind impulsions of in-

Definition.—If we adopt this broad criterion—modifiability of behaviour in relation to past experience—we may say that intelligence in this sense is practically coextensive with animal life, for even the Protozoa alter their mode of reaction if their first response fails, and show the beginnings of "learning by experience" (Jennings 1906).

Animal Behaviour.—Since about 1900, much attention has been paid to the study of animal behaviour, both by zoologists, who have studied particularly the sensory physiology of animals and have tried to analyse their behaviour in terms of tropisms and reflexes (see, for instance, Loeb 1919), and by professional psychologists, who have studied particularly the intelligence of the higher animals (and some of the lower) by means of highly developed and ingenious mechanical contrivances, such as puzzle boxes, mazes, and the like. Nor should one omit to mention the good work done by field naturalists like Beebe and Miss Frances Pitt upon the behaviour of animals going about their ordinary business in their natural environment.

Experimental Work.—With respect to the question of the intelligence of animals, particularly of the higher forms, in the works of Yerkes, Thorndike and Hunter, and in the useful general account by Miss Smith (1923) and Kafka (1922), details are given of elaborate experimental researches carried out on habit-formation, the processes of association, sensory discrimination and so forth. Generally speaking, these experiments afford little evidence of anything like reasoning power even among the higher vertebrates. Learning appears to be a rather mechanical process, in which little intelligence, in the ordinary acceptation of the word, is shown. The objection may, however, be fairly made to many of these experiments that the animals are placed in unnatural conditions which inhibit them from developing the full range of their capacities. Of quite special interest in connection with the general problem of the intelligence of the higher animals are the experiments and observations of the distinguished German psychologist Köhler, on a number of chimpanzees which were kept at an experimental station in Teneriffe under very easy conditions of captivity. The apes had the run of a large open-air enclosure, and were allowed to develop a normal social life without undue interference.

The tests applied were simple and based upon a thorough and sympathetic knowledge of their normal behaviour. They consisted generally in setting the animal the problem of attaining a coveted object, say an attractive fruit, which was placed beyond their reach—outside the bars of the enclosure, for instance, or suspended high up from its roof. The use of a stick, or of anything which might function as a stick, to draw the object within reach was grasped at once, and one ape learned to join two sticks together if both were too short. The use of a short stick to draw within reach a longer stick with which to attain the objective also presented little difficulty to the more gifted individuals. Many learned to pile one box upon another in order to reach a high object—the best effort in this direction being a (somewhat ramshackle) construction of four boxes one on top of the other. What was really striking and significant about the experiments, however, was that the apes did not come by the solution of their problems by a random method of trial and error, but by suddenly grasping the situation after a longer or shorter period of puzzlement, and applying a correct solution straight away. Köhler argues very convincingly that these apes must possess a certain power of insight or judgment of the visual situation as a whole; their problem-solving is accordingly a very different thing from the gradual beating out of a solution through undirected effort and chance associations, which is found in the experiments of Thorndike and his school.

Thinking Animals.—In conclusion, a brief reference may be made to the so-called "thinking animals"—the Elberfeld horses, the Mannheim dog and others—which by means of signs can apparently spell out answers to questions and give the solution of mathematical problems. While the phenomena are not yet fully explained, there is a general consensus of opinion that these animals do not really reason, but are in some way guided unconsciously by their trainer—and perhaps by the spectators also. On the question of trained animals in general the works of Hachet-Souplet should be consulted.

INTELLIGENCE, HUMAN (*see* 14.680).—This name is among the most widely used and hotly disputed in the psychology of to-day. To call any one "intelligent," or one of its synonyms, as "bright," "sharp," "brainy," or one of its antonyms, as "stupid" or "dull," is a universal custom, alike in scholastic work, industrial management and familiar conversation. The word has also long played a very conspicuous part as denoting the alleged distinguishing privilege of the human species.

But by far the greatest excitement has arisen from the claim raised that any person's intelligence can actually be measured by means of mental tests. After some important theoretical work by others (see later on), the first great practical success with these tests was effected by Binet and Simon in 1905. The test-scale devised by them was applied in a great many schools, and it still to this day—with radical revision—continues to be the standard scale, at any rate for young children. But the most startling achievement of the testing (chiefly by means of another scale) was its application to nearly 2,000,000 men of the American Army in 1918. The results proved to be so useful as to elicit a very high eulogy from the American Secretary of War. Since then, the application of one or other of the multiplying scales to schools, universities and other institutions has in most civilised countries extended so widely as to comprehend the greater part of the juvenile population.

What the Tests Measure.—Despite all this outward success, however, there has sprung up much and vehement criticism. The main source of trouble has been that those who are making such mental measurements cannot agree as to what they are measuring, or even as to what they ought to measure. For example, some think that intelligence should include memory, and they therefore introduce into their scales a certain amount of memorizing. But other testers rigidly exclude any such thing. Many—as Binet himself—first declare that memory does not appertain to intelligence, and then nevertheless proceed to make memorizing a conspicuous part of their actual tests. Similar confusion and inconsistency reign about imagination, about attention and about sensory perception; both theory and actual practice are at loggerheads as to whether the tests should include any or all of these. Some authorities go the length of wanting intelligence to embrace, not only the co-ordination of ideas, but equally that of movements. In short, this state of affairs can without exaggeration be called one of complete chaos.

Historical Development.—The key to understanding the situation appears to be supplied by historical considerations. With the old Latin-writing philosophers, intelligence (intelligentia) meant the using of the intellect (intellectus); and the latter word was their rendering of the still older νοῦς. This and sensory perception (αἴσθησις) were regarded as the two great faculties
of man. The sensory perception was his evil genius, tri
him with all manner of appearances and illusions, whils
intelligence opened his eyes to the real truth. But in cou
time other philosophers and psychologists brought into this
ory various complications. By some a further faculty of me
was added on. By others, imagination was honoured in
way. By yet others, attention, and even movement. More
alongside of this tendency to set up various faculties outsi
intelligence, and thus curtail the sphere of the latter, ther
occurred some change in the opposite direction of expandi
sphere; in this way, it was sometimes made to comprehend
sensory perception,—which had originally been regarded
very antithesis.

With lapse of time, these diversified doctrines, each
distinct as handled by the school which advocated it, beg
percolate down to wider and less instructed circles. In so
they became more and more intermingled. What the
eventually evoked in the mind of the man in the street—
too nice about logical consistency—was a confused reverbe
of all the different views. The last phase of the history was
modern psychologists—instead of properly moulding clear
for themselves—complacently took over this old notion
telligence from the popular usage. All went well enough
they began to examine what they had really got into their h
which proved to be a word with so many meanings as practi
to have none.

Definitions.—To cure such equivocality, the natural c
would seem to be a definition. Accordingly, there have
many attempts at this. Most adherents appear to have
gained by the proposal to define intelligence as *conscious a*
ability to new situations (W. Stern). But, unfortunately, no
could be more equivocal than the term "adaptation" i
Admittedly it means a change that fulfils some purpose; b
to whose purpose, and of what kind, nothing is usually
widely divergent interpretations are possible, and actually g
The next most favoured definition has been as *the capaci*
learn (Buckingham). But this "*learn*" is at least as bad a
"adapt." By the dictionary, it signifies the acquirement o
skill or knowledge. But most advocates of this definition
dently mean neither the acquiring of skill nor many for
acquiring knowledge (*e.g.*, memorizing). What they do me
left unstated.

Eduction.—Another interpretation of intelligence has
extensively advocated, namely, as the power to perform wh
called "*eduction*" (Spearman). This is said to have two f
of which the first consists simply in the perceiving of rela
between any two given ideas (taking "idea" in its bro
possible sense). The other form is when an idea and a rel
are given, and from these two there has to be found the co
tive idea. Now, eduction in this sense does escape the ba
equivocality. Also, it has shown itself to be a power of p
mount importance, especially as contrasted with the only o
possible ways of obtaining ideas (namely, by sensation an
reproduction). Moreover, this eduction does seem to ind
something which most persons will admit that they, in usin
word intelligence, are really "driving at."

Difficulties of Measurement.—Any way, even after fitting
term intelligence with the most irreproachable definition t
still remains a great difficulty in accepting the far-rea
claims to have *tested and measured it.* The rub consists in
fact that such a mental power—whichever of the definition
may choose for it, even the last—always admits of being su
vided; hence, a separate measurement would seem to be in
pensable for each subdivision.

Thus, Binet himself admitted that the intellect breaks up
several different faculties, and wrote about these: "The me
faculties of each subject are independent and unequal; wi
little memory there may be so associated much judgment. .
Our mental tests, always special in their scope, are each ap
priate to the analysis of a single faculty" (*Les idées mode*
sur les enfants, Paris, 1910). If he thought this, then wh
he not, why do not his followers, measure each of these indep

culties, memory, judgment, etc., one by one? Furthermore, faculty itself can be divided up. For instance, why should person have a good memory for some things and a bad one thers? And if we push this argument far enough, the red measure- ments would seem to become infinitely numernd therefore incapable of ever being really executed.

sts by Samples.—For this difficulty of measurement there been only two solutions so far proposed that deserve serious deration. The first and most widely known—especially iated with the name of Thorndike—is that the current measure *a representative sample* of the subject's abilities. his view, plausible enough at first sight, does not bear scru- In order to pick any genuinely representative sample of ing, every portion of this must be represented fairly (*see* c). For example, the sampling of a field of potatoes would r from representative if we selected many from some parr areas and few or none from others; we ought to divide the into equal parts, and pick an equal number from each. But e case of mental abilities there seems to be no possible od of settling what parts are really equal.

st Scales.—In a well known test-scale (Yerkes), judgment is to supply three test-elements, whereas ideation supplies one. On what conceivable ground can we settle whether ent is or is not three times as large a faculty as ideation? r test-scales no less arbitrarily reverse this ratio. As for cale of Binet, this even within itself gives the most widely gent ratios between different test-elements when the scale plied to children of varying ages.

efficients of Correlation.—There remains the other serious pt at solution (Spearman). If a large number of people ubmitted to two tests, the degree in which the same persons to excel in both cases can be expressed numerically by is called a coefficient of correlation. If several tests are there will of course be a correlation for each different pair sts. Now, proof has been given that, when the magnitudes these correlations satisfy certain mathematical conditions, and only then the score of each person in each test can be ed into two factors, of which the one has always the same (for the same individual), whereas the other varies independently from one test to another. These two factors have been olised as "g" and "s" respectively.

asurement of "g".—Further evidence has been furnished with suitable tests (of "eduction," *see* above), these mathecal conditions are actually fulfilled. It is easy to see, then, if the tests are made sufficiently numerous, the independent s of the "s" must tend to neutralise one another on an ge, leaving the "g" as a value uniformly characteristic of ndividual. This "g" it is that has actually been measured re or less accurately—by the mental tests now in usage. It t in the least equivocal, for we know exactly under what itions it always occurs. But there still remains the task of preting it; herein it resembles electricity, which was meas- with great exactitude long before its intrinsic nature was approximately understood. In both cases, too, the illumin does not arrive in a flash, but accumulates gradually.

the present moment, "g" seems to be best conceived as a n's "general mental energy," whereas the "s" varying test to test represents so many different mental "engines," any of which (alternatively) the energy can be switched. is "g," then, the "intelligence" receives yet another pos- interpretation. Here, it would not consist in any entire ty whatever, but constitute a factor that enters into multious (eductive) abilities. But whether or not the "g" be sted with this title of intelligence, it at any rate furnished original inspiration for the miscellaneous mixture of testents that currently claim to measure it (in this respect, t appears to have been an unconscious borrower). Also, it lies such tests with their sole genuine justification.

BLIOGRAPHY.—This is widely dispersed, for the most part in the y journals specially devoted to psychology. A general account be found in *The Nature of Intelligence*, by C. Spearman (1923).

(C. SP.)

INTELLIGENCE, MILITARY AND NAVAL.—Under this designation may be considered the work of obtaining, collating, interpreting and distributing information, in peace and war, about foreign powers, the countering of foreign powers' efforts to obtain intelligence, and the organisation which performs these duties. Information as to actual or potential enemies, allies and theatres of war, has always been required and obtained by governments and commanders in the field; the employment of spies, the questioning of prisoners, date from the earliest times in history, but never have the scope, and what might be termed the technique of military intelligence, reached such a high degree of development as in the World War.

I. INTELLIGENCE IN PEACE TIME

In time of peace, the relative military power of a nation with regard to other foreign powers, and in particular to its immediate neighbours, necessarily affects its foreign policy. Every government therefore maintains an intelligence system, which generally forms a section of the headquarters staff of its military forces (known in most countries as the General staff), for the purpose of:—

(*a*) Providing its Government with all necessary information regarding the military power of foreign nations;

(*b*) Devising means whereby, in case of war, all essential information concerning the enemy, allies and theatre of war may be placed at the disposal of the commander and troops, and the supply of further information continued throughout the campaign;

(*c*) Preventing the acquisition of information by the enemy.

Type of Information Required.—The fighting power of a nation can only be gauged when accurate and detailed information is available on certain factors, the most important of which are the organisation, strength and power of expansion, armament, tactics and morale of its armed forces, the characteristics of its leaders, its defensive works and fortresses, its communications, such as road, railway, waterway, aerodrome, cable, telegraph and wireless telegraphy systems, its physical and political geography, climatic conditions and economic and industrial resources in relation to military requirements. This information also enables the General staff to prepare, and keep up to date, plans for offensive and defensive operations, together with estimates of the forces required for their execution against any power or combination of powers, with which the particular power, either alone or in co-operation with other powers, might be brought into conflict.

Sources and Value of Information.—The main sources from which information is derived in peace time are statistics and economic data obtained from foreign government publications, from the Press and technical works, foreign training manuals, military and geographical publications and from information procured by the Secret Service.

When war breaks out, this intelligence system provides the commander and troops about to take the field with maps and all available information regarding the theatre of war, the armed forces and military resources of allied and hostile powers, with their special characteristics; this information forms the basis of the plan of campaign, but requires to be supplemented with information concerning the enemy's mobilisation, concentration and order of battle in general. For this purpose preparations must be made beforehand and an intelligence organisation provided for the troops in the field; the intelligence section therefore lays down the foundation of the intelligence organisation required in war and makes arrangements for expansion by training the special personnel required.

II. INTELLIGENCE IN WAR TIME

In war, the greatly increased activities of the home or headquarters intelligence service are mainly directed to areas outside the theatre, or theatres, of operations. In the latter, the armies in the field are provided with intelligence services of their own, who form an additional source of information for the home intelligence service, which is responsible for the further collation and distribution of the information thus received.

Field Organisation.—In the field, the intelligence section of the General staff collects and collates all information regarding the enemy's forces and intentions and the theatre of war, supplies to the commander, staffs and fighting troops all information which will assist them in preparing and carrying out plans for the defeat of the enemy and endeavours to prevent the acquisition by the enemy of similar information. To be of practical value, the information supplied must be relevant, furnished in time to be of use and in such form as will admit of its immediate application by those concerned. These conditions require the closest co-operation and mutual understanding between the intelligence and operations sections of the General staff. The developments, technical and otherwise, of modern warfare have placed at the disposal of the intelligence section many resources for collecting information which were not available prior to the 1914–9 campaign. Intelligence in the field has become a large and intricate organisation, the varied and complex nature of whose duties necessitates the employment as assistants to the General staff proper, of a large number of highly trained specialists.

Knowledge of the enemy's intentions is of supreme value to a commander, and the intelligence section should therefore possess throughout the campaign early, accurate and continuous information regarding the enemy's "order of battle," his movements of men and war material, his tactical method, armament and equipment, the organisation of his defences and rear services, the topography of the theatre of war. The relative value of these different classes of information varies with circumstances; the character of the operations may change at any moment from open warfare to stabilised warfare, or the reverse; an intelligence service must therefore be elastic both in method and organisation. Method, accuracy and speed are essential for the collection, reception, transmission and collation of information, but this work is of no value unless timely deductions can be made from the evidence available. The making of deductions, appreciations and forecasts both as to the probable action of the enemy and the prospect of successful operations undertaken by its own troops is the most important duty of an intelligence section. Its true function, in fact, is to represent the operations section of the enemy, for broadly speaking it provides all information concerning the enemy, the allies and the theatre of war, whilst the operations section provides similar information regarding the troops of its own army.

Scope and Nature of Information.—Information regarding the enemy's "order of battle" is of paramount importance. It includes the organisation, composition and strength of hostile formations, the direction of their initial concentration and subsequent movements, their distribution, morale and fighting efficiency, the characters of their commanders, methods of recruiting and man-power available to replace wastage. The identification of units is the foundation of all "order of battle" intelligence. Movements of men, supplies and material on a large scale normally portend some important development or a change of the enemy's plans, but as they must take place along organised lines of communication are difficult to conceal. Detailed knowledge of the enemy's system of communications and means of transport is therefore essential; the capacity of railways, quality of roads, navigability of waterways at different seasons, system of aerodromes and auxiliary landing grounds must be carefully studied if reliable conclusions are to be arrived at regarding the size of any movement and the time required for its execution.

Full information regarding the tactics and armament of the enemy at the outbreak of war is usually available by the study of his peace training and organisation; but his methods of employing troops and their weapons in the field must be followed very closely in order to discover new developments as early as possible. In the World War full knowledge of each others' pre-War tactics and armament was possessed by the opposing armies, but almost from the beginning of hostilities modifications and new ideas were introduced, which frequently provoked counter measures. Instances were the employment of poisonous gases, flame and gas projectors, "storm troops," Stokes mortars and tanks. All the economic resources of a State may be requi
meet the strain of a prolonged campaign, and accurate k
edge regarding these resources is one of the means of gaugi
enemy's staying power.

Sources and Means of Collecting Information.—The main so
of information are prisoners, deserters, local inhabitants, cap
documents and material, land reconnaissance and observa
hostile signalling communications, air reconnaissance and
tography, the enemy and neutral Press and agents; the pri
agencies for its collection are the fighting troops, the signal se
aircraft and secret service. The information, whether po
or negative, acquired by contact with the enemy is that on
every commander mainly relies in making his tactical
Hence, to keep the enemy under such close and continuou
servation that he can make no movement without being det
is the primary object of all reconnaissance, whether o
ground or from the air.

Ground reconnaissance may be purely topographical, *e.g*
acquisition of unmapped information about the ground; it
be tactical, *e.g.*, to discover the enemy's positions, the str
and distribution of his defences, his tactics, movements an
tentions; or for the purpose of obtaining "identifications,"
information about the hostile troops in line, their morale, a
ment and equipment, by the capture of prisoners or docum
These objects are achieved by sending out mobile troops, p
or raiding parties, or by observation from fixed points. The
may be visual or instrumental.

Visual observation for intelligence purposes is an orga
system for the observation of all enemy activity within the
of vision of its observation posts by trained observers pro
with a special equipment of maps, telescopes, periscopes,
its elements being generally so placed and co-ordinated tha
exact location of the enemy activity recorded can be fixe
intersection, *e.g.*, "flash-spotting." Instrumental observa
is mainly automatic, by instruments disposed to receive, t
form and transmit impulses from outside, *e.g.*, sound-ra
installations, electrical listening posts, wireless interception
direction-finding apparatus.

Air Reconnaissance.—Information from the air is derived
balloon observation, aeroplane reconnaissance and air ph
raphy. The development of air reconnaissance and ph
raphy has to a great extent revolutionised the whole servi
military intelligence in the field; not only are aircraft capab
assuming the duty of strategic reconnaissance, but the ca
has made it possible to obtain, particularly in position wa
a far more detailed and exact knowledge of the enemy's sy
of defence, communication and supply than has ever been
sible before. The principal weakness of air reconnaissance
photography, however, lies in their necessary dependence
the weather.

Balloon observation is used principally for the observatio
movement by road, railways, and in back areas, of defence wo
the location of hostile batteries and the observation of h
artillery activity. Aeroplane reconnaissance is used at the begi
of a campaign to locate the direction of the enemy's main concen
tion, to report on the movements and activities of the ene
troops; and subsequently to supply information on the la
tactical dispositions, the construction or destruction of bridges,
construction of new defences, etc.

Strategical reconnaissance involves long distance reconnaissa
extending frequently to distances exceeding 100 m.; they are us
carried out by single aeroplanes flying at such an altitude a
minimise the chance of hostile interference; at this height, m
ments of troops on the ground are unnoticeable, and the inform
gained is largely confined to reports of railway movements, act
at important junctions, formations of large camps, etc. It is o
necessary to fly at medium altitudes and to employ formatio
aircraft capable of dealing with air opposition, to obtain mor
tailed strategical information. Tactical information can only b
tained in sufficient detail by aircraft flying low (close reconnaissa
who can be expected to distinguish troops in the open and artill
in action, can dive near enough to the ground to clear up a
nite point, such as the existence of a machine gun emplacement
whether a trench system is occupied or not.

Photography forms an essential part of all air reconnaiss
Even in the cases of reconnaissances at high altitudes photogra
may be expected to show road movements, tracks, camps,

, battery positions, dumps, hospitals, light railways, telegraph
and other signs of military activity, while in the case of close
naissance carried out at lesser altitudes, photographs taken in
rable weather enable experts to discover the smallest details
enemy's defences.

III. THE SECRET SERVICE

e secret service supplies information regarding matters
d the enemy's front, and in his home territory, including
gth and location of reserves, rear defences and lines of com-
cation, internal conditions in the enemy's country and the
of his resources in man power and material.

ret Service Methods.—The methods employed in this branch
telligence work can only be referred to in general terms.
lly speaking, its duties are:—

Offensive, in the acquisition of information by means other
those described in Sections I. and II. above;
Defensive, in the prevention of the acquisition by foreign powers
ormation regarding the forces of its own country.

e duties of the offensive section, to which alone the name of
t service is popularly applied, are similar in peace and war,
var increases the importance, and with it the difficulties and
ers of the work of secret agents or spies.

ents work *à poste fixè*, on definite missions or on general roving
nissions; they penetrate into enemy territory through the ports,
guise of peaceful neutrals armed with all the necessary papers,
t there by other means, which in war include penetrating the
y lines, either in uniform or mufti, during the progress of an
n; landing behind them from an aeroplane or free balloon or
ng a frontier guarded by sentries and electrified wire. False
s, disguises, secret ink and all the other tricks beloved of the
ovel may form part of their equipment, but in practice, the
dangerous and efficient spy is the least sensational in his meth-
when arrested he invariably has all his papers in order, and is the
plausible person alive. An espionage system in war involves the
oyment of many thousands of men, women and even children
grades of society and of all professions: post-boxes, smugglers,
s, train watchers, pigeon men, couriers, runners, etc. All have
part to play, and that part, far from being ignoble, may be, if
ted by patriotism, as noble, as dangerous and as heroic as any
d in the armies in the field.

ntre-espionnage.—The duties of the defensive section, popu-
described as *contre-espionnage*, are also the same in peace
ar, but the machinery and methods vary when carried out
ome territory, in occupied enemy or allied territory.

e *contre-espionnage* section in home territory commands in
and war all the assistance of trained police, censorship, port
ol, hotel registration, the erection of arbitrary barriers such as
bited areas and of all the preventive measures which are the
ome of years of experience in combating enemy espionage under
onditions. In occupied territory, intelligence in the field equally
s these powers, and, in addition, the arbitrary powers of an
oying army, but the whole population is potentially hostile. In
l territory the difficulties are greater, as it is the ally who con-
in his own home territory all the real preventive machinery.

ne object of *contre-espionnage* is, first and foremost, preven-
Information may be gained by the enemy's agents equally
one's own troops and from the civil population; the former
sell or convey information deliberately, but will more prob-
convey it to the enemy's agents through indiscretion.

Leakage" may occur in several ways; gossip about impending
ations among the troops, especially when on leave and out of
ine; indiscreet conversations, messages and misuse of code on
telephones and telegraph; marking of railway trucks, transport
billets, with inscriptions giving identifications of units; indiscre-
in correspondence; careless handling of confidential papers and
s; taking orders, codes, books, papers of any kind, even private
rs into the front line; wearing of badges and numbers, which
al identifications and in many other analogous ways.

he *contre-espionnage* section is also responsible for the con-
of the civil population. This involves the control of circu-
n, of the use of telegraph, telephone and other methods of
munication, which might be utilised by enemy agents.

(T. G. G. H.)

TELLIGENCE TESTS.—An intelligence test or intelligence
nination is an instrument to measure the amount of intelli-
e shown by a human being or a lower animal. The instrument consists of a series of questions to be answered, or directions to be followed, or things to be learned, or intellectual tasks of any sort to be performed. Intelligence or intellect may be defined as the ability to perform intellectual tasks; and an intelligence test is a specially instructive sampling of such tasks.

Sample Tests.—The tasks shown below are representative of those used in standard intelligence tests.

"Show me your nose. Put your finger on your nose." Same with eyes, mouth and hair. Three responses out of four must be correct.

What is the difference between: (*a*) Laziness and idleness; (*b*) Evolution and revolution; (*c*) Poverty and misery; (*d*) Character and reputation.

Repeating three digits. After some explanation and practice, the person tested is asked to say 6-4-1, then to say 3-5-2, then to say 8-3-7. The test is passed if one series out of three is repeated without error, after a single hearing.

Repeating six digits reversed. The series used are 4-7-1-9-5-2, 5-8-3-2-9-4 and 7-5-2-6-3-8. The test is passed if one series out of three is repeated without error.

Tom runs faster than Jim. Jack runs slower than Jim. Which is the slowest of the three?

John said: I heard my clock strike yesterday, 10 minutes before the first gun fired. I did not count the strokes, but I am sure it struck more than once, and I think it struck an odd number."

John was out all the morning from the earliest hours; and his clock stopped at five to five the same afternoon.

When do you think the first gun was fired?

After some explanation and practice, the person tested is asked to "Finish what I say." At night you sleep in . . . . Mary has a ring on her. . . . You wear gloves on your. . . . You wear a . . . on your head.

The . . . of character is its ability to . . . liberty . . . from licence. Judicial decisions are of . . . or less authority as precedents . . . to circumstances.

A person who has been tested in respect of an examination consisting of from 50 to 200 such tasks may be given a score, and so be put in comparison with all others who have been tested with the same collection of tasks.

Intelligence Quotient.—Subject to certain limitations, the score may be expressed in terms of a mental age, that is, the age at which the average child is able to attain it. Thus if John Doe, aged 12·0, scores 118 in the national intelligence examination, and if the average child of age 13·1 attains a score of 118 in this examination, John Doe has a mental age of 13·1 years. John Doe's intelligence quotient, or I.Q., is his mental age × 100 divided by his chronological age, that is $\frac{13{\cdot}1\times 100}{12{\cdot}0}$, or 109.

This form of statement is useful for individuals whose scores are not higher than those made by the average child of 14, and whose chronological ages are not over 18. For higher levels and later ages the method is of doubtful value.

The score may also be expressed in terms of the percentage of some defined group who would attain lower scores than it. Thus, if 71% of persons aged 12·0 score lower than 118, and 29% score higher, in the national intelligence examination, John Doe may be recorded as in the 71 percentile for his age. This method is especially useful in the case of the higher levels of intelligence and adult ages. A more refined measure of this type expresses any individual's score as a plus or minus deviation from the average for some defined group in terms of the variability of that group as a unit. The technique by which this is done is beyond the scope of this article.

Systems in Use.—There are 30 or more such intelligence examinations now in use. Some, like the Pintner-Cunningham Primary Tests, are adapted to measure very young children aged two to five years. The National Intelligence Examination is designed to fit the intellects of the level of ordinary children from nine to 15. The Terman Group Test is especially suited to measure young people from 14 to 20. Some, like the Thorndike Examination for High-School Graduates, are adapted to measure gifted adults. Some, like the Army Group Examination Alpha, require an ability to read and write; some, like the Binet, are given orally; some, like the Army Beta, are largely independent of language. Some, like the Otis group Intelligence Scale, measure chiefly intellect as it operates with words and numbers and abstract relations; some are more concerned with information about things and persons. In some, the speed of response counts a great deal in determining the score made; in others, it counts very little, the time allowed being sufficient to permit almost everybody to do almost everything of which he is capable.

Historical Development.—Existing instruments for measuring intelligence developed from three roots: the tests of sensory acuity, memory, attention and the like devised in the early history of psychology; the interview, as of physician with patient or employer with candidate for employment; and the school examination. Galton, Cattell and Binet were pioneers in this field of psychology. Sir F. Galton's *Inquiries into Human Faculty* (1883) presented the general problem of the measurement of individual differences; and he soon thereafter set up in the South Kensington Museum in London a laboratory where any person could be measured in a series of physical and mental traits. Under the influence especially of Cattell, many short examinations or "tests" of special mental powers were devised and rather widely used in the United States from 1890 on. Important work was done by Kraepelin and Ebbinghaus in Germany. An eminent French psychologist, Alfred Binet, using the general form of an interview between physician and patient, enriched by suggestions from psychological tests proper, produced in 1905 what may be called a standardised interview, consisting of 30 questions and tasks, many of which were chosen from the tests of special powers now familiar to all psychologists. This "metric scale of intelligence" was further improved and divided into age levels in 1908, and finally revised in 1911. Many variations of it have been used in different countries.

While Binet was developing a scientific interview and record and score, various psychologists in America were testing children in groups by means of printed collections of tests. The next step was the arrangement of such a collection in a standardised unitary examination, after the general plan of written examinations in school subjects. One of the earliest and by far the most influential of such arrangements was the group examination Alpha prepared in 1917 for measuring recruits in the U.S. Army. This examination was taken by nearly 2,000,000 men, large groups (sometimes over 1,000) being sometimes examined at one time and place.

Modes of Use.—Since then, intelligence examinations have increased rapidly in number, have become diversified in nature, and have been much improved in respect of convenience in giving and scoring. They are widely used, especially in the United States, as an aid in the proper grading and classifying and treatment of school children; and in studies of special groups such as defectives, delinquents and dependents. The methods used in conducting intelligence examinations are also being applied to examinations in school subjects, producing the so-called "new-type" examinations and educational achievement tests. At least 1,000,000 such examinations were made in the case of school children alone in the year 1925. Some of the leading American universities require an intelligence examination as a part of the general admission requirement.

In spite of notable improvements during the last 20 years, existing instruments for measuring intelligence suffer from serious deficiencies. Just what they measure is not known; how far it is justifiable to treat the scores by ordinary arithmetic is not known; just what the scores signify concerning intelligence in general is in dispute. An intelligence examination is still a more or less undefined collection of tasks, its score is still a somewhat arbitrary summation of credits, and the correspondence of the scores to the abilities which they purport to measure is still far from perfect. Psychologists are working to supply these deficiencies, seeking to replace the undefined collections of tasks by tasks rigorously defined in nature and graded by a true scale of intellectual difficulty, so that the score may mean the precise height of intellectual difficulty which the person in question can master (*see* EXAMINATIONS).

INTERNAL COMBUSTION ENGINES.—For the evoluti the internal combustion engine from its first appearance in tical form as the Otto Silent Gas Engine of 1876 down t year 1910 *see* the articles GAS ENGINE and OIL ENGINE (1 and 20.35).

The essential feature of all internal combustion engines i exceedingly rapid combustion, or explosion, within the wo cylinder itself, of a mixture of air and some inflammable g vapour; great heat is liberated by the explosion and this c a correspondingly great rise of pressure in the working mi which then drives the piston forward, so performing the wo stroke. All present-day internal combustion engines op upon either the Otto (de Rochas) four-stroke, or upon the (type two-stroke cycle; in the first of these only one wo stroke, per single-acting cylinder, occurs in every alternate lution at the crankshaft, while in the second a working s is obtained in each revolution.

The types from 1910 are conveniently referred for descri purposes to five groups, viz.:

Large gas engines (exceeding, say, 400 H.P.).
Medium gas engines (less than about 400 H.P.).
Engines using heavy oils as fuel.
Engines using light oils as fuel.
Special types.

Large Gas Engines.—The changes in this class between and 1925 consisted almost wholly in improvements in deta the extended employment of waste substances as fuel for th producers; in the employment of high-tension electrical met of ignition; in better cooling and governing arrangements, The increase in the number of gas engines of the inverted-v cal multi-cylindered, quick-revolution, floor-space-saving ty also noteworthy.

The large, horizontal, slow-speed type is illustrated by Nürnberg, or M.A.N., four-stroke, single-cylinder or tandem twin-tandem, double-acting engines commonly using as producer gas, coke-oven gas, blast-furnace gas or natural One notable installation in Japan includes four horizontal t dem double-acting, single-crank, four-stroke cycle engines, e direct-coupled to a 1,500 kw. alternator.

The cylinders are $47\frac{1}{4}$ in. diameter and the stroke is $51\frac{1}{8}$ each engine is capable of developing 2,500 H.P. at 100 r.p. the fuel used is Mond producer gas, the producers (with ammo recovery) yielding 111,000 cu. ft. of gas per ton of Japanese c These engines are very massive; each cylinder weighs 25 to the fly-wheel 100 tons (see fig. 2 on plate) and the compl engine about 400 tons. At full load the consumption of fuel about 1·8 lb. per kw. hour. Among other similar installation that at the San Mateo power station of twin-tandem, dou acting, horizontal four-strokers, each unit containing four c inders, 42 in. diameter x 60 in. stroke, and developing 5, B.H.P. at 90 revolutions per minute. The M.A.N. type, thou large and heavy and occupying considerable floor space, is ceedingly reliable and economical; thus, a 2,000 H.P. M.A. engine using blast-furnace gas ran day and night during months; in 13,870 consecutive hours the engine actually r during 13,687 hours, *i.e.*, 98·6% of the whole time; and the st pages were due not to the engine but to repairs necessary to t blast furnace. A third noteworthy large installation has 17 ho zontal, twin-tandem, double-acting, four-stroke M.A.N. ty engines, capable of an aggregate output of over 50,000 hor power.

Large Two-stroke Gas Engines.—The large two-stroke Cle cycle engine has also found considerable favour in the horizont designs at Koerting and Oechelhauser. (*See* 11.499–500.)

rting.—The double-acting, two-stroke Koerting engine,
s characteristic very long water-cooled piston and central
exhaust parts has been built in England in units of up to
H.P., with cylinders $37\frac{3}{8}$ in. diameter x 63 in. stroke, run-
t 70 r.p.m., while on the continent of Europe units giving
H.P. per cylinder 42 in. diameter x 55 in. stroke x 80–90
have appeared; the Koerting type engines installed at
o aggregate 40,000 horsepower. The American Worth-
Co.'s first large inverted-vertical, cross-head-type, double-
, two-stroke engine, built in 1924, using oil as fuel in the
manner, employed the Koerting type piston.

elhauser.—The manufacture of this type of single-acting,
roke, opposed-piston, open-cylindered, internal combustion
has been greatly stimulated by the ingenious arrange-
adopted by Mr. Fullagar, who has retained the character-
dvantages of the type and has obtained in addition marked
ny in space, weight and production cost by associating
echelhauser cylinders side by side with cross-over piston
ng rods, as his power unit. The Fullagar engine is built in
nd mainly for marine purposes, using heavy oil as fuel in
iesel manner.

tical Gas Engines.—The considerable bulk and weight of
rizontal slow-revolution large gas engine has caused much
ion to be devoted to the faster-running, multiple-cylin-
, inverted-vertical type occupying much less floor space
f diminished bulk and weight. Prominent among builders
s type is the National Gas Engine Co. of England, who
a series ranging from a 4-cylinder, 2-crank, single-acting
troke, inverted-vertical tandem design of 300 B.H.P. at
p.m. to a 12-cylinder, 6-crank similar design of 1,500 B.H.P.
ng at 200 revolutions per minute. One installation of these
nal engines aggregates 11,500 horsepower. Horizontal
ple-cylindered engines are also built; one British installa-
ncludes six 500 H.P. four-cycle, four-crank, single-acting,
ntal, four-stroke engines running at 190 revolutions per
te. Fig. 3 on plate illustrates a horizontal gas engine
two cylinders in tandem, working on a four-stroke cycle.

dium Gas Engines.—In gas engines of less than about
H.P. no essential change has occurred; there is a steady
it by many builders of a practically standard type of four-
e, horizontal, single-acting, single- or double-cylindered
e using coal gas or suction-producer gas as fuel, and em-
d in a great variety of services by the smaller classes of
r users. Designs of two-cylindered engines range in power
about two up to some 300 H.P. or over. The gaseous
s provided by many more or less waste substances, includ-
ituminous slack, peat, scrap wood, sawdust, straw, cocoa-
usks, etc. These smaller gas engines, in conjunction with
rn plant producing gas from industrial and vegetable refuse,
ery valuable in enabling complete power plants to be in-
d and successfully operated by native labour in situations
te from civilised centres.

gines Using Heavy Oils.—It is in the entirely successful
f heavy oil (petroleum oils having a flash point exceeding
t 73° F.) as fuel in internal combustion engines that the
est advance was made from 1910–25; this applied to all
s of engines, from the smallest to the greatest, and particu-
to the exceedingly important and rapidly extending marine
cations where, owing to their relative compactness and the
nce of boilers and bunkers, the space occupied by the pro-
ng machinery is greatly reduced.

he earliest heavy-oil engines as, for example, those of Priest-
(1885), Samuelson, Thornycroft, Gardner and others, in-
d a vaporiser, heated by an external blow lamp, in which
uel was gasified, and then, mixed with a suitable volume of
air, exploded within the working cylinder by a hot tube.
pression pressures were necessarily low to prevent detona-
and the fuel consumption was correspondingly high. Next
Akroyd Stuart's (1886–90) epoch-making invention,
ssfully embodied in the Hornsby-Akroyd oil engine, of
ing the hot walls of an unjacketed vessel (communicating
gh a restricted passage with the water-cooled combustion chamber of the working cylinder) first to vaporise the charge of oil fuel pump-injected into it during the air-suction stroke, and then *automatically* to ignite the resulting charge of oil, vapour, and air at the end of the compression stroke. Equally important was the progress made by the Diesel engine (see fig. 1 on plate) from 1893 in both four-stroke and two-stroke designs; the essential feature of the true Diesel is defined as the injection of the oil fuel directly into the water-cooled combustion chamber at, or about, the end of the compression stroke; air alone is compressed to a pressure of some 500 lb. per sq. in., the resulting high temperature automatically igniting the explosive mixture of air and oil spray; the fuel feed is so regulated that combustion proceeds at approximately constant pressure during a small part of the working stroke.

The oil fuel was for long sprayed into Diesel engines by an air blast at a pressure of up to 1,000 lb. per sq. in., involving compressing plant costly in production and maintenance; moreover, the high compression pressure employed necessitated extremely strong and heavy parts, and an extraordinary refinement in workmanship in order to achieve permanently satisfactory running. The efficiency attained was, however, remarkable, and considerably greater than that of any other form of internal combustion oil engine. These practical drawbacks soon resulted in the production, for smaller powers, of a large, varied and important class of engines usually termed semi-Diesels, in which the charge of heavy oil fuel is sprayed, usually by a small force pump, into the combustion chamber at or about the instant of maximum compression. The heat of an uncooled portion of the combustion chamber wall, aided by the heat generated by the moderate compression of the air, then ignites the charge automatically as in the well-known Ruston C.C., and in the two-stroke Bolinder "hot-bulb" marine engine, as used in so many trawlers, and in ocean-going boats of up to 1,000 H.P. in two units. The semi-Diesel engines combine many of the advantages of the Akroyd and Diesel types in a practical manner, and show considerable economy in running.

More recently, about 1924, it was discovered that the "hot-bulb" or "hot-spot" in the combustion chamber could also be dispensed with, allowing the whole to be water-cooled as in the vertical, Vickers-Petter, two-stroke, two-part, heavy-oil, C-type engines which are built in sizes up to 500 H.P. running at 250 r.p.m., with six cylinders. In these the charge of oil is pump-injected into a completely water-cooled combustion chamber of approximately spherical form about one-half the diameter of the working cylinder; the compression employed, though much lower than that usual in the Diesel engine, is yet great enough to cause automatic ignition of the charge, and to ensure an economical use of the fuel; the cheapest grade fuel oils are used in these engines, having a flash point above 150° F., and otherwise also in accordance with B.E.S.A. specifications. The consumption of oil at full load in the larger engines is stated to be not more than 0·43 lb. per B.H.P. hour (*see* Marine Engineering). The progress evidenced in the application of the internal combustion engine to marine purposes of all types was of a revolutionary character during the period here contemplated, and continued at a constantly increasing rate; at the end of 1925 all the great British marine engineering companies had taken up their manufacture.

Engines Using Light Oil.—This comprises the petrol motor now applied universally to the propulsion of all types of road and land vehicles, aircraft, small motor-boats, farm tractors and miscellaneous small services. For road, land and air service they were still, in 1925, almost all four-strokers, with the exception of cars in the United States, where the six-stroker is equally popular except in the lightest classes, *e.g.*, motor-cycles, small motor-boats and a few light cars in which the simple three-port two-stroker had become well established. The progress of the petrol engine from 1910 consisted mainly in the perfecting of details of design, improved carburation, charging and ignition, in lighter moving parts, and in the commercial production of fuel mixtures free from liability to cause detonation or "pinking," thus enabling much higher revolution speeds to be maintained and greater mean effective pressures reached. The success attained is indeed remarkable, tiny petrol engines rivalling in efficiency large, high-powered engines of almost any other type. Small engines of racing type have been run in contests at well over 6,000 r.p.m., *i.e.*, upwards of 50 complete cycles per sec.; and tiny four-cylinder four-stroke engines of only 2·2 in. bore and 3 in. stroke were in extensive use in small "occasional four-seater" motor cars capable of speeds, on the track, of fully 80 m. per hour! A number of very encouraging attempts have recently been made to increase power outputs still further by aid of super-charging devices. At the British Motor Car Show of 1925, 65% of the vehicle engines were four-cylindered: 27% six-cylindered: and 5% eight-cylindered. Side by side valves were fitted in 45% and overhead valves in 44% of the exhibits.

Producer Gas Lorries.—A post-War development of much interest and potential value is that of driving heavy motor lorries by small high-speed internal combustion engines of the usual type, but using as fuel gas supplied by specially designed very small suction producers mounted upon the vehicle, and using anthracite, coke, charcoal, etc., as their fuel; encouraging progress has been made in this direction.

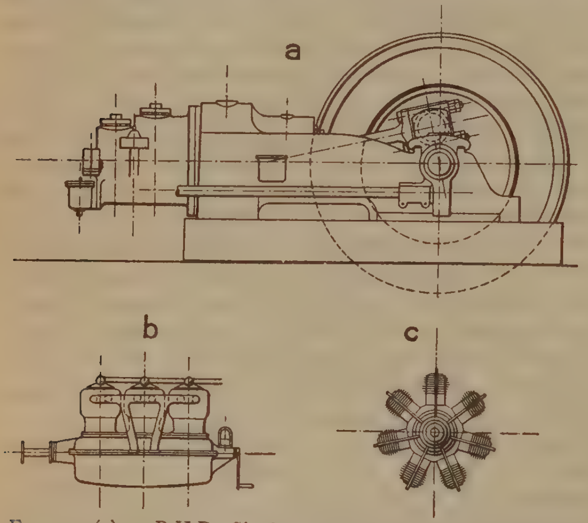

FIG. 1.—(*a*) 75-B.H.P., Single-cylinder Horizontal Engine. 200 R.P.M. Weight 200 lb. per B.H.P. Total 15,000 lb. (*b*) 75-B.H.P., 6-cylinder, Vertical, Water-cooled Aero Engine. 1,200 R.P.M. Weight 5½ lb. per B.H.P. Total 410 lb. (*c*) 75-B.H.P., 7-cylinder, Rotary, Air-cooled Aero Engine. 1,200 R.P.M. Weight 2¾ lb. per B.H.P. Total 205 lb.

Engines for Aircraft.—Characterised by their extreme lightness, these internal combustion engines display the utmost skill in design and refinements in manufacture, and important advances have been made in all details since 1910. (*See* AERO ENGINES; AERONAUTICS.)

Special Types.—Among special types of internal combustion engines may be mentioned the Humphrey pump. In 1913 an installation of five large Humphrey pumps at the Chingford reservoir of the Metropolitan Water Board commenced operations; this plant is capable of dealing with 180,000,000 gal. daily, a quantity exceeding the whole daily supply of Greater London. At the end of 1925 these pumps continued in regular service, and a second similar installation was in course of erection in Australia. The construction of a 1,000 million-gallon-per-day plant near Alexandria (Egypt) was commenced, but was not completed on account of the outbreak of the World War.

A second recent design of internal combustion engine of much interest is the Michell crankless engine oil-operated in the Diesel manner. In this engine the working cylinders are grouped symmetrically around the driving shaft, with their axes all parallel to the shaft axis, and the rotation is effected through a "swash-plate," or inclined disc affixed to the shaft upon which the several pistons act through a bearing "pad" of the well-known Michell thrust-bearing type. Engines of three, four, five, seven
and eight cylinders have been built, both of single-end
double-ended type. An eight-cylinder Michell engine of
recently built, showed on test a mechanical efficiency of
full load. The extremely great difficulties of the intern
bustion turbines still remain to be overcome, and little or
progress can be recorded in this type of motor during the
herein reviewed. (G. A.

INTERNATIONAL LABOUR ORGANISATION, THE.—T
ganisation was created in 1919 by Part XIII. of the Tre
Versailles, headed "Labour." This part was reprodu
all the later peace treaties, appearing as Part XIII.
Treaties of Saint Germain, Neuilly, Trianon, and Part
the Treaty of Sèvres. These treaties are the first known to
to contain articles dealing with labour.

I. ORIGIN AND CONSTITUTION

The idea of protecting labour by international conve
is in reality not a new one. Strictly speaking, its origins mi
traced back to the humanitarian theories of a handful of th
who over a century ago foresaw the necessity of estab
economic co-operation among the nations in order effectu
remedy the evils which might spring from the develo
of modern industry. The name of Robert Owen is often
as a pioneer of international Labour legislation on account
two memoranda which he submitted to the Congress of A
in 1818. In reality, although Owen was indisputably a p
of protective legislation for national, wage-earning L
his memoranda do not contain the idea of an understa
between governments for the establishment of identical
tive measures in favour of their wage-earners. A French
trialist, Daniel Le Grand, attempted to promote this
between 1840–60. But it was only after 1890 that
governments began to show an interest in it. A conference w
in Berlin, convened by the German Govt., but it confined it
enunciating a few very general principles. At last, in 1900 th
took form when a private organisation, encouraged and subs
by certain governments, was formed under the name
"International Association for Labour Legislation" (Ass
pour la prot. légale des Travailleurs) with headquarters at

In 1903 a technical conference summoned by the Asso
worked out two draft labour conventions, the one dealin
the limitation of night work for women in industry, the
with the prohibition of the use of white phosphorus in the
industry. In 1906 a diplomatic conference adopted these
and a few states ratified them. A new technical conf
was convoked in 1913 to regulate by new conventions the
hibition of night work for young persons employed in in
and to fix a 10-hour working day for women and young pe
The second diplomatic conference was due to assemble i
autumn of 1914. Meanwhile, the World War broke out.
the work which was taken up again and officially consecrat
the peace treaties which concluded the War of 1914–8.

Labour in the Peace Treaties.—It may be asked why c
dealing with the protection of labour were inserted in the
treaties. The pre-War movement in favour of protection of l
was not in itself strong enough to enforce it. In most coun
it was the work of intellectuals, legal experts, or politicians.
few exceptions (*e.g.*, Germany), the workers' organisations
little interest in it. But in almost all the belligerent State
War brought into prominence the share taken by the wo
classes in national defence and national life. The worker
came conscious of this fact. As early as Sept. 1914 a mani
of the American Federation of Labour declared that peace sh
not be signed without the participation of representativ
Labour. In July 1916 at a conference at Leeds, of the trad
ions of the Allied countries, again in Oct. 1917 at a confere
the trade unions of the neutral countries and the Central Po
at Berne, then again at the conference of the inter-Allied S
ists at London in Sept. 1918 the same idea was again taken

"The Treaty of Peace which will end the war and will a
to the peoples political-economic liberty and independen
said the London Manifesto, "must also safeguard the wo

f all countries from the attacks of international capitalist iton and assure it a minimum guarantee of moral and d order as regards labour legislation, trade union rights, on, social insurance," etc.

ediately after the War these tendencies grew far more pro- d. Revolutions had broken out in the conquered coun- nd their character had been invariably social. In the ous countries the leaders of the governments pronounced, rdance with the general feeling, that "the old world must ind that the working classes must receive a new place in tional communities. In Feb. 1919, at Berne, the trade of all European countries, allied, neutral, or defeated, d a labour charter and suggested that the old association, s labour office, should be transformed into a great official ation of international labour legislation. A few days (Jan. 29 1919) the peace conference had resolved to con- a commission for international labour legislation under esidency of Samuel Gompers, and had called on it "to e into the international means necessary to secure common on matters affecting the conditions of employment." The ssion sat from Feb. 1–March 24 1919. It worked out a text having been adopted by the peace conference on April 11 1919, became Part XIII. of the Treaty of Versailles.

iciples and Procedure of the Organisation.—A preamble head of Part XIII. defined as follows the principles which irth to the organisation.

> niversal peace, which it is the object of the League of Nations blish, can be established only if it is based on social justice, cial justice implies the working out of equitable conditions of which it is urgently necessary to apply.
>
> he regulation of labour conditions can be accomplished only tionally because "the failure of any nation to adopt humane ons of labour is an obstacle in the way of other nations which to improve the conditions in their own countries."
>
> he equitable conditions of labour, and the "humane condi- f labour," which must be applied were defined: the establish- of a maximum working day and week, the prevention of loyment, the provision of an adequate living wage, the pro- of the worker against sickness, disease and injury arising his employment, the protection of children, young persons, men, provision for old age and injury, protection of the in- of workers when employed in countries other than their own, ition of the principle of freedom of association, the organisa- vocational and technical education and other measures.

nother article (427) of the Treaty of Peace, these principles mulated afresh and in a more precise form and recognised ell fitted to guide the policy of the League of Nations" in rial matters. These principles having been laid down, the Treaty prescribed that a permanent organisation should ablished for their promotion. The commission, on meeting is, was approached with proposals emanating from work- presentatives and even from certain States (such as Italy) aimed at permitting a sort of international Parliament to labour conditions which every State would be compelled pt. Such proposals appeared incompatible with the idea ional sovereignty as entertained by most states. The In- ional Labour Organisation, it was thought, should not a "super-state," any more than the League of Nations. ommission adopted as a basis of its deliberations a British which was more modest and, above all, more elastic, and pted to reconcile the independence of individual States he authority of an official organisation.

e system adopted was as follows: The International Labour isation consists of two essential organs: the General Con- e of Representatives of the Members, and an International r Office controlled by a Governing Body. The conference "from time to time as occasion may require and at least n every year." It is composed of four delegates of each of ember States, of which two are government delegates and wo others represent respectively the employers and the eople. These last two delegates must be chosen by the nments in agreement with the industrial organisations, if organisations exist, which are most representative of em- rs or workpeople, as the case may be, in their respective ries. This shows a characteristic feature of the new organisation. In the Assembly of the League of Nations only Government delegates have seats, but here delegates representing the employers and the workpeople of the member states intervene. This indicates the solidarity of economic and protective forces which has imposed itself on the world since the War.

The conference deals with questions which have been included in its agenda by the governing body, and the agenda is transmitted to the member governments four months before the meeting of the conference. At the close of its discussions it may adopt Recommendations or Draft Conventions by a majority of two-thirds of the votes cast by the delegates present, but not otherwise. The member states undertake that, within a year at most from the closing of the Session of the Conferences, or if special circumstance prevent this, in no case later than eighteen months, they will bring the Recommendation or Draft Convention before the authorities within whose competence the matter lies, for the enactment of legislation or any other action. In the case of a Recommendation the member states will inform the Secretary General of the League of the action taken. In the case of a Draft Convention the member will, if it obtains the consent of the proper authorities, communicate the formal ratification of the Convention to the Secretary-General and will take all necessary action to make the Convention effective. In the case of a Convention the obligations which are assumed by member states on ratification are far stricter.

It is necessary to consider the exact weight which the system carries. The States, under the Peace Treaty, have not undertaken to ratify automatically all draft conventions adopted by the international Labour conference. They have simply undertaken to submit the drafts to the authorities competent to enact the legislation. Here lies the essential innovation. Finally, they are still free to ratify or not. But when there was only the International Association for Labour Legislation, before the War, the States which had sent plenipotentiaries to the diplomatic conferences were not even bound to approach their Parliaments with the resolutions adopted. Now they have undertaken this obligation. This obligation may seem to carry little weight, since each State remains free, within its sovereign rights, to ratify or not. But in essence the whole system rests on an appeal to the public opinion of each of these States, and an appeal to Parliament, which is, so to speak, the authoritative expression of this opinion. The whole mechanism invented by the negotiations of the treaty constitutes an act of faith in the feeling of justice which should animate corporate humanity.

Once the conventions have been ratified the mechanism of their application instituted by the Peace Treaty develops in the following manner: by the act of ratification the States contract a mutual agreement to respect equally all clauses contained in a convention. They must allow mutual supervision of their application of these clauses. By Art. 408 of the Treaty of Versailles they undertake to send an annual report to the conference in which they give a list of the measures for their application. Comparison of these reports may always form the subject of discussion at the conference. If one of the ratifying States fails to apply the convention, or applies it imperfectly, other ratifying States, or even industrial associations of employers or of workers may file complaints. When such complaints are received, the governing body of the international Labour office is charged to deal with them. If necessary it may submit the complaint to a commission of inquiry (Art. 409 and 414). In the last instance, the Permanent Court of International Justice can be called on to pronounce judgment. This court may even, under Art. 418, indicate the measures, if any, of an economic character which it considers to be appropriate and which other governments would be justified in adopting against a defaulting government.

II. THE I.L.O. IN OPERATION

The first conference was convoked at Washington in Oct. 1919. The international office was not yet constituted. The programme of the conference had been fixed in the peace treaty itself. A committee of organisation had been entrusted with its preparation. Six draft conventions were voted concerning:—

1. The limitation of hours of work in industrial establishments to eight hours a day and 48 hours a week.
2. Unemployment.
3. The labour of women before and after child-birth.
4. Night work for women.
5. The maximum age for the admission of children to industrial labour.
6. Night work for children in industry.

The Washington conference constituted the International Labour Office, and nominated its first governing body. This governing body appointed the director, M. Albert Thomas. In 1920 a conference was held at Geneva, which was devoted to maritime questions and passed three draft conventions. The first fixed the age of admission to work at sea, the second dealt with unemployment benefit in case of loss by shipwreck, the third dealt with finding employment for sailors.

In 1921 the third session at Geneva voted seven draft conventions dealing with:—

1. The age of admission for children to agricultural labour.
2. The right of combination and coalition of agricultural labourers.
3. Compensation for accidents incurred during work in agriculture.
4. The use of white lead in paint.
5. The application of the weekly rest to industrial establishments.
6. The age of admission of young persons to employment as trimmers or stokers.
7. The compulsory medical examination of children and young persons employed on board ship.

Each of these sessions voted at the same time a number of recommendations.

The fourth session at Geneva in 1922 only voted a recommendation concerning statistics and documents relative to emigration and immigration. The fifth session at Geneva in 1923 also voted only one recommendation concerning general principles for the organisation of inspection services destined to ensure the application of laws and regulations for the protection of workmen. The sixth session at Geneva in 1924 instituted the procedure of giving the conventions two readings, at intervals of one year. Some conventions were thus given a first hearing, most of them being voted in 1925. The session of 1924 only definitely passed one recommendation concerning the utilisation of the spare time of workmen. The seventh session, Geneva 1925, finally voted four draft conventions concerning (1) compensation for accidents arising out of employment, (2) compensation for sickness arising out of employment, (3) equality of treatment for workmen when employed in countries other than their own as regards compensation for accidents incurred during work, (4) night work in bakeries.

In all, then, not counting recommendations, twenty international Labour conventions were submitted to the States for ratification between 1919 and 1925. These conventions dealt with industry-commerce and in some cases navigation and agriculture. As regards agriculture a dispute arose in 1921. It was maintained that the international Labour organisation had not the right, under the Peace Treaty to deal with the protection of agricultural labourers. On this point the advice of the Permanent Court of International Justice was taken through the mediation of the League of Nations under Art. 14 of the Peace Treaty. The permanent court gave a judgment recognising the competence of the International Labour Organisation.

Ratifications.—In what proportion have the States ratified these conventions by the procedure indicated above? In March 1926 the League of Nations had registered 194 ratifications. This figure has given rise to much discussion. It is important to gain a just estimate of its worth. The International Labour Organisation includes 56 States. If one excepts the four last conventions of 1925, which could not be ratified by the time of writing, about 900 acts of ratification could in theory take place for the other 16 conventions. There are only 194—that is, about one-fourth. But this low figure calls for certain remarks. The same value cannot be attached to all ratifications.

1. There are a certain number of conventions which could not be ratified by all States, despite their general character. The maritime conventions, for example, do not interest the States which have neither coasts nor fleets. Similarly, there are countries of small proprietors where the number of wage-earning agricultural labourers is quite insignificant. There are others, again, where certai healthy industries against which conventions are directed ha established themselves.

2. There are numerous States in which industry is of litt portance and where national labour legislation hardly exists. Hedjaz, Siam and other States have indicated that the measure down in certain conventions are inapplicable to the conditions which the wage-earning labourers in these countries work.

3. International action is only beginning, and all sorts of re delay ratification; not merely the inexperience and inattenti the great national administrations, for which the interna conventions are often matters of secondary importance, bu the hesitation to contract obligations which sometimes appe threaten the output or at least the competitive capacity country on the international market. But in spite of these important results have been obtained.

In the eight years preceding the War the two conventio Berne had only been ratified by a very few States. When such conventions as that which forbids night work for w or that which attempts to cope with unemployment obtai ratification of 16 or 20 states, including great industrial cou like Great Britain, France or Italy, many thousands of men are definitely assured of the enjoyment of the bene reform. For, under the text of the conventions, the contr States cannot, for a period of 10 years, go back on the oblig which they have assumed, even in crises where they wou tempted to do so. The effect of the ratifications has been particularly important in certain countries, for example in where the conditions of labour have been greatly improve the application of the measures contained in the internat conventions such as that of Washington.

But even when the conventions are not ratified, they be the model on which the new national legislations form themse A country such as Belgium, for example, has established eight-hour day, which was voted in 1921 in strict conformity the clauses of the Washington Convention. Similarly, all young States of Central and Eastern Europe which were fo or resuscitated in 1919 have modelled their entire labour leg tion on the general rules laid down by the International La Organisation. It seems, then, that despite the difficulties inhe in its first constitution and despite the economic crises most nations have gone through since 1920, the work ac plished by the unification of labour conditions on a relati high level by the organisation has had appreciable results.

A Centre of Information.—The work of the International La Organisation is not confined to preparing the international ventions, to seeking to obtain their ratification by the States, watching over their application. Art. 396 of the Peace Treaty assigns it further functions which include the "collection and bution of information on all subjects relating to the internat adjustment of conditions of industrial life and labour." Also conduct of such special investigation as may be ordered by the ference." It has "to edit and publish in French and English pe ical publications." The conference may even assign to it, bes the functions mentioned above„ "such other powers and dut as it chooses.
